Lectures and Addresses.

THE PROPER SCOPE OF SCIENTIFIC (SO CALLED EXPERT) TESTIMONY IN TRIALS INVOLVING PHARMACOLOGICAL QUESTIONS.*

By SOLOMON SOLIS COHEN, M. D.,

PHILADELPHIA,

PROFESSOR OF CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE.

Mr. President and Gentlemen:

It is by request of your committee of invitation that I shall devote the address I have the honor to make to you to-day to the consideration of the subject of "expert testimony" in certain of its relations having a common interest for physicians and pharmacists. My criticisms will be addressed principally to our own faults, not those of others. Doubtless there are many motes in the eyes of the lawyers; but before we begin to discuss the best method of extracting them, let us try to discover how we can get rid of the beams that tend to make our own vision oblique.

It is not to be denied that the "medical expert" or "chemical expert" witness is often an object of suspicion to courts and juries; that lawyers out of court find no impropriety in ridiculing him, while in court, if he is on the other side, their attitude toward him is not invariably one of the highest respect for his knowledge or his devotion to the truth. Moreover this unflattering estimate of the sincerity of the expert witness is not confined to courts and lawyers; it is reflected in the press and in the comments of the man in the street. It would be soothing to wounded vanity to attribute the distrust of expert testimony entirely to the obscurity of the difficult scientific questions so often involved and the inadequacy of the legal methods of the day for the development and presentation of such questions. Undoubtedly these impersonal elements are important factors; but it must be admitted that there are also personal factors, and that for the latter physicians and chemists are not without blame. When

* An address delivered before the Philadelphia College of Pharmacy.

men of equal reputation and competence can be found, apparently in any desired number, to form either of two opposite opinions upon the same apparently simple set of facts; can be induced to express positive and conflicting views upon questions concerning which the evidence is insufficient for the formation of a positive view of any kind; and are willing, moreover, to suggest to an attorney questions that seem to have no other purpose than to confuse scientific colleagues who may appear as witnesses on the other side, or unfairly to impugn and belittle the evidence given by such colleagues—is the assumption wholly without plausibility that the nature of the testimony given by any expert witness is in effect determined by the necessities of that side of the case upon which he is employed? We know and many attorneys know that, despite its plausibility, the assumption is far from being correct. But that is because we and the attorneys know what the newspapers and the public do not know and cannot know; namely, how often physicians and chemists refuse to testify in behalf of interests that have consulted them, because on examination of the facts they find that they cannot truthfully give the testimony desired. That incompetent, inaccurate, overzealous, or even untruthful persons sometimes appear in the rôle of expert witnesses, playing it very much to the satisfaction not only of their employers, but also of the jury and the spectators—may be admitted. With this phase of the subject, however, I do not purpose to deal at this time. I shall consider only the difficulties besetting competent men, desirous to tell the truth and nothing but the truth, when they enter the witness box to instruct courts and juries upon pharmacological and toxicological questions.

In the first place, it is often requisite to state technical facts in untechnical language. There is much difference between lack of technicality and simplicity. The simplest statement is always the best; but the untechnical statement is not always the simplest; frequently it is the most complex. Consider for a moment only the physical and chemical questions of osmosis, of atomic weight, of valency, of crystallization, of stereochemistry, of ionization, or

the pharmacological questions of the effects of drugs upon metabolism or upon cell structure. How can such matters be expressed in other than technical terms, and yet be expressed both clearly and adequately? The only way out of the difficulty is not to try to get out of it. Let us state our technical position for the record, as simply as possible; that is, in technical terms. We may then explain in untechnical language for the jury. One common result of the effort to avoid technical statements is a multiplication of words from which juries, even more intelligent than the average, can gather no clear idea. Another is an impossible simplification of a difficult problem, which is consequently, even though a correct conclusion is reached, open to just criticism—a *fortiori* to captious criticism. Just here comes to light one grave fault of medical and chemical experts. We are too prone to make and to suggest that very kind of captious criticism of the testimony of an opposing witness, not for the purpose of eliciting truth, but in order to score a point in the game. Such tactics may be perfectly proper on the part of an advocate, but not on the part of one who professes to be impartially devoted to science.

And this brings into view a second difficulty. Theoretically, the expert witness is an adviser of the court. He is called in, because of his supposedly superior knowledge, to help the judge and jury to understand the significance of certain facts testified to by himself or others, which cannot be understood without such assistance. He should have no interest in the bearing of these facts upon the verdict to be rendered. Was or was not arsenic present in a certain liver or stomach examined by him? Do or do not certain post mortem appearances or certain symptoms observed during life indicate death from poisoning? Is or is not the continuous and unsuspected administration of unknown quantities of boric acid or salicylic acid or sodium sulphite injurious to health? These and like matters are the subjects upon which he is called to state judgments of fact or to express opinions, and in consequence to detail the observations and explain the reasoning upon which such judgments or opinions are based. But his interest in the matter should be entirely scientific. It should be no concern of his, as a witness, whether the presence or absence of arsenic in the tissues or other materials that he has examined, or the significance of the symptoms described, or the harmfulness or harmlessness of chemicals used as food preservatives, may lead to the conviction or acquittal of any individual or the gain or loss of any commercial interest. His function in court is quite clear. It is (a) to describe the methods and the results of his examinations; (b) to state the conclusions that his study and observation in gen-

eral enable him to draw from a given set of facts observed and described by him or testified to by others; (c) to enlighten the court as to matters of scientific knowledge relevant to the issues presented, but not dependent upon any testimony as to fact given in the special cause at trial. Beyond that his testimony, his advice, his interest, should not go.

Under present methods, however, the expert witness is not summoned in his theoretical capacity of impartial teacher and adviser. He is called apparently, and often in reality, as a partizan and an advocate. Indeed, whatever his own view may be as to his relation to the case, he is usually regarded and treated as a partizan and advocate by judge, jury, lawyers, spectators, and newspapers. How often do we read in great headlines of the "Battle of the Experts!" How often is the speculation heard, privately or publicly, as to whether the prosecution or the defense will "get Dr. A," with the implication that the other side will then necessarily "get Dr. B," and that Dr. A and Dr. B will, of equal necessity, express in court opposite opinions on the same facts.

There is unquestionably a legitimate field of work for the scientific or "expert" advocate; but it is by the side of counsel, not in the witness box. As witness one is bound by his oath and by his duty to the court and to the State to endeavor to assist judge and jury to reach correct conclusions, without reference to the effect of those conclusions upon the verdict to be rendered. He is to distort nothing, magnify nothing, minimize nothing; assert as positive nothing doubtful, throw doubt upon nothing certain; introduce nothing irrelevant, suppress nothing material; give utterance to no statement of fact, advance no theory, that he would shrink from defending before a learned society. But as advocate, one may properly consider the bearing of testimony upon the verdict and endeavor to have judge and jury impressed with the especial importance of those facts and theories making for his side of the case, and with the doubtfulness and unimportance of those making for the opposing side. The functions of the witness and of the advocate should therefore never be united in the same person. Human nature being what it is, however, our present methods tend to imbue expert witnesses with somewhat of the advocate's spirit. Some do not realize this tendency; others despite their effort to avoid partizan advocacy are badgered into it by the unfair efforts of cross-examiners to throw doubt and obscurity upon their direct testimony. Unfortunately these efforts are sometimes instigated and directed by the expert witnesses of the other side.

The remedy for this difficulty lies wholly in our own hands. It will not do to abuse the lawyers for

it, however much they may abuse us when we are on the witness stand. Use, abuse, or misuse what and whom they will, they cannot make use of us for any purpose for which we refuse to be made use of.

A third order of difficulties has been alluded to, but may now be considered more fully. It is often assumed that expert witnesses are not called to give testimony as to fact, but merely to express opinions, and that hence opinion may properly be set against opinion. This is but partially true. Expert witnesses are frequently called to express opinions upon facts which they must themselves first testify to; or to express judgments of fact—and not opinions at all—upon investigations that they have themselves made. This is especially the case with chemists and pathologists. We can here confine our attention to chemists.

A chemist or pharmacist may be asked, for example, to make certain analyses in order to determine the purity of pharmaceutical products, or to ascertain whether foods or articles of commerce have been adulterated or have had foreign substances added to them to color, disguise, or preserve them; or to discover whether certain substances—sometimes human tissues—contain poison. He submits the suspected articles to certain physical and chemical manipulations; examines them with the naked eye, with the microscope, with the spectroscope, and otherwise. Upon the results of these examinations he forms a judgment. When describing in court the methods and results of his examinations, it will be generally admitted that he testifies as to facts. How about the judgment he has formed? That judgment, when stated in court, is commonly treated as an expression of opinion. In reality it is a judgment as to fact, as valid as any other judgment as to fact that can be made the subject of testimony. It differs from ordinary judgments in that special skill and knowledge are required, first, to obtain its data and, secondly to understand their significance; but so do many other judgments that we never think of treating as matters of opinion—which are indeed recognized to be therefore more accurate, not more dubious, than ordinary judgments; for example, that of a navigator as to the position of his ship, or of a surveyor as to the dimensions of a certain plot of ground, or of a skilled weigher as to the number of pounds contained in a heap of coal. The differences that may exist among these various judgments are not those of kind, but merely of degrees of complexity. Such judgments may be mistaken; but that, while it subjects them to correction, does not remove them to the category of opinions—unless the term opinion be extended to include every mental operation in the nature of a judgment.

Testimony concerning chemical analysis and its results is properly to be subjected to criticism as to the pertinency, correctness, skill, and accuracy of the manipulations and as to their conclusiveness; but such criticism deals with fact, and must be kept within due bounds. It is perfectly proper to point out, for example, that in the attempted identification of poisons, a careless observer may mistake antimony for arsenic; but it is misleading—and a competent chemist must consider it deliberately so—to attempt to make a jury believe that discrimination between arsenic and antimony is at all uncertain when the right tests have been made with due care and intelligence. It is not in any degree a matter of opinion, subject to debate and dispute, but an acknowledged fact of science. No expert should lend himself to a pettifogging practice of the nature described.

Again, it is proper to point out and inquire about all sources of error in manipulation, but undue insistence upon widespread contamination of vessels and reagents with, for example, arsenic, can be considered only captious criticism in the presence of statements that due care has been taken by blank tests and otherwise to exclude that source of error and when amounts have been found not to be accounted for even approximately by these common contaminations. I have elsewhere suggested that important examinations by official analysts should be made in the presence of experts representing the other side; or that both sides should, in cases in which this method is possible, be permitted to have analyses made by their respective experts. The further suggestion was also made that the results of final and decisive tests should be required to be preserved for exhibition and criticism in court. Such procedures would go far, I think, to avert the sort of criticism here deprecated and also to guard against incompetence, carelessness, or error, on the part of official or other partisan analysts.

Opinions may in certain cases of chemical analysis differ as to the scope and conclusiveness of special tests. In all such cases it is a simple matter for the expert witnesses on both sides to state the issue, first in technical terms for the record, secondly in non-technical terms for the enlightenment of court and jury, and in such a way as to make clear the exact point in dispute and its bearing on the final judgment of fact. It is also easy to take the opposite course in order to becloud the issue. Were the straightforward, scientific, impartial way obligatory in every instance, many issues which have been allowed to occupy much of the time and attention of courts and juries would at once be shown to be based on trivialities of no possible importance in the cause at trial.

Still another source of confusion between fact

and opinion arises from the questioning of expert witnesses as to what may be termed facts of science, and the failure of courts to rule uniformly as to just what testimony of this kind is admissible and what is inadmissible. One court will permit the widest and wildest latitude; another will exclude as "hearsay" all matters outside the personal experience of the expert witness. I do not purpose to discuss these conflicting rulings from a legal viewpoint. Shall doctors decide when judges disagree? But I may be permitted to point out the logical and scientific difficulties involved in both positions.

First let us consider the position of an expert witness called upon to differentiate between the knowledge he has obtained from reading and that which he has acquired by personal observation. How far a chemist or pharmacist may be able to do this, I do not know. If you have all verified by balance-tests and other appropriate methods the atomic weights, the valencies, the electric positions, and other properties of all the elements, and the structures of all the compounds, perhaps you may begin to think of qualifying under the "no hearsay" rule. I doubt, however, whether any physician could state accurately how much of the composite pictures he carries in his mind of the symptomatology and pathology of diseases and of the effects of drugs—even a disease so common as typhoid fever or of a drug so much used as opium or mercury, is based upon cases personally observed, to the exclusion of those read about. One of the best known pathologists in America, a man of enormous experience, told me that he had never personally made a post mortem examination of a case of combined sclerosis of the spinal cord, although of course he had seen and studied sections of cords from such cases. Some physicians have never seen a case of infantile scurvy; but they know that the affection exists and that it gives rise to discolorations of the skin that are often mistaken for bruises, and upon which unfounded charges of cruelty to children may be brought. I have never examined a thyroid gland for iodine or arsenic, yet I know that iodine is constantly and arsenic sometimes found in thyroid glands of men and animals, apparently in each case as a normal constituent. If the question of the possible presence of iodine or arsenic in normal thyroid glands should be of importance in a given trial, could I not properly state my knowledge as book knowledge? Must one send for Mendel or Gautier to testify to personal analysis? I have never seen an insane person commit homicide or suicide, yet I have testified in court that certain persons ought to be kept under restraint lest they should kill themselves or others and I believe the testimony was properly made and properly accepted. Would not the "no hearsay"

rule exclude this testimony also? Even had I seen the dead bodies of insane suicides or of the victims of homicidal maniacs, that fact would not seem to remove my knowledge from the hearsay category; nothing would do that except actually seeing the killing. I know that arsenic poisoning has been caused by contaminated beer, by wall paper, by stockings, though I have never analyzed beer, wall paper, or stockings for the presence of arsenic. I know that in this city fatal lead poisoning has been caused by cakes colored with chrome yellow, though I did not see any of the cases. I have not even seen the men at work painting or making lead whom I have treated for lead poisoning acquired in such occupations.

That iodine is a constant normal constituent of the thyroid gland and that Gautier, Bertrand, and others have found arsenic in the normal thyroid gland and other normal tissues; that maniacs have committed homicide and suicide; that arsenical poisoning has been caused by contaminated beer—are facts, not opinions. They are facts known only or best to certain persons because those persons have made special studies involving the knowledge of such facts; and whatever the law may be, it would appear reasonable that such facts should, when relevant to the issue, be testified to in court by qualified persons as parts of the sum total of the knowledge acquired by their reading and observation. On the other hand, when a fact of this nature is uncommon it is perfectly proper to bring out its rarity, and, if such is the case, to show that while an integral portion of the witness's knowledge it is outside of his personal observation.

(To be concluded.)

Brooklyn Hospital Saturday and Sunday Association.—Through its treasurer, the Brooklyn Hospital Saturday and Sunday Association reports a gratifying increase this year over the amount received last year. The amount received up to last night was \$1,272.60. This money is received from all sources—churches, lodges, clubs, business firms, and from individuals. The association was organized twenty-four years ago to secure contributions to various hospitals in Brooklyn. It takes its name from the fact that the last two Saturdays and Sundays of each year are appointed as the days on which to receive contributions. The following fifteen hospitals are beneficiaries of the association: The Brooklyn Hospital, Long Island College Hospital, Eastern District Hospital, Brooklyn Maternity, St. John's Hospital Home for Consumptives, the Memorial Hospital, Lutheran Hospital Association, Norwegian Lutheran Deaconesses Home and Hospital, House of St. Giles the Cripple, the Infants' Hospital, St. Christopher's Hospital for Babies, Williamsburg Hospital, the Methodist Episcopal Hospital, the German Hospital.

Original Communications.

POISONING BY WOOD, OR METHYL ALCOHOL AND ITS PREPARATIONS AS A CAUSE OF DEATH AND BLINDNESS; A SUPPLEMENTARY REPORT.

By CASEY A. WOOD, M. D., D. C. L.,

CHICAGO,

PROFESSOR OF CLINICAL OPHTHALMOLOGY IN THE UNIVERSITY OF ILLINOIS.

Quite recently a large number of instances of death and several cases of blindness in the survivors have resulted from the ingestion of wood alcohol used as an adulterant.

Perhaps the most important of these recent intoxications *en masse* have been the deaths from methylated whiskey of some twenty people in New York city and fifteen (fourteen men and one woman) in Jurjew¹ (Dorpat), Russia. As a part of this wholesale intoxication there were three cases of blindness in Dorpat and an unknown number of toxic amblyopes in New York.

Inasmuch as not more than three cases of serious poisoning from wood alcohol had until June, 1904, been known in Great Britain and the continent of Europe²—two (1899) in Germany and one, still earlier, in France³ (1877)—these recent Continental poisoning cases should be of unusual importance in the eyes of health officers and toxicologists. The meaning of it is quite plain. In Russia, as in America, "purified" or "deodorized" wood alcohol (wood spirit deprived by chemical processes of its nauseous odor and taste) is at last for sale in drug stores and spirit shops. It is probable, also, that it is beginning to be used in Russia as a substitute for grain alcohol in many of those mixtures, domestic, proprietary, and official, which, we now know, enter into the composition of adulterated American drinks and condiments, into the essences, the cheap whiskey, the perfumes, the flavoring extracts, and the patent medicines. One may confidently predict that this form of wholesale poisoning, until a few months ago confined to America, will soon be common enough in Europe. As soon as European makers and vendors of spirituous mixtures, *intended or not for external use, but capable of internal consumption*, can (without easy detection)

adulterate with a portion of the cheap 20,000 barrels of "deodorized" wood alcohol yearly exported from this country, we are almost certain to have, in Europe, additional examples of wood alcohol poisoning.

The story of the Dorpat holocaust, inasmuch as it so closely resembles the New York tragedy, is of considerable interest to us and I shall take the liberty, in the light of our own experience of such cases, of commenting on Ströhmberg's report.

At the beginning of June, 1904, while the troops were being mobilized in Jurjew, an unknown number of men and women celebrated the event by indulging in a drink known in Russian Livonia as Kuntzen's balsam. This is a popular domestic remedy variously compounded of such fragrant herbs as salvia, peppermint, rosemary, lavender, etc., with water and 50 per cent. grain alcohol. Like some of our own patent and domestic "liniments," it is employed for both internal and external use. On occasions, also, it is drunk in Livonia just as thirsty souls in America, when more legitimate beverages are not available, imbibe alcoholic nostrums (whose names I do not care to advertise here) as well as Jamaica ginger, bay rum, Cologne water, and lemon extract. As long as these fluids are concocted with grain alcohol a simple intoxication is the consequence; compounded with "deodorized" or "purified" wood alcohol, death and blindness are usually the result.

The amount of wood alcohol drunk by the Dorpat victims was small. It could be estimated in at least five instances with sufficient accuracy. One woman, who died, drank during the day, on June 21, 1904, 125 grammes of Kuntzen's balsam. Three of the dead men imbibed most of 1,200 grammes. These three were joined by a fourth, who participated in the spree and probably also took about 400 grammes. Another death resulted from drinking 150 grammes. One man, who barely escaped with his life, drank on one day 7½ grammes; on the second day, 15 grammes. Another of the survivors became blind. He took only a "swallow" of the mixture. A third survivor, who with three friends altogether consumed 60 grammes, say 15 grammes for his share, also became blind. Assuming that the same quantity of wood alcohol was substituted for the grain alcohol in the balsam (i. e., one half to three fourths wood alcohol) we have from 75 to 200 grammes as the lethal dose of methyl alcohol in these cases. As it was not possible to obtain samples of the particular balsam drunk by the patients no analysis could be made; conse-

³ Viger. L'Année médicale. June, 1877; later the ocular condition of this patient (optic atrophy) was described by Mengin in the *Recueil d'ophtalmologie*, p. 636, 1879.

quently the actual quantity of pure wood alcohol imbibed could not be absolutely estimated. It may easily have been less than the amounts stated. Ströhmberg thinks 35 to 60 grammes "and more" to be a closer estimate.

A small quantity of the balsam appears to have produced blindness in at least one case. As in the American instances a fair percentage of the drinkers escaped without serious lesions.

The ages of the patients varied. The majority (10) were in the prime of life, 30 to 50 years old. One was 19 and another 80 years old. The woman who died was 60 years of age; the three blind men were, respectively, 34, 35, and 43 years old.

The symptoms corresponded exactly with what we know from a wide experience in America of this poison to be characteristic of poisoning from imbibing imperfectly "deodorized" wood alcohol. The preliminary period of exaltation, that commonly follows drinking of ethyl alcohol, seems in these cases to have been wanting. Almost immediately after the ingestion of the methylated balsam a nauseating, burning, bitter taste was experienced. This extended from the throat, along the œsophagus to the stomach; the dose was not followed by the warm, comfortable sensation in the abdomen that follows the drinking of ethyl alcohol. The patients complained of depression, weakness of and severe pains in the extremities (8 cases), headache (9), and vertigo (8). Although unsteadiness of gait marked most of the cases, seven of the patients did not present this symptom.

The heat and discomfort behind the sternum increased, in eight cases, to severe and even agonizing pain in the stomach and breast. Shortly (generally in a few hours) after taking the poison a feeling of general weakness (12 cases), and drowsiness (6) with chills (6) were noticed. In the milder cases these symptoms were delayed, but as a rule they appeared at once or at the latest the day after drinking the poison. The patients were quite ill and could no longer go about their usual work. A sensation of chilliness came on and increased until a decided rigor resulted. In one case this symptom was succeeded by fever and sweating. The weakness and chilliness usually lasted several days and the languid sensation generally deepened into semiconsciousness. The patients soon betook themselves to bed and sank into a stupor from which they were, now and then, aroused by attacks of abdominal distress and vomiting (in 13 cases). In 9 instances they complained of nausea, pains in the abdomen (12), and difficulty of breathing. They

almost constantly threw themselves from one side of the bed to the other in the vain hope of getting relief.

About this time the eyesight was affected, usually in the shape of a cloud before the eyes. This important diagnostic symptom was elicited in an unusually large percentage of the Dorpat cases, twelve in all. In two instances it deepened into complete blindness after 48 hours, without any preliminary clouding of sight. In two other cases the blindness gradually increased for five or six days. The complete amaurosis lasted from several days to a week. The ability to distinguish colors continued relatively late in the illness and either returned to normal or was entirely lost. The pupils did not react normally to light, but were in no case dilated *ad maximum*. Nevertheless, in two cases only were there undilated pupils. Twelve complained of severe pains and tenderness in the abdomen without diarrhoea; the others experienced most pain in the lower extremities, alternating with cramps of the leg muscles. Pains in the eyes were infrequent, occurring in two cases only. The face, generally red with cyanotic areas, sometimes bore a suffering, sometimes an apathetic appearance. In all cases there was no appetite, but generally much thirst. The urine of two patients in the hospital was examined. It was found to be normal, but, unfortunately, no tests were made for formic acid. Pohl⁴ found this agent in animals poisoned by wood alcohol. In another case, outside the hospital, albumin in large quantities was discovered. In our American experience, albuminuria is a common result, or coincidence, of methyl alcohol intoxication.

The pulse exhibited nothing abnormal. Generally it was (3 cases) about 60, although in a few (2) instances it reached 98.

Disturbance of breathing (10) was far more noticeable than an abnormal pulse rate. It is likely that this early sign of methyl intoxication was due to pulmonary hyperæmia. Although at first the breathing was rather labored the sense of oppression was not marked. However it soon became difficult, irregular, and superficial; shallow breaths alternated with deep inspirations. Before long there was rattling in the throat, followed by coughing and expectoration of much fluid, foamlike sputum. Finally, there was general cyanosis (5 cases), the extremities exhibited a lowered temperature, and the whole body was covered with a cold sweat. In some cases (5)

⁴ Ueber die Oxydation von Methyl- und Aethylalkohol im Tierkörper. *Archiv für exper. Pathologie und Pharmakologie*, Band 31.

complete unconsciousness set in half an hour to three hours before death; others (4) exhibited only stupor. Some patients were quite conscious at the time of death. Eight victims died within twenty-four hours after drinking the methylated balsam; two others were dead within forty-eight hours.

Three survivors of the debauch presented themselves for treatment. One of them had the usual, early symptom of irregular and difficult breathing, but it improved towards the end of the second day and became normal on the third day. Although he was able to take some nourishment at the end of the third day he experienced most of the typical symptoms, including the amblyopia, of wood alcohol poisoning. His blindness became complete on the sixth day. Another man who recovered had even a narrower escape from death. He became unconscious, and exhibited very labored, noisy breathing. At last he began to expectorate a large quantity of watery mucus, and at the end of two days showed decided improvement in his condition. In spite of this relief from the most urgent and dangerous symptoms the other signs of the intoxication persisted for a long time. These were especially blindness (optic nerve atrophy), vesical catarrh, marked nervous symptoms, headache, irregular pulse, pains in the shoulders and lower extremities associated with cramps in these organs. He also complained of persistent numbness, formication, and other paræsthesiæ of the extremities, which began on their dorsal aspect and extended to the forehead, neck, and back.

Thirteen autopsies were held. Ströhmberg is much impressed, as every one must be who studies this subject, with the uniformity and striking clearness of the picture presented by the lesions of wood alcohol poisoning.

In practically all the cases (12) the death spots were livid red, darker than in carbonic oxide poisoning. The *rigor mortis* was (in 10 cases) well marked, "goose flesh" (10) being distinctly noticeable. The face had a peculiar cyanotic color, distinct in five, not so well shown in seven cases. The pupil was of medium width (8); in two instances much dilated; in three others unaffected. The mucosa of the lips and mouth was unaffected (10); in two cases whitish.

On opening the various cavities there was in no case the characteristic odor of either ethyl or wood alcohol, aldehyde, or formalin. It may be said, in passing, that when "deodorized" wood alcohol is taken in comparatively small quantities mixed with aromatic oils (as is the case in Kuntzen's balsam, essence of peppermint, bay

rum, etc.), the aroma of the essential oils completely masks, inside or outside the body, the ethereal smell of the methyl alcohol.

The blood vessels of the mucous membrane lining the fauces, larynx, and trachea were injected. The heart was found relaxed (12); in two cases ecchymosed areas were found on its surface. In every instance (13) the blood was cherry red, thinner than normal blood, but not quite so thin as the post mortem blood of asphyxia. The lungs were hyperæmic and markedly oedematous. The stomach and bladder contained nothing characteristic. The mucosa of the stomach was hyperæmic, either in isolated patches (6), ecchymoses (4), or was rose colored throughout. It was unaffected in two cases. The same condition prevailed in the duodenum. Spleen (12) and liver (10) were hyperæmic.

Both the papillary and cortical substances of the kidneys were congested and of a dark color. The mucous lining of the bladder also exhibited marked hyperæmic changes. The vessels were decidedly injected in seven cases; there was a bright, uniform redness over the whole mucosa in three other instances. In one case only had the vesical lining a normal appearance. The cerebral vessels were filled with blood in eleven instances.

I exactly agree with Ströhmberg that the pulmonary oedema, the peculiar condition of the blood, the congestion of the brain and mucosa of the bladder, the post mortem appearance of the skin and the isolated areas of injection in the stomach altogether furnish a characteristic picture of the post mortem lesions of wood alcohol poisoning.

The treatment pursued was quite similar to that administered in America and with about the same results. If given very early it is occasionally helpful and may save life; generally it is of little use, sometimes because assistance arrives too late, more often because of the rapid absorption of the poison in overpowering quantities. The first aid is to wash out the stomach. Next in importance is the relief of the pulmonary oedema and retrobulbar neuritis by diaphoretics and hot applications to the extremities. Subcutaneous injections of pilocarpine and sweat baths are often useful and should be employed in most cases.

The symptoms and course of the blindness (already well known to us in America) are also well described by Ströhmberg in connection with the three cases of amaurosis among the survivors of the Dorpat debauch, and it is not necessary to repeat them here.

Since the publication of the investigations of

this subject by Buller and myself^a a number of methyl alcohol poisoning cases in America have come to light, some of which, for various reasons, deserve special mention.

CASE I.—*Poisoning from drinking methylated spirits. Recovery.*

Dr. Fred S. Spearman, of Whiting, Iowa, writes me as follows: "While a medical student at McGill College, Montreal, in 1903, I was working in a drug store. At that time the following case came under my observation: A. U., French Canadian, aged about twenty-six years, heavy drinker. He came into the store and asked for 6 ounces of methylated spirits to rub on sores on his legs. Knowing his habits I cautioned him strongly against drinking any of the spirits, telling him it was very poisonous. He afterwards acknowledged to me, however, that he had disobeyed; he drank nearly the whole quantity and was very sick for five or six days, but did not call a doctor. The symptoms were vomiting, severe abdominal pains with diarrhoea and great prostration. He said nothing about any eye symptoms."

The British methylated spirit (which contains ten per cent. of impure wood alcohol, two per cent. of mineral oil, and sixty-four per cent. of absolute ethyl alcohol) is a mixture so offensive to smell and taste that it is rarely used as a beverage. In a contribution to the *London State Journal of Medicine* (Volume X, 1902), J. C. McWalter claims to have discovered an increasing tendency on the part of the spirit drinking public to employ it internally. He estimates that there are in Great Britain 10,000 retailers of the mixture which is used, like our "Columbian spirits" and other forms of "deodorized alcohol," as a fuel, for stiffening hats, making varnishes, etc., to the amount of three and one half millions of gallons annually. McWalter's observations tally with the experience of the patient whose case has just been related. When driven to desperation for a drink some chronic drunkard might swallow a dose or two, but he could not take enough to kill or blind him. At least there has never been recorded a single instance of death or amaurosis from methylated spirits. Why cannot we also have (like the British and Germans) a cheap, untaxed ethyl alcohol mixture, so compounded that it will answer all the demands of commerce and yet not expose the public to such serious dangers as does the sale of our "deodorized" wood alcohol?

CASE II.—*Blindness from taking, according to directions, a patent medicine adulterated with wood alcohol.*

Dr. H. J. Hornbogen, of Marquette, Mich.,

^a Frank Buller and Casee A. Wood. Poisoning by Wood Alcohol. *Journal of the Am. Med. Association*, October 1-29, 1904.

reports: "On June 9, 1902, Theo. H., aged forty-two years, cook in a lumber camp, applied for treatment. A week previously, having contracted a severe cold, he began treating himself with Hinkley's bone liniment. He took, as directed on the label, teaspoonful doses in the form of a hot drink every hour or two. In the afternoon of the second day, having exhausted the contents of two bottles, he noticed a failure of vision, so that on the morning of the third day he had complete loss of sight in both eyes. The camp being located some distance from a railroad he was unable to get proper medical attendance until the seventh day.

"Upon examination I found the patient well nourished and in perfect physical condition, with the exception of total loss of vision in both eyes; he had not the slightest perception of light and the pupils were dilated to the fullest extent. An ophthalmoscopic examination showed the retina normal; disc white and slightly excavated. Patient was put on increasing doses of strychnine. Improvement was at first slow. In one month's time, however, V. O. D. = $\frac{15}{200}$; V. O. S. = perception of light. The patient returned to work for two weeks. Two weeks later the V. O. D. had again fallen to $\frac{15}{200}$; V. O. S. same as before. I have examined the patient several times during the past two years. He has a central scotoma. At the last examination his right eye had V. = $\frac{15}{200}$. With his left eye he can discern light only. I am reliably informed that in many of the lumber camp stores Hinkley's Bone Liniment is as much a staple as tobacco and that many of the woodsmen drink it in place of whiskey."

This report furnishes an excellent description of the typical amaurosis following wood alcohol intoxication from adulterated patent medicines. In the early onset of the symptoms and the almost complete and permanent blindness it closely resembles the Dorpat cases.

CASE III.—*Death from the secret use of "deodorized" wood alcohol as a beverage by a man unaware of its poisonous qualities.*

Reported by Dr. R. A. Walker and Dr. Calvin R. Elwood, Menominee, Mich. A. B., a man of good social position and supposed excellent habits, had acted strangely during the day and retired to his room. The suspicions of his landlady were aroused and a few hours later entrance was forced. He was found unconscious, and Dr. Walker was called. Patient did not recover from his coma and died a few hours later. No post mortem examination was made, except of the urine, which contained a large amount of albumin. His breath had a strong odor of wood alcohol and in his room was found an empty pint bottle (unlabeled), with a similar odor. The bottle was identified by a druggist as the one in which he had sold the victim wood alcohol the day before and which he had so labeled. He had also sold the man wood alcohol on previous occasions, without in the least suspecting his intention to take it internally. There is every reason to believe that the patient was unaware of the deadly

character of the alcohol; it is surmised that, until the day of his death, he had contented himself with merely taking "nips" from the bottle. At last he took an unusual quantity and, becoming unconscious, died before assistance could reach him.

CASES IV, V, and VI.—*Debauch of three men with a wood alcohol mixture. One death, one case of blindness, one recovery.*

Reported by Dr. H. S. Miles, of Bridgeport, Conn.

During the afternoon and evening of September 18, 1904, three men employed in a livery stable drank from a keg containing a remedy made with witch hazel two thirds and wood alcohol one third. This mixture was used as a liniment for rubbing on the horses. James M., who drank the most (an unknown quantity), became unconscious during the following night and died the next day with all the usual symptoms of methyl alcohol poisoning.

Robert N. says he imbibed "three big schooners, probably more." He suffered from pains in the abdomen, vomiting, and great thirst and was brought to the Bridgeport Hospital in a semi-conscious condition. His pupils were widely dilated, and (when aroused) he was found to be almost blind, being able to count fingers a few inches only in front of his face. On the first day his temperature was 96° F.; respiration, 26, and pulse, 94 to 116. He was given strychnine and pilocarpine injections. On the second day his sight was further reduced to perception of light in either eye. The ophthalmoscope showed some haziness along the margins of both nerve heads, but their color was not much changed. The arteries were small, but the veins were about of normal size. This patient slowly recovered. In a week the vision in his right eye was finger counting at one foot; in the left eye, fingers at six inches. Four weeks after the spree there was a further improvement. V. D. = fingers at ten feet; field good. V. S. = fingers at four feet; field not accurately measured, but found to be defective. At this date there were decided changes in the ocular fundi; the nerve heads were white, the retinal veins and arteries being both small.

The third member of the party, Frank W., had taken "only three drinks," which were followed by pain in the abdomen and vomiting, but his general condition, at the time, was not serious. His vision was $\frac{20}{40}$ in either eye, but as he said his sight had not been good before the drinking of the liniment, he was discharged without further examination.

The wood alcohol of commerce has undergone a complete change of character in recent years. Before 1896 it was variously known as wood spirit, wood naphtha, methylated spirit, pyroligneous spirit, etc., and found in the market as a vile smelling, greenish liquid possessing a disagreeable, burning taste. It was then, as now, employed for burning in spirit lamps, for polishing brass, dissolving gum in the manufacture of varnishes, for stiffening hats, for veterinary liniments, and for other useful purposes. Its powerful odor and nauseous taste prevented anyone

from drinking it or for substituting it for grain alcohol. In recent years, however, it has appeared under new names, and a more attractive guise. Deodorized and deprived of its disagreeable taste it has been put on the market in new forms and highly recommended as a suitable alcohol for "bathing and sponging the sick; making liniments; rubbing for rheumatism, etc." Columbian spirits is now employed in enormous quantities not only for legitimate purposes, but as an adulterant in numerous mixtures supposed to be made with pure ethyl alcohol. The more attractive varieties of "deodorized" wood spirit can with difficulty be distinguished from grain alcohol, having the same agreeable, vinous odor, warm taste, and some of the intoxicating qualities of the ethylic spirit for which it is so often substituted. When employed as we know it has been and is now used, to adulterate whiskey, "high balls," "punch," "hot drops," "witch hazel," "bay rum," eau de cologne, Florida water, essences of all kinds, Jamaica ginger, "extract of lemon," and the various "liniments," patent medicines, proprietary and domestic remedies, its taste is so disguised that it readily passes for the genuine article. Moreover, its solvent and intoxicating qualities are not inferior to those exhibited by grain alcohol.

Wood alcohol also appears in the retail market under other fanciful names. In the United States are on sale in many drug stores and other shops colonial spirits, union spirits, eagle spirits, and lion d'or; in Canada, green wood spirits and standard wood spirits; all being nothing more or less than "deodorized" or "purified" wood alcohol. The following quotation from a trade circular issued by a refinery of wood spirit in Boston, Mass., gives an idea of the commercial qualities claimed by the makers of the "deodorized" product:

"Lion d'or is a 98 per cent. pure methyl alcohol, the remaining two per cent. being water. It is a methyl alcohol of exceptional and remarkable purity, manufactured on a commercial scale as a substitute for the best quality grain alcohol, or cologne spirits, as used externally in the arts and manufactures. Lion d'or is readily miscible in all proportions with water, chloroform, ether, glycerin, and, in fact, in this respect is identical in behavior with the best known varieties of alcohol. Unlike other alcohols, lion d'or undergoes no deteriorating change with time, but after standing for years, will invariably open as pure and sweet as when first made.

"Lion d'or is clear and limpid, of purest water whiteness, and such odor as it may possess may be described as faintly spirituous; the sweet, sickening odor of the grain alcohol of commerce, and the empyreumatic and tar-like odors of wood alcohol are quite lacking. This almost total absence of odor constitutes, we may say, the most conclusive proof of the purity of our product. Lion d'or may be, and is being, used in the preparation of the finest perfumes, and the most delicate scents are brought out to an advantage hardly possible even with the use of the best French spirits."

Although the recent wholesale poisoning in New York city has drawn the attention of the public to the occasional employment of "deodorized" wood alcohol as an adulterant of whiskey, it is only fair to say that the practice of substituting methyl for grain alcohol for this purpose is not nearly as widespread as we have been led to believe. If it were, half the spirit drinking population would be dead or blind! Dr. Warren, pure food commissioner of Pennsylvania, who reported that "to February 5, 1904, he had collected and examined 1,000 samples of cheap whiskey from all parts of the State and found in over 95 per cent. of them varying quantities (some as high as 75 per cent.) of wood alcohol," has since admitted that the use of wood alcohol is less common than he at first suspected. In Chicago a well known publicist, influenced by the Stryker Farms tragedy, collected twenty samples of cheap whiskey from an equal number of low saloons. Not a single sample contained wood alcohol. According to a report made November 1, 1904, by District Chemist Hird to the health officer, there is no whiskey on sale in the bar rooms of Washington containing wood alcohol. The inspectors of the department picked up a dozen samples of whiskey in bar rooms where it was thought wood alcohol in whiskey was most likely to be found. Professor Hird's analysis revealed no trace of wood alcohol in any of the samples. Truths about the adulteration of food and drink in the United States are startling enough without exaggerating them.

Although it is probable that, for a time at least, the "nine days' wonder" of the wholesale poisoning in New York city will act as a deterrent and, perhaps, for a time entirely prevent the adulteration of whiskey with wood alcohol, it is doubtful whether it will have much effect, either now or hereafter, upon the substitution of Columbian spirits for ethyl alcohol in the manufacture of patent medicines, perfumes, condiments, essences, and flavoring extracts which are widely consumed for the alcohol they contain. Death and blindness from these sources usually occur in isolated instances only and are not frequent enough to arouse public interest in the dangers of poisoning from this sort of adulteration.

Poisoning by Inhalation.—The statement that blindness may be produced by the absorption of wood alcohol fumes is controverted by some. They assert that in hat and whip factories, where the employees are constantly exposed to the fumes of wood spirit and where the air is laden with the evaporated poison, no cases of blindness occur. A physician residing in a factory town

where wood alcohol is largely used writes me, "It is a well known fact among the employees in the filling rooms of our factories that many of the men, especially green hands, are affected with giddiness and act and talk as if intoxicated after working in these rooms. This intoxication, however, they attribute to the fumes of turpentine, benzine, and allied liquids that are largely used in these rooms. I believe the symptoms to be due to the fumes of wood alcohol and mean to investigate the subject a bit. I have just called up on the telephone the superintendent of one of our largest factories, who states that the poisonous character of wood alcohol is well known among the employees, that they had a very practical demonstration of it some years ago in the death of several men who drank it." It is only proper to reiterate that the breathing of wood alcohol fumes diluted with a sufficient quantity of pure air (as in any well regulated, properly ventilated factory) is not dangerous to the eyesight, although I should not, without further investigation, regard work in a wood alcohol, hat, whip, or varnish factory as a healthy occupation. It is work carried on in a confined space filled with re-breathed air and wood alcohol fumes that constitutes the dangerous occupation. The varnishing of closed beer vats, closets, or small rooms with the windows and doors closed, or the burning and evaporation of wood spirit in a confined space that has been responsible for a number of published and well authenticated cases of blindness.

The total number of cases of blindness and death from this poison continues to increase. Buller and I were able to report 153 instances of blindness and at least 122 cases of death. To the list of blind victims we must now add the three cases reported by Ströhmberg and the two histories given here. To the roll of deaths are to be added the 15 cases of death in Dorpat, the 17 deaths in New York, and the two hitherto unreported instances given in this article. Thus, we have 158 authentic cases of blindness and 156 deaths; in all, 314 serious examples of methyl intoxication. There is every reason to believe that if the whole truth were known these figures would be largely increased and the full number would exceed 400.

The Eye Signs of Wood Alcohol Intoxication.—Whenever a patient shows decided symptoms of alcohol intoxication, abdominal distress and weakness of the extremities, followed by sudden blindness in both eyes, the presumption is that he has imbibed some methylated preparation. However blind he may become, sight almost always improves after a few days, to relapse, once more into permanent blindness. The visual fields are con-

tracted and present absolute central scotomata. In the fundus oculi are seen at first a congested nerve head with injected vessels; later, grayish white (secondary) atrophy and contracted vessels. These signs, generally accompanied not only by blindness, but by redness of the eye ball, pain in the globes, tenderness on pressure over the lids, discomfort on looking about, slight photophobia, and dilatation of the pupils correspond in the first stage to an acute retrobulbar optic neuritis. When the early inflammation and swelling of the nerve subside, vision for a time improves but the damage to the nervous tissues shortly terminates in a postneuritic atrophy with eventual permanent blindness.

Prevention of Wood Alcohol Poisoning.—The section in ophthalmology and the house of delegates of the American Medical Association this year passed a unanimous resolution calling upon the various State and Federal authorities to have all wood alcohol preparations placed on the list of poisons. To their credit also, be it said, the Wood Products Company, of Buffalo, N. Y., makers of 95 per cent. of the deodorized wood alcohol consumed in and exported from this country, are doing all in their power to prevent poisoning from their Columbian spirits and other wood alcohol goods. My colleague, Dr. Frank Buller, has suggested that every package, wholesale and retail, of wood alcohol, of the "deodorized" article in particular, should bear the warning, "this fluid, taken internally, is likely to produce blindness." Such a label might be even more effective than the legend "Poison" and the familiar picture of the skull and cross bones, chiefly because to most people the fear of blindness is more impressive than that of possible death.

No doubt this precaution would limit the dangers of serious poisoning from methylated preparations, but it is very doubtful whether it will be entirely effective. As stated elsewhere, whenever a government permits the sale of deodorized wood alcohol (as in the case of Columbian spirits in the United States and of standard wood spirits in Canada) the only effective safeguards (the offensive odor and taste) against ingestion of the poison is removed and the annual sacrifice to death and blindness will certainly continue. Either the manufacture and sale of "deodorized" or "purified" wood alcohol should be absolutely prohibited or, as in *Germany and Great Britain*, an untaxed ethyl alcohol, or one rendered undrinkable by the addition of mineral oil, wood spirit, naphthalin, or some other nauseous compound, or both, should be allowed for use in the

arts in the place of Columbian spirits and similar dangerous preparations.

The fact that the annual consumption of millions of gallons of cheap alcohol in other countries has been going on for years without fatal consequences, while in America we have had hundreds of deaths and cases of blindness from the employment of an agent that possesses no advantages over methylated spirits, or *Brennspritus*, is surely an unanswerable argument in favor of this proposal.

THE TREATMENT FOLLOWING THE BLOODLESS REDUCTION OF CONGENITAL HIP DISLOCATION.

FOURTH ARTICLE.

By DEXTER D. ASHLEY, M. D.,

NEW YORK,

ATTENDING ORTHOPÆDIC SURGEON, ST. MARK'S HOSPITAL;
CHIEF SURGEON, ORTHOPÆDIC DEPARTMENT,
GERMAN POLIKLINIK,

AND

FREDERICH MUELLER, M. D.,

CHICAGO,

PROFESSOR OF ORTHOPÆDIC SURGERY, MILWAUKEE; ATTENDING
ORTHOPÆDIC SURGEON, ST. LUKE'S HOSPITAL, CHICAGO.

A short space will be devoted to a discussion of the paralyses which sometimes follow the bloodless reposition of congenital hip dislocation. The phenomena of paralysis appear in the fields of both the large nerves supplying the lower extremities.

The paralyses appearing in the field of the sciatic nerve are very important in a clinical and practical sense, as they form rather a serious complication. These paralyses are analogous in ætiology and clinical appearance with those which appear after the open operation for reposition. It is, therefore, permissible to apply the experience acquired in dealing with the paralyses observed in the open operation, to those appearing after bloodless repositions.

In order to overcome the shortening of the limb in the open operation, traction is applied immediately after the incision is made into the muscle and the capsule. The reposition of the dislocated femoral head and the application of the cast in a moderately abducted position are the next steps. It is apparent that the sciatic and crural nerves must be stretched in proportion to the extent of the previous, existing shortening. If the shortening has been considerable and the resistance great, it is not unusual to observe paralysis of the entire limb, both nerves being injured. As a rule the crural nerve proves to have received the less dam-

age. In a majority of cases only motility is lost, sensibility remaining intact. The least serious cases are characterized by the paralysis of the long and short peroneal muscles only. The next degree of paralysis involves the deep branch of the peroneus nerve also, which injury results in a consequent elimination of the sensibility of the foot, and a loss of motility in the tibialis anticus and the extensors of the toes. In a more serious degree of paralysis there appears an additional loss of motion in the muscles of the calf. In other degrees, motor and sensory paralysis of the entire lower leg is accompanied by motor paralysis of the biceps, semitendinosus and semimembranosus. Very often the quadriceps muscle is involved, and the most severe degree may be characterized by a total motor and sensory paralysis of the limb.

If the sensibility is involved, neuralgias appear some time after the trauma, and develop to hyperæsthesia, the toes especially becoming very sensitive even to the slightest touch. These conditions are characteristic when following a severe paralysis.

The diagnosis of injury in the sciatic field is very easily made from the loss of motility in those muscles which are supplied by the peroneal nerve, which is noticeable in every case where an injury of the sciatic nerve has been sustained.

The prognosis of an injury to the sciatic nerve is not a favorable one throughout. The sensibility, as a rule, returns, except in a few longitudinal strips, and a similar but only partial recovery is observed in the motor branches, the locations especially predisposed to permanent paralysis being the peroneus longus and brevis, and the muscles supplied by the deep peroneal branch. In all cases of motor paralysis in the peroneal muscles, abnormal positions of the foot will be formed, due to disturbance of the equilibrium of the musculature. These deformities are chiefly pes equinus and equinovarus.

The question arises why, among all the sciatic branches, the peroneal nerve is the greatest sufferer through paralysis. This is doubtless to be attributed to the more serious damage inflicted upon this nerve. This may be explained by its topographical course. After the sciatic nerve leaves the great sciatic notch, it runs between the extensors of the femur and the flexors of the knee, embedded loosely and very movable. At the lower third of the femur it branches, the larger branch forming the internal popliteal, and the smaller branch the external popliteal or peroneal nerve. The main trunk of the nerve, as the internal popliteal, continues loosely embedded be-

tween the muscles, and may be traced down through the popliteal space into the planta pedis. The peroneal branch proceeds outward through the popliteal space, attaching itself to the long head of the biceps, and is thus conducted to the head of the fibula. In the region of the head of the fibula the peroneal nerve forms a connection with the peroneal capsule by means of fibres which run into a funnel shaped canal from the capsule to the sheath of the nerve. This arrangement may be demonstrated if we dissect out the peroneal nerve above and below its entrance into the capsule, and then apply tension above and below. From these anatomical conditions, it is evident that the stretching force is unequally distributed, there being a fixed point in the peroneal capsule, while on account of the loose embedding of the sciatic trunk, the same force is distributed over a length twice as great as that of the peroneus. If the stretching force is applied rapidly, the danger of tearing the nerve at this fixed point is greatly enhanced.

The duration of the paralysis of the peroneal nerve is quite protracted. In severe cases there may be two or three months of the neuralgic stage, followed by four to eight months of the stage of flabby paralysis, after which there is a period of gradual restitution of motility, which is quite often not complete.

As to the therapy, we use during the neuralgic stage a weak descending galvanic current of from one to three milliamperes. This is applied to good advantage for several minutes in the form of the electric bath. Effleurage, if it is possible to administer it, is sometimes beneficial.

During the stage of flabby paralysis, faradization and galvanism may be successfully used. The constant currents are of medium intensity, three to six milliamperes, and the points of application must be repeatedly changed during the administration.

It is expedient to put on the patient, for his walking exercise, a movable splint, including the calf and foot. This splint furnishes a certain support for the knee, preventing the formation of pes equinus, and protecting the over sensitive foot from mechanical injury. In severe cases it may be advisable to include the entire leg and foot in plaster of paris until the neuralgic stage subsides.

Another cause for paralysis of the peroneal nerve is pressure, sometimes occurring during manipulations in extreme abduction, and due probably to the pinching of the nerve between the femoral head and the pelvis. With unskilled operators this is a frequent cause for this paraly-

sis, which is likely to affect both the internal and external popliteal branches. The clinical symptomatology and therapy are the same as already given.

A specific paralysis peculiar to the bloodless reposition is represented by the isolated motor paralysis of the crural nerve. Its origin is not so apparent as the paralysis of the sciatic nerve. The prognosis, however, is decidedly favorable, as this paralysis uniformly subsides after a duration of from three to eight months. As a rule restitution takes place under the first cast. Although it is true that this paralysis is generally observed after a difficult reposition, still it does not seem to be due to the direct stretching force. The probability is that the nerve is squeezed either against the pubic bone or the femoral head, or that it is compressed by the fascia, which is put under great tension because of the position of over extension.

It is unnecessary to deal extensively with the isolated quadriceps paralysis, as it gives no cause for apprehension. It is, however, necessary in these cases especially, to lay great stress upon the regular, passive, extreme extension of the knee, because of the threatening possibility of a contraction of the knee.

CONSERVATIVE TREATMENT OF AFFECTIONS OF THE UTERINE ANNEXA. ITS INDICATIONS AND LIMITATIONS.*

By GEORGE TUCKER HARRISON, M. A., M. D., Etc.,

NEW YORK,

HONORARY FELLOW OF THE MEDICAL SOCIETY OF VIRGINIA,
SURGEON TO ST. ELIZABETH'S HOSPITAL, ETC., ETC.

The development of modern surgical therapeutics is undoubtedly in the direction of conservatism. Says Tillmanns in the last edition of his work on general surgery: "The antiseptic and aseptic method has expanded our operative activity in a way never dreamed of, but has at the same time promoted the conservative direction of our therapeutics; more and more do we succeed in avoiding mutilating operations." Speaking of the surgery of the future, the writer declares his belief that its endeavor will be to heal diseases without the knife, that have been hitherto incurable, and especially general toxæmic conditions of the body produced by bacteria. Gynæcological surgery has felt the influence of the spirit of late years, and thereby its scientific standing has been largely augmented. In his excellent work on operative gynæcology, Howard Kelly expresses himself in most positive terms in favor of con-

servatism, in the diseases under discussion, and enters into an elaborate argument to prove the correctness of his position. This chapter is well worthy of careful study by all interested. Listen to the language used by the late William R. Pryor, whose premature death was so great a loss to science: "It is but a few years ago that for the most trivial reasons the ovaries were sacrificed. The unthinking and rash way in which those who posed as specialists in the diseases of women operated upon and removed organs which did not conform to some ideal in structure which the operator had adopted, very justly brought the specialty of gynæcology into disrepute. A better knowledge of the physiology and of the pathology of diseases peculiar to women has brought about a most radical change in our views regarding the propriety of removing the ovaries and tubes."

Prophylaxis demands that the principles of asepsis should be carried out in the conduct of every birth and in all operative procedures. Its main problem, however, is to prevent the ascent of gonococci in fresh cases of gonorrhœa in women. All intrauterine manipulations should, in these circumstances, be strictly interdicted, nor should the patient be allowed to use vaginal douches, as thereby the ascent of the infection might be favored. The husband should be taught the evil results of recrudescences of the gonorrhœal infection and the danger of extending the inflammation in consequence of sexual intercourse. While he is undergoing a cure, the wife should have absolute rest, so far as her sexual life is concerned and thus the infection may be limited to the cervix. In affection of the tubes even the slightest operation upon the genital organs may be attended with danger. The treatment of salpingitis, or salpingoophoritis necessarily varies according to the stage of the disease in which intervention comes into play. During the development of the acute phenomena two cardinal principles must guide our treatment; absolute corporeal and sexual rest. If an ice bag is placed over the hypogastrium and, if necessary, the liquor opii compositus given internally or the aqueous extract of opium per rectum, even the worst external forms of gonorrhœal peritonitis will run a favorable course.

Another method of treatment found an enthusiastic advocate in the late Dr. Pryor, and I cannot commend it too highly. The underlying thought of the method is the prevention of the destructive effects of the infection, by a conservative operative procedure. The patient being placed in the lithotomy position, a thorough curettage is made, taking care that the operation is a

* Read before the Virginia State Medical Society at its thirty-fifth annual meeting.

thoroughly aseptic one. The object of the curettage is to cut off the main source of infection. Douglas's cul de sac is now opened, serum and lymph making their escape through the opening. The index finger is carried into the cavity behind the uterus and a thorough exploration made. The tubes and ovaries are freed from the investing lymph and all adhesions loosened. The tubes may be brought to the vaginal opening for inspection. A probe passed through the fimbriated extremity assures us that it is patulous. A piece of iodoform gauze may be passed into the tube, during the manipulation, as suggested by Pryor. After the ovaries and tubes are freed from all adhesions, the gauze pads, which had been inserted to keep the intestines out of the way, are removed and the pelvis is carefully dried, the gauze being removed from the tubes. It may here be observed that for these manipulations in the cul de sac, the operator will be greatly facilitated in his task if the patient is in the Trendelenberg position, at an angle of 45°. The uterus is now packed tight with iodoform gauze. I use by preference the gauze prepared according to Pryor's formula, as I have never seen a case of iodoform poisoning follow its use. It fulfils three indications; it checks bleeding, it absorbs discharges, and maintains the parts in an aseptic condition. Strips of iodoform gauze are carefully inserted into the opening into the posterior cul de sac, filling it and extending as high as the internal os. The uterus is now restored to its normal position and the vagina packed with gauze. After the expiration of two days the vaginal and uterine dressings are removed and substituted simply by a vaginal. The packing in the cul de sac remains in place for a week. Another dressing is then introduced, which remains untouched for about five days before being renewed. The great advantage of the operation is that it prevents suppuration and leads to permanent cure.

In chronic cases the *weight* therapeutical method has been used with such a marked degree of success as to warrant adoption into practice. The vagina is first of all thoroughly disinfected. A colpeurynter is then introduced. In filling it care is taken to cause no pain; in order to accomplish this, the tube of the colpeurynter is drawn over the neck of the flask containing the quicksilver. The flask is now elevated and the quicksilver is allowed to run into the colpeurynter. As soon as the patient feels pain the operator stops or even allows some of the quicksilver to return, 500 to 1,000 grammes sufficing. The foot of the bed is elevated about twelve inches, so that the weight of the quicksilver acts upon the pelvic

roof. A portion of the contents is again allowed to run off. A bag of shot is spread over the abdomen, extending from the symphysis to the umbilicus. Instead of the colpeurynter a condom containing shot may be used. This treatment may continue day and night. An application of the treatment for three or four hours each day is also productive of good results. The symptoms show soon a marked improvement. At times, however, fever comes on and may be high. This indicates the presence of pus and the continuance of the treatment is contraindicated.

In cases of accumulation of pus in the pelvic cavity, whether in the tubes or involving tube ovaries and peritonæum, the vaginal incision of the pus sacs is indicated in a large number of cases, and especially is this true in the case of young women. The surpassing virtue of the conservative method of treatment is that if circumstances subsequently demand it the radical operation may ensue as the *ultima ratio*. The objection has been raised that by this method the majority of cases of pyosalpinx are insusceptible to cure. J. Veit remarks on this point as follows: "The technique of the opening is in itself not difficult, but the drainage and the irrigation of the opened part of the tube do not act on the entire pyosalpinx. Particular sections, on account of the flexed course, may lie so unfavorably that healing is out of the question. In this way originates the picture of the perforated pyosalpinx with all its horrors." This experience, however, is exceptional and should not deter from the performance of the operation, which is eminently successful in the larger proportion of cases, if properly performed. If we succeed in evacuating the pus, which is found in or around the tubes, in a thorough manner, and provision is made for satisfactory drainage, the ovary and tube may be allowed to remain; they will heal like any other abscess wound.

The method of operation is as follows: The patient is placed in the lithotomy position and an anæsthetic exhibited. The uterus is dilated and a curettage performed, a piece of iodoform gauze is passed into the uterine cavity and then withdrawn; this may be done a second time for the purpose of cleansing the endometrium and removing all débris. The cervix is seized with a bullet or traction forceps, while an incision is made through the vagina close to and behind the uterus. The uterus is more or less fixed by adhesions and of course cannot be pulled down as under ordinary circumstances, consequently the peritonæum seems to be high up. The best way of gaining entrance into the peritoneal cavity is by the index

finger. After its introduction into Douglas's pouch, the finger explores the posterior face of the uterus and then passes on each side behind the broad ligament. Some portion of tissue will perhaps be found softer than the remainder and by a little effort a pus cavity is opened. Sometimes the tissue is too tough to be broken into by the finger, and a pair of closed scissors, not too sharp at the points, will open the way. By combined manipulation, a hand on the abdominal wall cooperating with the finger within, we ascertain whether there is a single pus cavity or whether there are several, and in more or less proximity. An effort should be made to break up the partition wall between the respective pus cavities, so as to unite them in one. Irrigation should not be used, as there might be danger of forcing the fluid through the roof above formed by adherent organs and so carrying infection into the general peritoneal cavity. During the entire operation it is of paramount importance, by combined manipulation, to ascertain the exact situation of the inner exploring finger and whether pockets of pus still exist unopened. The cavities are then packed carefully with iodoform gauze. The dressings are renewed as often as necessary.

Pryor believed that in cases of sepsis the iodine was the effective agent in combating the disease by its absorption, when employed as described. It now appears, according to the most recent researches of Heile (1903), as quoted by Lexer, *Lehrbuch der Allgemeinen Chirurgie*, that the iodine becoming free is not the most important substance, and that under certain circumstances a strong antiseptic effect appertains to the iodoform. The effective body is probably diiodoacetylde, which, however, is only formed under exclusion of oxygen, consequently in deep cavities, in the decomposition of iodoform by reduction. The toxicity of this substance is responsible for the phenomena of iodoform poisoning. On the contrary, when iodoform decomposes with free access of air, the poisonous products of decomposition are transformed into non-poisonous ones by oxygen, according to Heile, which explains the fact that in superficial wounds a bactericidal effect is not produced.

In spite of the fact that inflamed organs are left behind, and that only the product of inflammation, the pus, is removed, a good result may be expected, if thorough drainage is carried out, and the treatment is further aided by weight on the abdomen. In a large proportion of cases just as much, nay more, is accomplished than by the removal of the entire internal genital organs. A hydrosalpinx is usually amenable to conservative

treatment. It may often be treated by vaginal incision and posterior colpotomy. The tube is freed from adhesions and drawn into the vagina, an incision is made and loose tissue trimmed off. A piece of iodoform gauze is then inserted and the vagina packed with the same gauze. In hydrosalpinx, when the tube is closed, salpingostomy is indicated. The operation, of course has, as a postulate, that the perisalpingitis process has come to an end and that the contents of the tube are not purulent, otherwise the salpingostomy might cause the death of the patient in consequence of septic peritonitis. It is well to bear in mind the warning given by Veit, vide *Handbuch der Gynäkologie*, Bd. III S. 819: "If we find in a sterile woman occlusion of the tube or salpingitis," he remarks, "local therapeutics of any sort of serious nature should not be undertaken in such a case, until we are quite sure that the husband is quite sound." Salpingostomy, he believes, would be justified only when the physician has found living spermatozoa in the husband.

The most difficult problem in the direction of conservative therapeutics is furnished by gonorrhœal pyosalpinx. Our efforts at conservatism in such cases may here prove fallacious and the patient after a short period of improvement may have a recrudescence, to be followed by all the old pains and annoyances. After a continuance of the disease for some time, there is a reaction on the general health. The constant pains lead to hysteria, lack of exercise in the open air and pains in defecation lead to constipation, thence follow loss of appetite, dyspepsia, insufficient amount of daily food being taken, until the clinical picture presented is a combination of emaciation, anæmia, nervous irritability, and cachexia. The patient consults one physician after another and finds that all her efforts to regain her lost health are in vain. If such a woman has to work for her living, and so many of them have to do that now under the conditions of our modern civilization, it is no wonder that she embraces with pleasure the opportunity of being relieved of all her woes and restored to health by a radical operation, especially if the operator holds out hope of certain cure. In some cases the hope is fully realized, and by the radical operation of removal of the annexa, with or without the extirpation of the uterus, the patient is awakened to a new life. But in others this is not true, the phenomena called forth by the forcible anticipation of the menopause being so distressing as to make many a woman declare that her condition is much worse after than before the operation. Internal pains, due to exudation about the stump,

may also make life miserable. Before a radical operation is advised, the gynecological surgeon should let his patient know that she purchases her restoration to health at the expense of the loss of her internal genitalia, the faculty of generation, and libido. In cases of double gonorrhoeal salpinx, however, the possibility of impregnation is lost, in any event.

It having been decided that a radical operation is indicated, a number of questions present themselves which have been answered differently by different operators. The first relates to the route, whether by vaginal or abdominal incision. For my own part I prefer the abdominal way, as then we gain a better view of the tube sacs, the nature and extent of the intestinal adhesions, the topographical relations of the inflammatory products, and, lastly, are much better able to control hæmorrhage. The technical difficulty in the way of ligating the ovarian arteries per vaginam being sometimes invincible.

Another question relates to the advisability of leaving behind or removing the uterus, when tubes and ovaries are removed in cases of double pyosalpinx. At the meeting of the American Gynecological Society, in May, 1903, this subject was discussed by a number of gynecologists, the majority arguing in favor of total hysterectomy. Those who are interested will find their account in consulting Volume 28, *Transactions of the American Gynecological Society*. The best method, I believe, is not to remove the entire uterus, but to perform a supravaginal amputation, after the method of Fritch,¹ by a wedge shaped incision and then unite the cut surfaces, coronally, the peritonæum being drawn over the wound. It has been recommended to burn the cut surface of the cervix with the Paquelin thermocautery. Instead of this, I especially recommend the use of collargolum. After the removal of the annexa, the uterus loses its significance and often has the disturbing influence of a foreign body, standing in the way of perfect recovery. It is important, however, to retain the vault of the vagina, in its normal integrity, and this we do by this method of operation. It is all important whenever possible in the performance of the radical operation, to leave a portion of the ovary, knowing as we do the influence it exerts on the entire organism.

An excellent conservative operation has been suggested by A. Palmer Dudley² and Daederlein³ in these cases, in which the tubes are removed, and which consists in the implantation of an

ovary into the fundus of the uterus. This operation is especially indicated in young women, and is thus performed: An opening is made into the fundus uteri, large enough to admit two fingers, which opens the cavity of the uterine body, and into this opening the ovary is inserted and fastened by sutures, with the view of maintaining the function of the uterus and, possibly fertility. Daederlein has never known the operation to be followed by pregnancy, nor did it occur in Dudley's case.

In conclusion, I would say that the attitude of modern gynecology towards inflammatory affections of the annexa is eminently a conservative one. It recognizes the fact that in the majority of cases it is not the disease that threatens life, but rather the operative procedure. Radical operations, involving the removal of all the internal genital organs, are reserved for those cases in which life is jeopardized by a continuance of the disease.

63 WEST FIFTY-FIRST STREET.

Pennsylvania State Pharmaceutical Board.—

The following Philadelphians have passed the examinations of the Pennsylvania State Pharmaceutical Board, and are licensed as registered pharmacists or justified assistants:

Registered Pharmacists—Nellie J. Stevenson, William J. Shea, Samuel S. Newcomer, Clarke Gamble, Genaro Titomanlio, John G. Armstrong, Charles J. Hendler, Le Roy W. Kurtzman, Louis H. Hausmann, Jr., Arthur William Crawford, D. Morris Hassman, Louis Wagner, Otis L. Ulrich, Harry Eisenhardt, John Henry Gross, Louis Green, Virden P. Ashmead, Robert K. Pentland, Robert W. Shelton, Howard T. Jackson, Albert N. Humpton, Henry C. Long, Jr., Galeno A. Ciccone, Harry C. Bingham, Isadore Henry, Jacob D. Albright, Calvin M. Reigel, and Louis Baun. Justified Assistants—Robert R. Saunders, Samuel Goldberg, Samuel Feldman, Samuel Canter, William A. Rabb, William E. Gregory, Frank Eidam, Edwin W. Bray, Herbert E. Slough, Silvio Ciancareli, Emil Vogel, Frank G. Fogg, J. Bowman Metz, George Lewis Pfeiffer, George I. Olewiler, Louis Entine, Harvey P. Feigley, Joseph H. Feckula, Jay Fisk Smith, Clawson S. Coler, Raymond Sharp, Franklin L. Tallman, Charles W. Evans, George J. Crouse, George Ruby, Adolph Hopkin, Jayson A. Herr, William W. Witmer, Samuel Axilbund, Paul P. Robinson, Wilfred S. Thompson, Raymond J. Wolf, John D. Dawson, Gibert March, George Edward Paules, Harry M. Fahr, Fred R. Perry, Benjamin H. Jenkins, Ira G. Gasser, William W. Fester, Jr., Charles Mann, William A. Glenn, Thomas A. Doud, and Alexander F. W. Mackie.

In addition to Miss Nellie J. Stevenson, whose name appears on the above list, two other young women in Pennsylvania passed the examination for registered pharmacists, M. Margaretta Hodge, of Blairsville, and Merle E. Arnold, of Dillsburg.

Church Hill, Va., Medical Society.—The Church Hill Medical Society held its annual meeting on December 8th. Dr. Julian Oppenheimer was elected president; Dr. A. L. Leftwich, first vice-president; Dr. E. W. Gee, second vice-president; Dr. M. Benmosche, secretary, and Dr. George E. Barksdale, treasurer.

THE MANAGEMENT OF PNEUMONIA.*

By OLIVER T. OSBORNE, M. A., M. D.,

NEW HAVEN, CONN.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AT YALE UNIVERSITY; PRESIDENT OF THE AMERICAN THERAPEUTIC SOCIETY.

Pneumonia, second only in importance to tuberculosis, has begun to compete with the latter in claiming the attention of municipal boards of health. Certainly during the last ten years the number of reported deaths from pneumonia has greatly increased in most of our large cities. This reported increase, however, is not an absolute one, as with the ever advancing education of the people along insurance lines, many certificates are handed in for pneumonia which really should be for consumption. Also, many deaths of children are now reported as due to bronchopneumonia which were previously reported as deaths from bronchitis or capillary bronchitis, and statisticians compute bronchopneumonia with pneumonia.

However, the fact that pneumonia is the most fatal of all acute infections is my excuse for considering a subject which is so well understood. We can, perhaps, not have too frequent discussions of a disease that so many times baffles us all, hence in making a few suggestions I may be pardoned for reciting many well known truths.

In considering inflammation of the lung we should not forget that the latter has two distinct systems of circulation; that derived from the pulmonary arteries carrying venous blood to the air vesicles and returning the aerated blood through the pulmonary veins; and that coming through the bronchial arteries from the aorta carrying arterial blood and nutrition to the lung tissue; a weak right side of the heart impairing one circulation and a weak left side of the heart impairing the other. Also, a weak right ventricle will allow a profuse bloody or prune juice exudate and expectoration, while a weak left ventricle may be one cause of the lack of resolution in a pneumonic lung.

Pneumonia is due to an infection, and often causes a temperature out of all proportion to the amount of lung involved, or it may cause irritation of the brain out of all proportion to the local manifestations. The germ that causes this disease may migrate to different parts of the body and cause trouble in different parts, and such secondary infections are frequent.

Probably, ordinarily, only the toxins of the pneumococci enter the blood and cause the later

symptoms of toxæmia. If the pneumococci themselves enter the blood, various complications occur, such as empyema, perhaps from the extension of the infection, endocarditis, middle ear or mastoid inflammation, or a joint complication. The crisis of pneumonia may be due to the pneumococci themselves producing enough of their own toxins to inhibit their further growth, somewhat like the ferment of the tubercle bacilli, or it may be due to a sufficient amount of antitoxine formed in the blood to combat their growth or their toxins. In normal cases this occurs at the eighth, ninth, or tenth day. If such a crisis does not occur, it is probably because other fresh foci of pneumococci have started fresh toxins, or because the leucocytosis is not sufficient, or an antitoxine is not produced in sufficient amount. The toxine formed by the pneumococci seems to be a decided depressant to the heart, vying, perhaps, with the depressant action of the diphtheria bacilli.

Although there cannot be a real pneumonia without the *Micrococcus lanceolatus* of Fränkel or Sternberg, we recognize a streptococcus pneumonia, which is the variety that develops upon la grippe, or influenza. Traumatism does not produce true pneumonia.

The blood count in pneumonia is interesting and prognostic, a leucocytosis of the polymorphonuclear cells being always present, **except** in cases of bad prognosis. This leucocytosis varies in amount, but in ordinary severe cases it should be not far from 20,000 per cubic millimetre. A low white blood count either indicates a very mild infection or, more frequently, the inability of the system to react to the infection, and a persistently low blood count gives an unfavorable prognosis.

The principal danger in this disease lies in heart failure, and it is the right side of the heart that generally fails. This can sometimes be foretold by the accentuated closure of the valve at the pulmonary orifice suddenly becoming less pronounced. At this time fibrin seems to easily form in white clots, sticking to the chordæ tendineæ, to the wall of the heart, or to a valve, causing murmurs; such obstruction is often the final cause of cardiac failure. Also, a weakened right ventricle may cause enlargement of the liver, and even some jaundice from passive congestion, enlargement of the spleen, and an albuminuria.

The greater the consolidation, and the more lung tissue involved, the more difficult it is for the right ventricle to force blood through the pulmonary circulation. This causes an overfilled right ventricle and an under filled left ventricle,

* Read at the meeting of the Connecticut Medical Society, held in New Haven, May 25 and 26, 1904.

and often therefrom irregular contractions of the heart, and the dicrotic pulse, a dangerous symptom. The imperfect action of the right ventricle can cause the peculiar dusky hue of the countenance due to venous stasis, and except in collapse this is not due to lack of oxygen or lack of aeration of the blood, as the rapidity of respiration, nature's way of increasing oxygenation, is generally sufficient. This same venous disturbance is doubtless often the cause of the cerebral irritability, restlessness, wakefulness, and finally delirium which occur so frequently in pneumonia, and there may be even sufficient congestion in the brain to cause an extravasation of liquid into the ventricles without actual infection of the meninges.

Though it is doubted by some, I believe that pneumonia can start from the central part of the lung, the so called "sneaking," or central, pneumonia, and in the first stage give no positive physical signs. The symptoms which should cause such a pneumonia to be suspected are fever preceded by a chill, some cerebral congestion, flushing of the face, often herpes of the lips, and increased respiration.

We must also recognize the not infrequent occurrence of pain referred to the abdomen, even low down, from lung irritations. This occurs not infrequently in children with pleurisy and even with pneumonia, and can occur in the adult. Also, some of these abdominal pains and abdominal resistance are due to associated diaphragmatic irritation, which is a condition often ignored or overlooked. Hence in obscure abdominal signs, with fever, the lungs should be carefully interrogated.

Besides the interest which attaches to the microscopical and bacteriological investigations of the sputum, which will always give a clue to the character of the infection that we have to combat, it is interesting to note that the sputum contains a large amount of albumin and sodium chloride, which latter is probably the reason that the urine contains so few chlorides during the pneumonic process. This also gives an indication to supply sodium chloride and plenty of albumin with the food.

Deaths occurring during the second and third days of pneumonia are often not caused by a large amount of lung involved, but apparently by the intensity of the infection. This sort of toxic death is seen in malignant diphtheria, malignant scarlet fever, and malignant dysentery, and perhaps means, as I have elsewhere termed it, "medical shock," which is probably a toxæmia sufficient to prevent leucocytosis and to paralyze the supra-

renals and the vasomotor system. Deaths that occur later are generally from exhaustion, largely cardiac, and, except in double pneumonia, are not due to the amount of lung involved.

As to the prognosis of conditions, it may be stated that a very severe chill in the beginning shows that the infection is serious. When both lungs are involved, less than half the patients recover. A feeble or dicrotic pulse, or a pulse too high for the temperature, is a bad omen. A temperature of 105° is not particularly objectionable if short-lived, but above 105° there is progressively more danger. A concomitant bronchitis of the other lung is very undesirable, and of course œdema of the lungs is dire. Valvular lesions of the heart, kidney insufficiency, or an arteriosclerosis make the prognosis bad. Scanty expectoration in the second and third stages is often of bad omen.

The mortality varies with age, the lowest, about 10 per cent. or even less, being between the ages of twenty and thirty years, while the highest mortality is from 50 to 60 per cent., being in patients over fifty years old. Hospital cases do not do so well as private cases. This is natural, in view of the class of people that are taken to the hospitals on account of pneumonia, and also on account, generally, of the severity of their exposure.

We may premise any suggested therapy by the assertion that about 50 per cent. of patients with pneumonia will get well by good nursing, good nutrition, and proper hygienic surroundings. With the other 50 per cent. a great deal can be done and a great deal must be done by the physician, and except in about the above 50 per cent. pneumonia does not necessarily tend to recovery. However true it may be that twenty or more years ago pneumonia tended to recovery, since the last la grippe epidemic, which began ten years ago, pneumonia in at least 50 per cent. of cases does not tend to recovery.

Although we have no specific treatment for pneumonia and cannot shorten its process or fight the pneumococci as such, as is so well said by Pell, of Amsterdam, it would be a poor captain who left his ship to its fate because he was not able to subdue the gale. It was just his high duty, which must not be underrated, to steer the ship clear of breakers and cliffs safe into the sheltering port. Therefore the management of pneumonia was of great importance.

A word as to prophylaxis. While we have been turning our attention toward the prevention of tuberculosis, and promoting sanatoria for the treatment of that disease, pneumonia has been in-

creasing its ravages. Doubtless the pneumococcus is wafted about in the dust as is the tubercle bacillus, and as a matter of fact pneumococci are many times found in the mucus of the mouth and throat, although they probably never cause pneumonia unless they reach the minute bronchi or an air vesicle, to which place they may be conducted by any catarrhal condition that may be present, and especially easily when the la grippe germ is at work.

Among the inmates of damp, ill ventilated, dark, and crowded dwellings, pneumonia occurs the most frequently, although prolonged exposure to cold, and especially such exposure after exhaustion, is a strong predisposing cause. Also, the presence of some other infection, such as measles, whooping cough, influenza, or typhoid fever is a frequent cause of this disease. As for tubercle bacilli so are these dark tenement houses breeding places for the pneumococci, and certain houses can positively be stigmatized as pneumonia breeders. From these places the pneumococcus is disseminated, and no walk of life is exempt from its onslaught. The disease is also certainly communicable directly, hence pneumonia should be a reportable disease, and the boards of health should begin to disinfect tenement rooms after pneumonia as they now do after a case of tuberculosis.

The first consideration in the treatment of pneumonia should be the same care as to hygienic surroundings as we take with a typhoid case, namely, a well ventilated, large room, with plenty of fresh air; then the oxygen tank will not be so often needed. Also a patient should be frequently moved from side to side to prevent hypostatic congestion of the unaffected lung.

I think that pneumonia can both abort itself and also be assisted to abort. This may not be frequently, but often is true. In rare cases in plethoric, sturdy men with a full, bounding pulse and marked signs of serious congestion of the lung, venesection can be done with good results. These, however, are the very cases in which fair sized doses of a cardiac depressant or a drug like antipyrin will also be of advantage. The profuse sweating caused by a gramme of antipyrine, with the action of some brisk purge, followed by morphine to stop the pain, and dry cupping, or if preferred, a hot poultice, may and often does abort a case of pneumonia. The old treatment with aconite and veratrum viride will probably give the same results. Personally I do not use these drugs, as I fear prolonged cardiac depression, much greater than can possibly come from one dose of an antipyretic. There certainly is no justification for

giving cardiac depressants or coal tar products after the first stage of pneumonia.

The case not aborting and the pneumonic process proceeding, the general management becomes of importance. The nutrition should be sufficient, but not so forced as to cause gastric flatulence or tympanites, any fermentation in the bowels not only adding its disturbance to the heart from the bowel distention, but also adding one more depressant and cerebral irritant by the absorption of bowel toxins.

The nutrition should be by milk, provided that it causes no indigestion, but probably it should not be given in such large amounts as we have been accustomed to give; a quart in twenty-four hours, combined with other nutriment, being better than two quarts. Two raw eggs a day, given in bouillon or coffee, or with sherry or brandy as seems best, furnishes the kind of albumen the patient needs. Expressed beef juice, which means more than the blood from meat, the actual, expressed meat serum, is one of our best heart muscle stimulants, and should be given in ounce doses three or four times a day.

The bowels should be moved daily, often best with small glycerin enemas, or, if the tongue is badly coated and there is some intestinal gas, a small amount of saline, such as hunyadi water, is indicated.

Troublesome, high temperature should be treated by sponging down with tepid water, sponging the extremities and the abdomen, but not the chest. Gentle massage of the extremities is advisable, with or without alcohol, as tending to promote the excretion of the muscle toxins and to establish a brisker peripheral circulation.

If the blood count shows the leucocytosis to be insufficient, or the patient seems not to be fighting the disease well, some nuclein preparation doubtless affords good treatment. This may be nucleic acid, in the dose of one grain three or four times a day, or thymus, in doses of three grains, or some other nuclein preparation. The dose of any of them, however, should not be large.

There is considerable difference of opinion as to the value or the advisability of local applications. Certain it is that warm, moist applications over the portion of the lung involved, during the first stage, will mitigate the pain and add to the general comfort of the patient. These applications may be of hot water, or water and alcohol fomentations, but nothing holds the heat better than the old flaxseed poultice bound tightly to the chest, especially if a hot water bag is placed alongside of it. Such applications should be

changed every two or three hours and not allowed to become cold. They certainly seem to promote easy expectoration and often apparently hasten resolution. In the case of children I am in doubt of their value. It has sometimes seemed to me that the continuation of poultices, at least for too long a time, has been the cause of stimulating, by dilating the blood vessels of the pleura, the pneumococcus to come out and make trouble, causing an empyema, which so frequently occurs in the pneumonia of children.

In stopping the use of the poultices I believe the best method is to gradually reduce their size, and then to put on some warm, dry absorbent cotton, when no chill will be felt and the patient will not miss the poultice. If the surroundings of the patient are such, that at certain times of the day or night the room becomes suddenly colder, or the patient cannot have the care of a good nurse, poultices had better not be used.

The question then arises as to the value of one of the glycerin pastes. They certainly make impervious dressings, but to get their best value, they should be changed at least daily, and better every twelve hours. I believe they do considerable good.

Among the poorer classes, where such changes or dressings are not advisable, the old pneumonia jacket may be used and do good. I do not believe in blistering or even in using iodine over the chest in pneumonia.

Many troublesome symptoms occur in pneumonia which need modification, and as already stated, although there is no specific treatment for this disease, certain it is that we can ameliorate the intensity of all symptoms. If there is an irritable cough, and not every cough produces expectoration, some sedative expectorant is indicated. Codeine seems to me better than morphine or heroine. Of course, the dose of any one of the opium series should be small, as the respiratory centre must not be depressed, and the patient must be alert to cough as frequently as there is anything to expectorate. There seems to me to be no better stimulant for the bronchial mucous membrane than ammonium chloride in small doses, especially if combined with a very small amount of ipecac; this, put up in an acid preparation, is almost invariably well received by the stomach. The time of sweet, nauseating cough mixtures has gone by. A little syrup of citric acid or dilute phosphoric acid in watery solution and given well diluted, makes a good menstruum, and is almost invariably well received by the stomach. I believe there is very little advantage in giving ammonium carbonate, as other car-

diac stimulants are more pleasant, and it is very irritant to the stomach. If the pneumonic expectoration becomes very profuse terpene hydrate, in capsules or tablets, becomes a good treatment.

Now as to the care of the heart, and especially the use of alcohol. I do not believe alcohol should be given simply because we have a case of pneumonia, but should be given only when the circulation seems to demand it. This means that it is not to be relied upon for a long time in cardiac depression, although for a short time it will tide over such depression and whip up a flagging heart. By its tendency to dilate the peripheral blood vessels and bring more blood to the surface and cause perspiration, especially when the skin is dry, and also where not enough nutriment is taken, it certainly has value. The enormous doses of whiskey given, and recovered from, are certainly not advisable. The dose should be such as not to give strong odor to the breath, not to cause a dry skin or a bounding pulse, but just enough to keep the surface of the body warm and the pulse regular. This means from one to three teaspoonfuls of whiskey every three hours, provided that the heart has shown signs of weakness. If the heart still fails, and the pulse tone is poor and the rate rapid, not more whiskey should be given, but other cardiac stimulants. Many cases of delirium are caused by an overdose of alcohol in acute disease. In cases of high fever, alcohol is doubtless a fat saving food, as it aids in furnishing something for the system to burn, although it may not save proteid material. In cases of very low temperature, alcohol is not the best stimulant.

Many times, instead of alcohol, nitroglycerin can be used to equalize the circulation, dilate the arteries, and render a tense pulse less hard. The dose for this purpose is $\frac{1}{200}$ of a grain every three to six hours. Also, in an emergency a hypodermic of $\frac{1}{100}$ of a grain of nitroglycerin will give a flagging heart a start and allow time to get the action of other drugs.

As it is generally the right side of the heart that fails, if there is much cyanosis and the veins are dilated, with jugular throbbing and a laboring heart, venesection of a few ounces of blood will relieve this condition as well as the hypodermic of nitroglycerin, as just stated.

In any stage of pneumonia, if the pulse shows very poor tension and becomes irregular, whether the rate be fast or slow, strychnine is indicated, and should be given in soluble tablets at the rate of $\frac{1}{30}$ of a grain every six hours. If the heart becomes still weaker, and cardiac failure is feared,

it should not at first be given more frequently, but rather every twelve hours or every six hours, hypodermatically, at the same dosage.

Caffeine should be given from the beginning of pneumonia in the form of coffee, at least once in the morning, and perhaps several times early in the day, but not late in the day on account of preventing sleep. Coffee, besides being something of a food, is certainly a decided cardiac stimulant and tonic.

If a patient is very sleepless and it is decided that the caffeine should not be used, aromatic spirit of ammonium, or camphor water, or spirits, makes a good substitute. In acute heart failure, the hypodermic injection of the saturated solution of camphor in olive oil may be used, and repeated every half hour, several times if needed. I have never seen an abscess from such an injection.

Also, when the pulse tension begins to worry us, but not too soon, adrenalin or suprarenalin solution, one part to a thousand, should be used in drops on the tongue, five drops every fifteen minutes, several times in an emergency, or five drops every three hours regularly. I wish to caution against using suprarenal extract in large doses or for too long a time, as I believe depression occurs from it, so that as soon as the emergency is passed it is better to reduce the frequency or omit the drug entirely for a while.

Now as to oxygen. In severe cases of pneumonia it certainly does no harm to have a tank of oxygen on hand, as in emergencies it is of undoubted value. If a patient can afford to use it freely, it will relieve the dyspnea of the worse stages and certainly it is an aid in cardiac depression. However, it is not curative and should not be expected to work miracles.

If for any reason, sufficient liquid is not taken by the patient, or the kidneys are not acting well, a high injection of normal saline solution is of great value, provided there is no oedema anywhere. If there is pulmonary oedema, and the heart is failing, saline transfusions or injections should not be used, as the circulation has already all that it can take care of, and it is a mistake to give saline solutions in failing heart unless there has been hæmorrhage or large loss of fluid.

During convalescence from pneumonia, if the pulse and heart are weak, there is no better cardiac tonic than tincture of strophanthus in five to eight drop doses every six hours.

One of the most troublesome symptoms in pneumonia is sleeplessness, and if this cerebral irritation goes a step farther there is delirium; there is nothing in medicine much harder to combat than a noisy delirium from pneumonia, and

the prognosis is very grave. Perhaps chloral is the best hypnotic, especially if delirium is present, but we must consider the possibility of its causing cardiac weakness and perhaps we should combine it with a good cardiac tonic. Hyoscine may be used hypodermatically, and is often very successful; paraldehyde may be of value, but I believe the bromides should not be given, as they tend to cause too much cardiac debility.

Ergot is a good drug for all cerebral congestions and irritations, and may be used hypodermatically. It contracts the blood vessels of the brain and raises the blood pressure everywhere, therefore it can do nothing but good to a weakened circulation.

Morphine should generally not be resorted to in delirium, as it requires very large doses to make any impression on excited brains, and large doses are dangerous.

Severe headache may be often well combated by an ice cap or a saline purge. Profuse perspiration, especially during the convalescent period, should not be discouraged, but the excretion should be carefully washed off with warm water, several times a day if necessary.

Nothing need be said of the serum treatment of pneumonia, as its use is as yet experimental and its value unproved.

HÆMORRHOIDS.*

By SAMUEL G. GANT, M. D., LL. D.,

NEW YORK.

PROFESSOR OF DISEASES OF THE RECTUM IN THE NEW YORK POSTGRADUATE MEDICAL SCHOOL AND HOSPITAL.

Hæmorrhoids are classified as *external* or *internal*, according to their location; the former being covered by the integument and the latter by the mucosa. According to their structure the external are further divided into the *thrombotic* and the *cutaneous* varieties, while of the internal there are also two types, the capillary and the venous. Occasionally one encounters pile tumors possessing characteristics of both the external and internal, their lower portion being covered by the skin and their upper part by mucosa; these have been designated *externointernal* or *combination* hæmorrhoids, and since they require practically the same treatment as the internal venous variety, they will not be discussed further.

Thrombotic hæmorrhoids usually occur in robust persons. Their onset is sudden and is caused by the rupture of one or more small veins during the expulsion of hardened feces. They are usually single, although occasionally there may be two or more; are located at the mucocutaneous junc-

* Read before the Harlem Medical Society.

tion, and vary in size from that of a millet seed to that of a cherry. They are ovoid in shape, livid or dark blue in color, and appear and feel like bullets or small shot beneath the skin. At first they cause a sensation of swelling at the anal margin; as the clot becomes larger and harder there is a feeling as of the presence of a foreign body in the lower part of the anal canal. This is resented by the sphincter, which spasmodically contracts, occasionally at first producing a drawing sensation; later the contractions become more frequent and of longer duration, and intense suffering is experienced because of the almost constant constriction of the pile.

The suffering caused by a thrombotic hæmorrhoid becomes so intense that the patient is unable to sleep or obtain relief, no matter what position he assumes. Because of the tenesmus, irritation by the fæces, and sphincteralgia, they soon become highly inflamed and very sensitive. Even if not treated the clot may be absorbed; occasionally, however, the tumors become ulcerated as the result of continued irritation, infection of the clot takes place and marginal abscess terminating in fistula results.

Cutaneous hæmorrhoids consist of hypertrophied elongations of the skin, and are frequently secondary to the absorption of the clot in thrombotic hæmorrhoids, where the skin is bruised or stretched. They may be single or multiple, are usually chronic, irregular in shape, of variable size, and except when accurately inflamed, are the color of the skin. Cutaneous hæmorrhoids cause less suffering than the thrombotic variety; in fact, they may exist for years without causing the patient any trouble, providing proper care is observed. But when bruised from any cause, such as a kick or fall, sitting on a hard seat, stretching of the parts during defæcation, etc., or when irritated by acrid discharges from the rectum or vagina, they may become inflamed and produce much pain and annoyance. When the inflammatory process is subacute, the pain is slight and the patient complains of heat and fullness about the anus and discomfort during defæcation.

When acutely inflamed, cutaneous piles become greatly swollen, highly colored, cedematous, painful, extremely sensitive to the touch, and cause frequent spasmodic contractions of the sphincter muscle. The pain is usually confined to the anal region, but may be reflected up the back, down the limbs, or to neighboring organs.

Capillary hæmorrhoids consist in a dilatation of the capillaries of the mucosa, the vessels beneath the membrane being rarely involved; they are flat, project slightly above the surrounding mucosa,

are bright red in color, soft and spongy, and have a strawberry like appearance. They are uncommon, may be single or multiple, and vary from one fourth of an inch to one inch in diameter. They bleed very frequently, but the hæmorrhage is of an oozing character, and usually not profuse. They cause but little pain, rarely protrude, and may occur alone or in conjunction with the internal venous variety.

Internal venous hæmorrhoids are varicosities involving the veins and capillaries of the mucosa and submucosa in the lower rectum, and are characterized by a tendency to bleed and protrude. They may cause very slight or very intense suffering depending upon their number, size, and location, and whether they are in an inflamed condition, ulcerated, or strangulated. In their incipency they are small, rarely protrude, and cause but little discomfort other than sensations of heat and fullness about the anus; but later on, when they become larger and protrude more frequently and become ulcerated, they may produce considerable pain during and following stool. When strangulation occurs and the tumors cannot be returned above the sphincter muscle because of its spasmodic contraction, the suffering thereby induced is most agonizing, and it is impossible to obtain rest or relief until the strangulation is overcome.

Hæmorrhage from these hæmorrhoids is venous in character, and may be slight in amount, appearing only as streaks upon the fæces, or moderate oozing from the anus for some time after stool, or so profuse that the patient is partially or completely exsanguinated; the blood may be discharged fresh and fluid, or if retained for a considerable time in the bowel, in clots resembling coffee grounds.

Other symptoms which may be induced by internal venous hæmorrhoids are vesical and prostatic disturbances, proctitis and reflected pain. When ulceration is extensive the discharges may cause excoriations of the anogluteal region, producing a persistent annoying pruritus. If infection occurs abscess and fistula may follow.

Treatment.—The treatment of hæmorrhoids when intelligently carried out is universally successful. It may be non-operative or operative, but when left to the surgeon to decide, the latter method is by far the more satisfactory, as it gives the quickest relief and effects a permanent cure.

The non-operative treatment is simple and consists in requiring the patient to remain in the recumbent position, in restricting the diet to liquid and semisolid foods, regulating the movements of the bowels by the administration of laxatives in

order to secure one or two semisolid stools daily, applying the ice bag, and in exhibiting astringent remedies to diminish the inflammation and swelling, so that the hæmorrhoids may be reduced. If they are strangulated and there is much pain and sphincteric spasm, it is best to apply hot water compresses, or poultices, and insert suppositories containing a quarter of a grain of morphine, eucaïne, or cocaine as often as is necessary to give relief. In cases marked by depleting hæmorrhages, with or without protrusion, the bleeding may be arrested and the ulceration diminished by the daily insertion of a small plug of gauze about the size of the little finger and three inches in length, moistened with a solution of silver nitrate two per cent., ichthylol ten per cent., or balsam of Peru, fifty per cent., which is allowed to remain several hours in the anal canal. When this is not efficient, the ulcers should be cauterized with the Paquelin or galvanocautery. In most instances, however, this method of treatment is only palliative, and an operation eventually becomes imperative.

The operative treatment of hæmorrhoids has been practised certainly since the time of Hippocrates, and numerous operations have been suggested for their cure, some of which have proved useful, simple, and effective, while others are but little short of barbaric, are unreliable, cause great suffering, and not infrequently leave the patient in a condition far worse than before the operation.

The operations which are most frequently practised for the relief of internal hæmorrhoids are (1) clamp and cautery; (2) ligature; (3) excision; and (4) the injection method. Other operations have been suggested, such as submucous ligation, divulsion of the sphincter, crushing, removal by *écraseur* or galvanocautery, wire loop, cauterization, puncture or linear, or by means of caustics; but these will not be discussed further in this paper as they have become obsolete, or have met with but slight favor at the hands of the profession.

The procedures which have proved most popular and reliable are the clamp and cautery and the ligature operations. The writer is partial to the former, especially when *general anæsthesia* is employed; but either method when properly performed is invariably followed by satisfactory results. The excision operation for hæmorrhoids, originated by Whitehead, of England, and modified by Pratt, of Chicago, wherein the lower two or three inches of the rectal mucosa are completely excised, cannot be too severely condemned, because of the difficulty of performing the opera-

tion, and the grave complications and sequelæ which so often occur, such as obstinate ulceration, stricture, incontinence, abscess, pruritus, etc., not infrequently leaving the patient in a permanent state of invalidism. Hæmorrhoids may be excised, however, by means of elliptical or other incisions sufficient to remove the tumors, but leaving strips of healthy mucosa undisturbed, thereby avoiding retraction of the bowel and its troublesome sequelæ.

A great deal has been written concerning, and much has been claimed for the injection method or operation by its advocates, who maintain that by the injection of caustic or astringent fluids into hæmorrhoids, they can be cured, causing but slight if any pain and without detaining the patient from his business or requiring him to take a general anæsthetic. Experience has convinced the writer that, although cures are occasionally obtained by this method, yet in most instances it is unsatisfactory, in that permanent results are not attained, and further because the injection of carbolic acid and similar agents may produce much pain, swelling, extensive sloughing, abscess, fistula, phlebitis, and long delay from business; even cases of death from embolism have been reported. Therefore, this method once so popular with the laity has fallen gradually into disrepute.

At the present time it is the custom of most surgeons to insist that patients suffering from hæmorrhoids, irrespective of their number, size, or condition, must forego business and social engagements to enter the hospital for operation under general anæsthesia. The writer is convinced that this is unnecessary and indeed unjustifiable in the vast majority of cases, and during the last three years he has succeeded in permanently relieving nearly all of his hæmorrhoidal cases by radical operation, performed under local anæsthesia in the office, patient's home, or dispensary.¹

With but very few exceptions, uncomplicated cases of hæmorrhoids, irrespective of variety or condition, can be radically operated upon, outside the hospital under local anæsthesia produced by the injection of eucaïne or cocaine or of sterile water. While the anæsthesia produced with cocaine and eucaïne is satisfactory, dangerous toxic effects not infrequently accompany their use; there is often copious bleeding during and shortly following the operation, and after the immediate anæsthetic effect has worn off, the postoperative pain is severe and prolonged. Because of their disadvantages, the

¹ A Plea for the Non-Hospital or Office Treatment of Diseases of the Rectum and Anus, by Samuel G. Gant, M. D., LL. D., *New York Medical Journal*, April 18, 1903.

writer has discarded these agents in the treatment of hæmorrhoids, and now operates under local anæsthesia induced by distending the tissues by means of injections of sterile water,² the pressure exerted upon the terminal nerve filaments being sufficient to prevent cutting pain, although some patients suffer momentary discomfort caused by the distention, this being immediately relieved when the tissues are excised. This method is devoid of danger of poisoning, there is almost no bleeding during the operation and little if any pain following it, while the dangerous postoperative hæmorrhage has been extremely rare.

The methods employed by the writer to produce local anæsthesia for operations in the ano-rectal region by the injection of sterile water into the tissues, have already been fully described and published recently in the *New York Medical Journal* and *Philadelphia Medical Journal*,³ and it is therefore unnecessary to enter into detail here, further than to reiterate that sufficient water must be injected to distend the tissues until they are of a glassy white appearance, when anæsthesia is complete.

In the thrombotic variety of external hæmorrhoids the water is deposited only between the layers of the skin, and the tumor is then transfixed, laid open, the clot turned out, and its cavity packed with gauze. In the cutaneous variety the injections are made into both the skin and the centre of the tumor; the latter is then excised and the wound sutured or left to heal by granulation.

Internal hæmorrhoids are first anæsthetized by injecting sufficient water directly into the centres of the tumors; they can then be painlessly operated upon by the ligature, clamp and cautery, or linear excision methods. The clamp and cautery is satisfactory when the operation is performed at the home of the patient and he remains in bed for a short time afterward, but when it is performed in the office or dispensary, and he desires to be up and about immediately after it, the ligature method is safer because less apt to be followed by hæmorrhage.

In the vast majority of cases, the patients complain of little or no pain on the days following the operations, other than slight soreness. This the writer attributes to careful divulsion of the sphincter muscle by insertion of the fingers or anal calibrator, prior to the operation, to the use of a very fine and soft but strong linen ligature; to the fact that no dressings are left in the anal

canal to irritate the wound or excite sphincteric spasm, and that the stools are kept in a semisolid state by the administration of laxatives.

The patient is made more comfortable and the danger of bleeding lessened if a wedge-shaped compress of gauze is applied to the anus after the operation and held firmly by means of a snug fitting T bandage. In order to prevent the secretions from collecting and irritating the skin, which may cause itching, and to relieve pain and sphincter algia should it occur, gauze compresses wrung out of water as hot as can be borne by the patient should be applied frequently as may be convenient. Should this not suffice to relieve suffering, ointments, or suppositories containing opium, cocaine, or eucaine alone or in combination may be prescribed to be used as often as required.

In case of profuse accidental or secondary hæmorrhage, the bleeding can be quickly arrested by introducing a good sized proctoscope, through which a thick plug of gauze is inserted into the bowel and held in place, while the proctoscope is withdrawn over it, the lower end of the gauze being allowed to project from the anus; the wedge-shaped compress and T bandage are then replaced.

The writer, in conclusion, would state that he has operated upon more than two hundred and fifty cases of hæmorrhoids, under sterile water anæsthesia with the most gratifying results; one hundred and eighty-six of these were included in a collection of three hundred and twenty cases of various rectal operations, performed under this method of anæsthesia and reported at the recent meeting of the American Proctological Society. This group of operations embraced every variety of pile tumor, under all conditions ordinarily encountered, and effective radical treatment was rendered by this method, so simple and easy to accomplish in the office, patient's home, or dispensary, without resorting to general anæsthesia and with so little danger and inconvenience to the patient, that in the writer's opinion it should relegate to oblivion the much vaunted but uncertain and dangerous injection method of treating hæmorrhoids which has accomplished little and caused much suffering, but nevertheless has enabled the quacks or medical vampires throughout the country to extort enormous sums from this class of sufferers.

PNEUMOCOCCUS ARTHRITIS — REPORT OF A CASE.

By W. H. WITT, M. D.,

WITH PATHOLOGICAL REPORT.

By WILLIAM LITTERER, M. D.,

NASHVILLE, TENN.

Cases of arthritis demonstrated to be of pneumococcus origin are still sufficiently interesting to deserve a report. In 1899 I had a case of arthritis of the right knee complicating pneumonia in a man aged 66 years. The fluid from the joint was not tested bacteriologically. There was also extensive infection of the calf of the leg. The process made such progress that a successful amputation at the middle of the thigh was eventually done. At that time only one textbook at my command even mentioned such a complication of pneumonia and I could find no help in the current literature. The article by Cave which appeared in the *Lancet* of January 12, 1901, was the first that came under my observation. It was, I think, the first that appeared in English. Since then several cases have been reported by Cole, Howard, and others. I have recently observed the following case:

G. N. B., aged 36 years, very good personal and family history, was seized with chill January 22, 1904, and was attended by Dr. Haley, of this city. Signs of pneumonia gradually developed in both lungs, and in a few days he was very ill. I saw him January 28th. The urine became scanty and loaded with casts, and a fatal issue was expected. Under hypodermoclysis and hypodermic injections of caffeine his condition improved, and he seemed in a few days to be on the road to recovery. On February 7th, I saw him again and there was evidence of fluid in his left side. Some of the fluid was removed and tested bacteriologically. The next day a resection of a rib was done, and a pint of purulent fluid taken from his pleural cavity. On this day the right knee began to swell rapidly, and fluid was aspirated from its cavity. The patient was very septic, and gradually sank and died on February 10th. A few hours before death the right arm swelled from the elbow to the hand. This was probably due to a septic thrombosis, said to be one of the very rarest complications of pneumonia. There was no autopsy. I append the report of Dr. Litterer.

BACTERIOLOGICAL REPORT FROM THE LABORATORY OF THE MEDICAL DEPARTMENT OF VANDERBILT UNIVERSITY.

The fluid aspirated by Dr. Witt from the right knee joint was yellowish, serum like, and slightly turbid. Cultures from this were made in milk, on

plain and glucose agar plates, and on blood serum slants.

The next morning all the plates and slants showed many small, opaque, white, circular pin point colonies. Smears were made and showed diplococci which in shape and staining reactions were identical with the *Diplococcus pneumoniae*. From the milk, smears stained by Welch's method demonstrated typical lanceolate diplococci with a fairly definite capsule. The above organisms were run through the various media and showed typical growth in glucose, glycerin, and plain agar slants, bouillon, blood serum, litmus, milk, and gelatin, and the provisional identification as the *Diplococcus pneumoniae* was fully confirmed.

A few drops of a thirty-six hour glucose bouillon culture injected subcutaneously in a mouse caused death in forty-eight hours; $\frac{2}{10}$ cc. was inoculated intraperitoneally into a rabbit and caused death in thirty-six hours. The organism in both the mouse and rabbit was recovered in pure culture from the heart blood and peritoneum. Smears stained by Welch's method showed beautiful typical lance or barley shaped diplococci with distinct capsules. The cultural and tinctorial characteristics were identical with those of the original stock. After passing the organism through several mice the virulence was increased until it killed in eighteen hours.

Cultures were made from the pleuritic effusion and showed many colonies of *Staphylococcus pyogenes aureus* and the *Diplococcus pneumoniae*, the former predominating.

Officers of the American Association for the Advancement of Science.—The following officers were elected for the coming year:

President, Calvin M. Woodward, of Washington University; vice-presidents, mathematics, Dr. W. S. Eichelberger, United States Naval Observatory, Washington; physics, Professor Henry Crew, Northwestern University; chemistry, C. F. Mabery, Case School of Applied Science, Cleveland; mechanical science and engineering, F. W. McNair, president Michigan School of Mines; geology and geography, Professor W. North Rice, Wesleyan University; zoology, Dr. Henry B. Ward, dean of medical faculty, University of Nebraska; botany, Professor Irwin F. Smith, United States Department of Agriculture; anthropology, Dr. George G. MacCurdy, Yale; social and economic science, Dr. Irving Fisher, Yale; physiology and experimental medicine, Dr. William T. Sedgwick, Massachusetts Institute of Technology; permanent secretary, Dr. Leland O. Howard, Department of Agriculture, Washington; general secretary, Professor Clarence A. Waldo, Perdue University; secretary of the council, John F. Hayford, United States Coast and Geodetic Survey; secretaries of the sections, mathematics and astronomy, Professor L. G. Weld, Iowa University; physics, Professor Dayton C. Miller, Case School of Applied Science, Cleveland; chemistry, Professor Charles L. Parsons, New Hampshire College; mechanical science and engineering, William T. Magruder, Ohio State University; geology and geography, Dr. Edmund O. Hovey, American Museum of Natural History; zoology, Professor C. Judson Herrick, Denison University, Ohio; botany, Professor F. E. Lloyd, Columbia University; anthropology, George H. Pepper, American Museum of Natural History; social and economic science, John Franklin Crowell, Bureau of Statistics, Department of Commerce and Labor; physiology and experimental medicine, Dr. W. J. Gies, New York College of Physicians and Surgeons; treasurer, Professor R. S. Woodward, president Carnegie Institute, Washington. It was decided to hold next year's convention in New Orleans, beginning on December 29th. Boston was recommended as the place of meeting for 1906. No summer sessions will be held next year as has been the custom in the past.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXV.—What is your experience in the therapeutical use of yeast? (Answers due not later than January 16, 1905.)

XXXVI.—How do you treat bunions? (Answers due not later than February 16, 1905.)

XXXVII.—What diet do you prescribe in typhoid fever? (Answers due not later than March 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but NOT REQUIRED) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the NEW YORK MEDICAL JOURNAL AND PHILADELPHIA MEDICAL JOURNAL (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The price of \$25 for the best essay submitted in answer to question XXXIV has been awarded to Dr. Lucien Lofton, of Emporia, Va., whose article appears below.

PRIZE QUESTION NO. XXXIV.

THE NON-OPERATIVE TREATMENT OF INTERNAL HÆMORRHOIDS.*

By LUCIEN LOFTON, A. B., PH. D., M. D.,
EMPORIA, VA.

I have successfully cured within the past four years sixteen cases of internal hæmorrhoids by the following original method: Preliminaries are of course gone through before treatment is begun, as is usual in surgical procedures. Arming an all metal hypodermic syringe with two drachms of boiling water or, preferably, decinormal salt solution equally hot, you exclude all air from the needle. Have the patient assume the knee-chest or Sims's position. By carefully inserting one of the latest improved rectal specula you bring into view the field of operation. You proceed to attack one and all of the sacs exposed by thrusting the needle approximately half through the tumor, where from ten to fifteen drops of the solution are deposited. After waiting a second or two, pull the syringe needle out about one sixteenth of an inch and repeat the injection, the last deposit of the fluid being made directly beneath the mucous surface. You may attack each sac at

various points at one sitting if you desire, and go boldly to the base of each pile in addition. There is practically no pain to the operation, if you desire to call it such. Be careful to keep the salt solution or water as hot as possible, as this means success, and there will be failure if it is lukewarm. A gradual slough of the diseased tissue takes place in from six to twenty days, and healing usually occurs rapidly, provided the stools are kept mushy. Not one, but ten piles can be treated at one time by this method, and usually one thorough application will suffice. No rest or detention from business is necessary. The cure is simple, safe, and sure; no embolism will result.

Dr. Everett S. Hicks, of Port Dover, Ontario, writes as follows:

We will take it as granted that we have eliminated or have used appropriate treatment for such complications or causes as urethral stricture, retroflexed uterus, stone in the bladder, etc. In all cases attention should be drawn to certain points:

1. Diet.—As a rule, we advise abstinence from alcohol, coffee, tea, cheese, cabbage, beans, and very coarse breads. Our diet will be aimed at the relief of constipation and the production of a soft stool.

2. To avoid acute inflammatory attacks, we caution the patient to treat diarrhœas early, to avoid sitting on cold or wet surfaces or on upholstered chairs, generally to avoid bicycling and horse-back riding or excessive sexual intercourse.

3. We note the occupation and prescribe exercise, generally walking, to suit the case.

4. We advise rigid cleanliness and in many cases the use of cold water after the stool.

5. We treat constipation as we would treat it in any case, drawing special attention, however, to the usefulness of injections to soften the fæces, to water drinking as a habit, and to the avoidance of straining. Show the patient how much straining can be avoided in cases of hardened fæces by pushing forward on the fæcal mass with the fingers placed between the coccyx and the anus. We advocate as a laxative sulphur, occasional doses of calomel or compound licorice powder, or podophyllin with hyoscyamus or strychnine in full doses may be added.

6. In cases with portal congestion we use static purgings and abdominal massage as auxiliary measures.

7. We have found it wise in many cases to advise the patient to have the daily stool at bedtime, so that any inflammation caused may be improved by morning.

Coming to the piles themselves, our most urgent cases will be those with a history of profuse

* Our contributors are correct in supposing that the expression, "without an operation," does not bar out injections.

recurrent bleedings. In the worst cases this is usually due to hæmorrhage from a small artery.

Ointments are a waste of time. Put the patient in the Sims or lateral position and ask him to strain. As he strains, evert the mucous membrane of the rectum with your fingers, holding all you gain between the straining efforts. Using your free hand to wipe away the blood, you will soon see it coming in jets from one small spot. Touch this spot thoroughly with fuming nitric acid or strong liquor ferri perchloridi. Other cases with bleeding will usually be venous. Ointments may be applied by the finger or with the pile pipe. Suppositories are fully as useful. As astringent remedies, tannic acid or the subsulphate of iron will do well. I have found witch hazel, distilled or colored, a useful injection or pledget application, and I have had success with adrenalin in some cases in which an examination was declined. For the pain, cocaine, 10 to 20 grains, and chlorotone, 60 to 100 grains to the ounce of vaseline, are very satisfactory. Other anodynes include morphine, hyoscyamus, belladonna, and iodoform. Our patients will regard as non-operative such radical measures as the injection treatment. After one lesson I have never used this measure in inflamed cases, or on more than two piles at one sitting, the sittings being seven to ten days apart. Ask your patient to strain down the piles and grasp the one to be treated with a volsella, injecting into it sufficient of the weakest Schleich solution to blanch it. Wait a minute and inject from five to fifteen drops of a solution of carbolic acid, 1 part; glycerin, 3 parts; and water, 3 parts. Morphine may be needed afterward, and your patient may be forced to bed even with this treatment, which is milder than that usually recommended. Galvanic electrolysis is useful to dispel hard nodules left after the injection treatment, or as a cure for chronic pile tumors that are not too vascular. We still have left the cases with inflammation, prolapse, and strangulation. As a prophylactic measure we may use a mechanical support or advise the wearing of glass dilators at night, thus keeping the parts in position and affording some compression. If the piles are strangulated, put the patient in the knee chest position, grease the tumors, and put them back by taxis, working in one point at a time. If unsuccessful, give ether to primary anæsthesia, dilate the sphincter, and try again. Such cases can be left to nature. Raise the buttocks, apply ice or hot poultices, and use morphine as required.

Palliative treatment will be fairly successful if we refuse to treat a case without examination and combine our remedies to suit the case as examination shows it to be not as the patient says it is.

Dr. Elizabeth Mercelis, of Montclair, N. J., writes as follows:

In a consideration of the non-surgical treatment of internal hæmorrhoids there must be outlined the treatment for cases with acute and those with subacute symptoms, as well as the general measures beneficial to both.

The cases with symptoms of considerable severity are best treated by putting the patient to bed at once. Elevation of the hips by pillows and the assumption of the knee chest position at intervals are desirable. Next in importance is the application of cold or heat, according to the preference of the attendant. Cold may be effectively applied by giving small repeated enemata of chilled water, or sometimes even the introduction of a small piece of ice is of service. Hot or cold rectal irrigation (the rectal return flow irrigator being used) is of great service. Where hot water is used it is desirable to continue the irrigation for ten or more minutes, repeating it as indicated.

With cold, applications of shorter duration act best, as the astringent action is immediate, and if the cold is too long continued, relaxation may supervene.

Enemata, hot or cold, may contain drugs, usually astringents, such as nitrate of silver, tannin, etc., and are with advantage followed by a very small oil enema, which is retained. Unless an enema is given for the purpose of emptying the colon, a small one, of not more than eight ounces (sufficient to reach the diseased portion of the rectum, and being usually retained), is much more satisfactory.

Where the pain is severe it may be necessary to use an anodyne in some form. Starch water enemata containing deodorized tincture of opium or a suppository of opium and belladonna, or of iodoform alone or with belladonna, are useful. Where an idiosyncrasy exists for these, cocaine may be used with immediate relief, but is not so effective, as there may be relaxation of the capillaries as the effect wears off.

Electricity—the alternating or sinusoidal current, one pole within the rectum—may help greatly in relieving the pain and improving the pathological condition. The same may be said of the fine massagelike movements of the best vibrators. With this instrument, also, the soft rectal point is gently introduced through the sphincter, the action thus being strictly local.

Lastly, where there is abrasion of the membrane, topical applications may be indicated, as of silver nitrate, nitric or chromic acid, ichthyol, iodoform, witch hazel, etc. A rubber bag covered with an ointment containing any one of these or some other drug may be introduced into the rec-

tum, then inflated and left in position. This brings uniform pressure upon the distended blood vessels. In some cases this procedure produces an increase of pain, and must be abandoned.

In subacute cases the treatment must be directed toward establishing the ultimate integrity of the rectal wall. Of local measures, the most important is daily cold rectal douching or enema followed by astringent suppositories (i. e., containing ergot, krameria, etc.). Cold forcible douching of the sphincter ani and perinæum (the fountain bag hung high and a small tip used) is of benefit, as is also the cold spray over the sacrum and hips.

Diet is perhaps the most important of the general measures, for upon it depends to so great a degree the regulation of the bowels. Where constipation or constipation alternating with diarrhœa exists, a diet containing an abundance of fat foods, leaving a large residue, and fruits is usually indicated. The resulting stool should be pultaceous and normally evacuated.

If there is persistent diarrhœa, the intestinal indigestion may best be controlled by a simple and limited diet. Other causes of constipation, such as fissured anus, tumors, etc., or of diarrhœa, such as extreme nervous conditions, fecal impaction, etc., must be studied and treated.

An average amount of active exercise is desirable, and rest on the back should preferably follow such exercise. Exercises of the leg and abdominal muscles, which do not increase pelvic congestion, are indicated, as are also general massage and stimulation of the sacral nerves by tapping over the sacrum.

The knee chest position two or three times daily is of advantage. To be avoided is long continued standing or work which brings much strain upon the abdomen, also marked fatigue from any cause.

Of cathartics, any, such as aloes, which increase the congestion of the lower bowel should be avoided. As an example of a good one for use in these cases may be mentioned the compound sulphur tablets, several being given three times a day, as needed. These produce a stool of good consistence, which is of so great importance.

General tonics are indicated. *Nux vomica*, strychnine, and bitters stand first perhaps, though many others may be used with advantage. Iron preparations act least satisfactorily.

Dr. G. N. Murphy, of Paducah, Ky., writes as follows:

I have treated internal hæmorrhoids for the past six years without an operation with

great satisfaction by the following method: Have the patient clear the bowels with salts on the day before the treatment. At the time of treatment I wash the lower bowel with hot water enemata, and when all the water is expelled, which is in about forty minutes after the enema is given, the patient is placed on his side on a table or bed in a good light, and requested to extrude the pile tumors by straining down. Large tumors are easily brought into plain view and held down for treatment, but small ones are with difficulty exposed sufficiently to be treated outside the sphincter, and have to be treated through a conical slide speculum. I use one of the Brinkerhoff variety.

The larger tumors are treated outside the sphincter muscle, as they are easily held down and need no mechanical aid to keep them exposed.

These tumors, large and small, I inject with a fifty per cent. carbolic acid solution, made according to W. P. Agnew's formula, using just enough of the fluid to turn the tumor white or of an ashen gray color.

The amount of fluid injected is a matter of judgment purely, and only experience can teach the proper amount to use in any given case, but the aim is to use enough to unite with every unit of tissue of the tumor. In a tumor no larger than a pea two minims are sufficient to produce necrosis, but in one as large as a small hen's egg, from four to eight hypodermic syringefuls are required. Large tumors require from twenty to thirty minutes of time to inject properly, and should be greased with vaseline and returned within the sphincters. The patient is advised to keep off his feet for four or five days and take only a liquid diet. The bowels should be moved with a warm water enema the first time a movement is desired after treatment. The bowels should be confined for three or four days after the tumors are injected. Disintegration generally takes place and the tumors come away by sloughing in from five to eight days.

The wound generally heals in about ten days to two weeks thereafter.

Sometimes there is considerable hæmorrhage following the sloughing of those large tumors, and in one case in my practice the rectum had to be packed with gauze for a few days to control the bleeding. I have never seen sepsis follow this treatment. Prior to the adoption of this method of treating internal hæmorrhoids I practised the knife and ligature operation exclusively in all forms of hæmorrhoids. My reasons for using and recommending the hypodermic injection method

Dinner to the Health Commissioner of Baltimore.—Dr. James Bosley, city health commissioner of Baltimore, was entertained on December 27th at the Hotel Rennett by the employees of the city health department. Since Dr. Bosley's connection with the city government he has refused to accept presents such as are usually made to the heads of the various departments, and it has become an annual custom of the employees of the department to tender him a banquet.

NEW YORK, SATURDAY, JANUARY 7, 1905.

RAILWAY SLAUGHTER IN THE UNITED STATES.

It has long been known that our American railways were open to the reproach of being operated without due regard to safety, as shown by the appalling lists of their killed and injured as compared with similar lists pertaining to railway work in other countries. But there has been no adequate realization on the part of the public of the disgrace of this state of things, and there has been no sufficient action taken by legislative bodies to do away with an utterly needless, because almost entirely preventable, loss of life. It is to be hoped that an article published in the January number of the *World's Work*, written by Mr. Leroy Scott, will do much toward arousing a public sentiment that will exact the necessary reform.

Undoubtedly the medical profession's greatest present title to general admiration is its determined and persistent devotion to preventive medicine. The duty of such devotion it could not have evaded and still have professed solicitude for the public welfare. None the more, it seems to us, can it longer avoid taking an active part in promoting reform in this matter of railway homicide. If it is our duty to do everything in our power to prevent death and impairment of health by disease, we are under no less an obligation to do our best to prevent such results

from violence. We fully realize that many lives are saved and that much disability is prevented by the admirable surgical service maintained by many of our more important railways. But this is not enough; it is much better to prevent a collision, for example, than to save the lives or alleviate the sufferings of its victims. If we as a body make ourselves heard in the legislative halls—and we can certainly do so—there can be little doubt of our being able almost single handed to abate the horrors that have gone on unchecked for years. The railway companies are not ignorant concerning the means they ought to take to put a virtual stop to the continuous holocaust; let them be compelled to resort to those means, and let our profession be the prime mover in instituting the compulsion.

LIGATION OF THE SUPERIOR LONGITUDINAL SINUS FOR EPILEPSY.

Surely this is the era in which surgery is reaching out for new fields in all directions, and he would be a rash man who should say that we were yet at the end of operative novelties in the treatment of epilepsy. One of them, which its author seems to look upon as promising, appears to have been discovered by accident, like many another advance. M. Delagénère (*Archives provinciales de chirurgie*, October; *Semaine médicale*, December 14th) trephined a man who was an epileptic. In the course of the operation the superior longitudinal sinus was wounded at a point about a third of an inch behind the fissure of Rolando. To stop the hæmorrhage, the wound of the sinus was plugged with aseptic gauze, and the flap of scalp was immediately returned to its place and sutured. Not only did the man recover well from the operation, but his epileptic attacks ceased entirely, and the cure has now remained complete for more than two years.

Reasoning that plugging the sinus was equivalent to ligating it and attributing the favorable result in this case largely to the altered state of the subcranial venous circulation consequent on its occlusion, M. Delagénère deliberately tied the sinus in a subsequent case, and the result is reported to have been somewhat encouraging. There was a little headache for two days, and a week later there was slight dulness of the intellectual faculties, but the epileptic attacks were entirely absent for three

months. At the end of that time there was an exceedingly light seizure in which the patient did not fall or lose consciousness. It does not appear how frequent the paroxysms had been before the operation or for how long a time the patient was under observation after it.

There seems to be no particular difficulty in the operation itself. The proper site, about a third of an inch behind the fissure of Rolando, having been exposed by reflecting a flap of scalp and bone, a small anteroposterior incision is made through the dura mater about two thirds of an inch to one side of the median line. A transverse incision of the dura mater, crossing the median line and meeting the first cut, is made cautiously with a pair of scissors. Two catgut ligatures, about a third of an inch apart, are then passed around the sinus and tied tight. There is no need of dividing the sinus between the ligatures.

THE VICISSITUDES OF LACTATION.

While not in the least swerving from the well grounded conviction that the mother's milk is by all odds the most satisfactory food for an infant, we all recognize that maternal lactation is not wholly free from occasional defects. We realize this in a general way, and the textbooks take due notice of it, but it is to be feared that it is not sufficiently emphasized by clinical teachers. It is gratifying, therefore, to find that such a commonplace topic was recently taken by so eminent a teacher as M. Budin in a clinical lecture (*Journal des praticiens*, September 3rd). There is nothing startling or novel in what M. Budin had to say, but it is well to reiterate the teachings of every day experience for the benefit of the young practitioner.

The bad habit of allowing a half-sleeping infant to cling to the breast is still too prevalent, it is to be feared, among ill informed mothers. M. Budin insists that a newly born child should be nursed regularly every two hours, and that each nursing should last not longer than three or four minutes. Sometimes, perhaps without any assignable cause, a child fed at the breast gets out of condition and makes only feeble attempts at nursing. The consequence is that the mother's milk begins to grow scanty, and there is danger

of its failing altogether. Under such circumstances the child should be fed artificially for a few days, an older child, one that is healthy and strong, taking its place at the breast. The probability is that the rightful nursling will speedily regain its avidity for the breast, and it may then be returned to its legitimate source of nourishment.

Occasionally the mother's milk is either deficient in fat or contains too much of that element. It is well to remember that the milk that first flows contains less fat than that which is drawn subsequently, and to manage the nursings accordingly. The occurrence of menstruation in the mother is apt to derange the child's digestion, but the derangement is only very temporary, and the return of the menstrual function is no reason for giving up lactation. Even pregnancy does not unfit the mother for nursing her child. A child that took the gold medal at a baby show in Boulogne-sur-mer, says M. Budin, was suckled by its mother while she was pregnant. The great lesson of all these considerations is that maternal lactation should not be given up without some very substantial reason.

THE MORAL RESPONSIBILITY OF THE HABITUAL CRIMINAL.

It has long been recognized that the cerebral powers, including under this term all the intellectual, moral, and emotional capabilities and actions of the brain, were apt to differ in the habitual criminal to a greater or less degree from those in the average person of the same age and race. In the beginning this difference was rather unconsciously acknowledged in thought and was ascribed entirely to a perverse moral nature which the criminal could and should have corrected, and it was generally believed that for the crimes and misdemeanors committed in accordance with it he was indubitably and most properly liable. Within the last thirty years much more attention has been paid to criminal psychology, and although this branch of science is as yet only on the threshold of knowledge, its existence has been established and recognized. This subject has been approached from various directions. The writings of Lombroso and his followers, of Baer and others, have drawn attention to the peculiar characteristics of degeneration said to exist

in this class, and whether the statements made by some of these writers and warmly disputed by others can or cannot be verified, medical and scientific attention has been turned toward the existence of physical peculiarities and hence to the consideration of mental peculiarities among the inmates of our prisons and other institutions of correction.

The large and ever increasing number of criminal trials which have occurred within the last few years in which this question of the moral or legal responsibility of the accused has been raised, and the defense of insanity offered, has also had a strong effect in calling the attention both of the medical profession and the public to the general question of moral and legal responsibility, and has justified the present interest in this subject. Moreover, many of our best medical experts have been engaged in the consideration of special cases which bear directly upon the general question. The tendency among some of the most able mental experts to recognize the existence of moral insanity as a separate entity from the ordinary intellectual insanity is viewed with alarm, not only by the unlearned, and to a certain extent by the legal profession, but also by many physicians, and, among these, by many neurologists and alienists. If the plea of moral insanity as a defense can be frequently raised and justified by experts, it is feared that the difficulties in the way of conviction of those who have committed crimes will be greatly increased, and the more numerous and more atrocious the crimes, the more strenuous will be the defense and the more difficult the conviction. While the question of the existence of a pure moral insanity and the possibility and justifiability of its use as a means of defense in criminal trials may be disputed, the interest aroused by this discussion has caused renewed attention to be paid to the psychological problems offered by criminals. It is now generally if not universally admitted by those who have most to do with habitual criminals that their cerebral powers, including in these the intellectual, moral, and emotional, are not the same as those of the average person of their race, age, and sex, and that they have in certain directions less power of control and a lack of certain definite qualities which is not normal or not that of the average individual. It is also admitted that this lack of emotional or moral functions (and

possibly of intellectual) and loss of control power are plainly apparent to those who have the occasion and opportunity to examine into this matter; that in most cases they reach a moderate degree, although of course the degree varies in each individual. If it passes beyond a certain point, the person should be considered insane and treated accordingly. But in spite of the fact that we are inclined to enlarge perhaps too hastily the boundaries of insanity, the very large majority of these persons cannot be considered insane in the sense in which the word is ordinarily used. At the same time they are not mentally normal, and it is probable that their actual criminal responsibility is a diminished one. They have not the power or capability, when once free from restraint, to refrain from crime or misdemeanor, and for this reason they should be kept for the safety of society under perpetual restraint. This restraint need not necessarily be the stone walled, window barred prison, but much better some large place in the country where moderate freedom can be combined with proper surveillance; where they are not let loose on the community, since they are incapable of controlling their actions so as not to be a menace to it, nor are they confined permanently in close quarters with prison discipline. This class should for the safety and comfort of the community be confined or restricted in the manner mentioned, for life or for such long periods as should suffice to render them harmless. They should be recognized and treated as beings but partially responsible for their actions, kindly and firmly, with as much freedom as is consistent with proper restraint, but they should never, while capable of committing crimes, be set free within the community. Settlements, such as those now in use in Massachusetts for the adult feeble-minded and for the chronic insane, might prove the proper means to this end.

WILLIAM N. BULLARD.

SIR CHARLES WYNNDHAM.

It is not often that the opportunity is afforded of paying a visit to a titled and distinguished English medical man for the modest sum of two dollars—the usual fee, we believe, is at least a guinea. Such an opportunity is presented in the professional tour of Sir Charles Wyndham in this country, and for busy physicians we know of no more agreeable relaxation than an evening's en-

joyment of the refined and conscientious art of this eminent confrère. Medical men have achieved distinction in many fields, and there have not been wanting examples of success in dramatic literature. Dr. Schiller's plays constitute a large part of the national literature of Germany. Dr. Smollett wrote several moderately successful plays, and in recent years a distinguished New York laryngologist made an essay in play writing. Perhaps the most notable contemporary achievement of this kind is *Waterloo*, the powerful and pathetic one act sketch by Sir Conan Doyle, so ably presented by Sir Henry Irving. So far as we know, however, examples of physicians forsaking practice for "the buskin'd stage" are rare indeed, and Sir Charles Wyndham's career is unique in the position and success which he has won. He has throughout his long association with the stage retained his interest in his early profession, and as recently as a year and a half ago he delivered a brilliant address at the opening of the London City Hospital. It is not mere fancy, we think, that in some of his rôles there may be traced the influence of his early medical studies. Thus, in the eloquent apostrophe deploring the taint of degeneracy in the second act of *Mrs. Gorrings's Necklace*, there is a suggestion of the broad experience with life and the human sympathies of the true physician. Sir Charles is the possessor of degrees in medicine from the Royal College of Surgeons and Apothecaries' Hall, and is also an M. D. of the University of Giessen. His first appearance on the stage was in this country. He has also acted in German, and fought in the American civil war.

THE CAUSES OF SENILITY.

To those of us who recall Sir James Paget's beautiful likening of senescence to a ripening process it seems harsh to find it ascribed to actual disease. But our friends the pathologists are ruthless in their analysis of its ætiology. At a recent meeting of the Paris Society of Biology (*Semaine médicale*, December 14th) M. Lorand related a number of clinical and experimental facts going to show that it was the result of degeneration of the vascular glands concerned in the maintenance of nutrition, which degeneration was in turn due to certain exhausting agencies, such as excessive childbearing with prolonged lactation, sexual abuses, exogenous or endogenous toxins, chronic infectious diseases, etc.—agencies which in themselves contributed directly to the production of senility. He suggested that by a judicious

use of hygienic measures and organotherapy it might be possible to mitigate some of the symptoms of senility, particularly of the premature type, which, he said, had many points in common with myxœdema.

A SHORTAGE IN SIMPLES.

It is reported that there is a scarcity of various medicinal roots and herbs, especially those of American production, and that in consequence the market prices of those crude drugs have been decidedly raised of late. We may imagine that the activity of the synthetist is driving the herbalist out of business, though it may be that the soil has not recently yielded the usual amount of medicinal plants. Whatever may be the cause of the present deficiency, it is to be hoped that it will be remedied in another season, for we can hardly yet do without the old vegetable *materia medica*.

SPITTING IN THE SUBWAY.

In an editorial in our issue of November 26, 1904, we spoke of the absence of signs in the subway forbidding spitting. It appears that a negro, arrested for that offense on January 2nd, was released by the magistrate on the ground that such signs were absent. Health Commissioner Darlington has since promised, we understand, to order the prohibitory signs placed at once. It is a much needed reform.

THE NEW YORK CITY HEALTH DEPARTMENT.

It is gratifying to observe that in his recent message the mayor speaks in terms of great satisfaction concerning the work of the Health Department during the year 1904. We have no doubt that Commissioner Darlington has fairly earned the mayor's good opinion, and commendation always ought to be bestowed where it has been deserved, not only as a just tribute, but also as an incentive to continued good work.

HALLUX FLEXUS.

A writer in the *Semaine médicale* for December 14th, summarizing an article by M. L. Longuet which appeared in the *Revue d'orthopédie* for September, remarks that M. Longuet proposes the name of hallux flexus for the condition known as hammer toe. If Longuet really first proposed the name, he must have done it long ago, for the term has figured in literature for several years.

News Items.

Society Meetings for the Coming Week:

MONDAY, January 9th.—New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medicohistorical Society (private); New York Ophthalmological Society (private); Medical Association of the Greater City of New York; Society of Medical Jurisprudence, New York; Gynecological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private).

TUESDAY, January 10th.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Medical Union (private) (election); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y.; Newark, N. J., Medical Association (private) (election); Trenton, N. J., Medical Association; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Ky.; Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, January 11th.—Medical Society of the Borough of the Bronx, New York; New York Pathological Society (annual); New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Pittsfield, Mass., Medical Association (private); Philadelphia County Medical Society; Lenox Medical and Surgical Society (private).

THURSDAY, January 12th.—New York Academy of Medicine (Section in Pediatrics); New York Academy of Medicine (Section in Otolaryngology); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society (annual and election); Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, January 13th.—New York Academy of Medicine (Section in Neurology); Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genitourinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, January 14th.—Obstetrical Society of Boston (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending December 31, 1904:

	December 24.		December 31.	
	Cases.	Deaths.	Cases.	Deaths.
Measles.....	163	4	126	6
Diphtheria and croup.....	338	49	302	45
Scarlet fever.....	227	15	206	16
Smallpox.....	1
Chickenpox.....	185	..	87	..
Tuberculosis.....	347	143	434	134
Typhoid fever.....	60	17	52	7
Cerebrospinal meningitis.....	..	17	..	18
	1,321	245	1,207	226

Presbyterian Hospital.—A special offering was requested in the Madison Square Presbyterian Church on Christmas morning for the Presbyterian Hospital, the amount realized being \$3,575.78.

Bellevue Hospital Appointment.—Dr. Edwin Sternberger has been appointed assistant visiting physician in the fourth division of Bellevue Hospital.

Mount Vernon Medical Society.—The annual meeting of the Mount Vernon Medical Society was held December 23rd. Dr. F. W. Shipman delivered the annual address, which dealt with conditions in that city for some time past. The following officers were elected for 1905: Dr. W. S. Fleming, president; Dr. Merriam Myers, vice-president; Dr. Grace G. Prior, secretary; Dr. J. H. Tallman, treasurer; Dr. A. M. Campbell, Dr. T. F. Goodwin, and Dr. E. F. Brush, trustees.

Lincoln Hospital and Home.—Twenty beds were added to the capacity of the Lincoln Hospital and Home, East One Hundred and Forty-first Street and the Southern Boulevard, when the Kathleen Vanderbilt Ward for Children, given by Reginald C. Vanderbilt, was opened on December 26th. Fifteen children were moved into the ward. Mr. Vanderbilt gave \$5,000 for the equipping of the ward, which has been fitted up with the most approved sickroom appliances. The ward is named for Mr. and Mrs. Vanderbilt's daughter, Kathleen.

The Alumni of New York Medical Colleges Dine in Boston.—The New England Alumni Association of the New York City Medical Colleges dined on December 30, 1904, at Young's Hotel, Boston, Dr. J. C. Irish, of Lowell, the president, presiding. Dr. Emerson, of Boston, was toastmaster. There were sixty-six members present, representing Bellevue, the University of New York, and the College of Physicians and Surgeons. There are said to be 250 graduates of these three institutions in Massachusetts, and it is expected that a large association of the alumni there will be built up.

A Luncheon to Dr. Foster.—In commemoration of the twenty-fifth anniversary of Dr. Foster's service as editor of the *New York Medical Journal*, he was tendered a luncheon at the Harvard Club by Mr. A. R. Elliott, President of the A. R. Elliott Publishing Company, on Saturday afternoon, December 31st. Among the guests present were: Dr. Thomas L. Stedman, editor of the *Medical Record*; Dr. Robert W. Taylor, clinical professor of genitourinary diseases; Dr. Reginald H. Sayre, clinical professor of orthopaedic surgery at the University and Bellevue Hospital Medical College; Dr. John Winters Brannon, Dr. E. B. Bronson, Dr. Carl Beck, Dr. C. L. Wheeler, Mr. W. H. Evans, Mr. E. H. Gane, Mr. Caswell A. Mayor, editor, and Mr. T. J. Keenan.

State Hospital for the Insane Wanted in Brooklyn.—A strong plea for the permanent establishment of a State hospital for the insane in Brooklyn borough is made in the annual report of Superintendent O. M. Dewing, of the Long Island College Hospital. The institution now located in Clarkson Street, Flatbush, may go out of existence on October 1, 1905, when the lease of the present site and buildings expires. The report gives in detail the work of the hospital for the year. The number of patients treated was 1,396. The year began with 1,200, of whom 420 were men and 780 women. There were no fatal accidents, no suicides, and no epidemics during the

year, and the two fires which occurred were of trivial nature.

Williamsburg Hospital.—At midnight, New Year's eve, the ambulance service of the Williamsburg Hospital was reestablished and that institution became an emergency hospital for the reception of public patients. The installation of the ambulance service was an important thing to the hospital. Two years ago the hospital was compelled to discontinue its ambulance service because of its expense, and the ambulance was sold to the Bushwick Hospital. An appropriation will be made by the city to cover the expense of the service. The surgeon in charge is Dr. William E. Butler; the house surgeon is Dr. Dorn, and the ambulance surgeon is Dr. Paul Lenox. Mrs. J. M. Walters will remain in active charge of the institution as superintendent.

New York's Death Rate for 1904.—The death rate per 1,000 in Greater New York for 1904 was 20.32, an increase of over 2 per cent. over 1903, when the death rate was 18.18; an unusually low rate. There was a total of 77,985 deaths in the city in 1904, against about 69,000 in 1903. The estimated population is now 3,838,024. There was an increase in the number of deaths from pneumonia and bronchitis. There were 14,518 deaths from those two diseases, while in 1903 there were only 11,550. The report shows that Bright's disease carried off 6,204 persons in 1904, against 5,636 in 1903. There was an epidemic of cerebrospinal meningitis, which killed 1,211, while in 1903 only 271 died from that disease. Including accidents, there were 55,195 violent deaths in 1904, against 4,063 in 1903, and 169 homicides, against 137 in 1903. Perhaps we have figured the population too low. The rate has been as follows in recent years:

1898.....	20.26	1901.....	20.02
1899.....	19.51	1902.....	18.74
1900.....	20.57	1903.....	18.18

The Postgraduate Hospital in Need.—An appeal is made by the directors of the New York Postgraduate Medical School and Hospital, at Twentieth Street and Second Avenue, to the citizens of New York for the sum of \$100,000 independent of the contributions which are made through the hospital association. If the directors can raise this amount an additional \$100,000 has been pledged to them. Dr. D. B. St. John Roosa, president of the corporation, says that the needs of the hospital are great, among them being the extension of the tuberculosis annex in East Nineteenth Street. It has been demonstrated in the dispensary of the Postgraduate Hospital that pulmonary tuberculosis is curable in New York city, through the personal care and proper feeding of poor people so afflicted who are able to obtain none of the luxuries of life either in lodging or food, and who are not always able to secure what may be termed the necessities. More than twenty of these have been cured. There is also pressing need of an ambulance service. The expenses of treatment have been greatly increased by reason of the higher cost of living and of coal. Increased facilities are needed, for the last year's

record shows that while 20,714 was the number of free patients treated in the dispensary and 2,814 occupied free beds, and only two thirds of those who applied could be taken care of.

Academy of Medicine.—The section in pædiatrics will meet on Thursday, January 12th, at 8.15 p. m. Order: Presentation of Patients; A Case of Empyema Apparently Cured Without Operation, by L. E. LaFétra, M. D.; Paper, Standardized Gruels: The Application of the Percentage Principle to Cereal Feeding, by Henry Dwight Chapin, M. D.; discussion by Dr. J. E. Winters, Dr. W. Gilman Thompson, Dr. Henry Koplik, Dr. John Dorning, and others. L. E. LaFétra, M. D., chairman; John Howland, M. D., secretary, 49 East Fifty-third Street.

The section in otology will meet on Thursday, January 12th, at 8.15 p. m. Order: Exhibition of Specimens and Instruments: (a) A New Model for Teaching Otology, by Gorham Bacon, M. D.; (b) Presentation of the Encephaloscope, with Suggestions as to Its Employment, by Fred. Whiting, M. D.; (c) A Case of Epithelioma of the Middle Ear, with Microscopic Slide, by T. Passmore Berens, M. D.; (d) Microscopic Slides from a Case of Epithelioma of the Middle Ear, by W. H. Haskin, M. D.; Papers: (a) A Report of Two Cases of Acute Otitis Media Suppurativa, Followed by Mastoiditis and Meningitis and Caused by the Diplococcus Intracellularis of Weichselbaum, by Gorham Bacon, M. D.; (b) A Report of a Case of Liver Thrombosis, Followed by Infective Arthritis of Both Hips with Spontaneous Dislocations: Operations; Recovery, by W. P. Eagleton, M. D.; (c) Thiosinamine in the Treatment of Tinnitus Aurium, by S. McCullagh, M. D. Emil Gruening, M. D., chairman; W. H. Haskin, M. D., secretary, 42 East Forty-first Street.

PHILADELPHIA.

Personal.—Dr. Henry C. Chapman entertained the members of the American Physiological Society at luncheon at 1.30 p. m. on Thursday, December 29th.

Neurological Society.—The following is the programme of the meeting of the Philadelphia Neurological Society, held November 22nd: Dr. William Pickett, A Case of Arteriosclerosis of the Nervous System; Dr. Charles S. Potts, A Case of Hemiplegia Following Typhoid Fever; Dr. Joseph Sailer, A Case of Tic Convulsif (?) in a Girl of Six, and A Case of Hemiparesis, Muscular Rigidity, and Exophthalmus with von Graefe's Sign; Dr. William G. Spiller and Dr. H. B. Allyn, A Case in Which the First Left Temporal Convolution was Destroyed in an Adult Without Causing Word Deafness; Dr. F. X. Dercum and Dr. Alfred Gordon, A Case of Multiple Spinal Sclerosis, with Remarks Upon the Ætiology of the Affection.

Papers of Interest to Medical Men.—Among the papers read at the meeting of the American Association for the Advancement of Science that attracted considerable attention may be mentioned that of Dr. Edward Anthony Spitzka on

Somatic Anthropology of the Brain of Distinguished Persons, of Individuals of Various Races, and of Criminals. Dr. Spitzka said that the study of criminals by anthropological methods did not necessarily tend to establish a criminal type as maintained by the Lombroso school. Hereafter the classification of criminals must rest upon the observation of individual criminals. The address of Professor George Grant McCurdy, on Prehistoric Surgery; that of Dr. Leon L. Waters, on Food Adulteration; that of Dr. J. B. Smith, on the Breeding Habits of Mosquitoes; and that of Dr. P. S. Maignen, on the Study of Sanitary Science, were also of interest.

Scientific Society Meetings for the Week Ending January 14, 1905.—Monday, January 9th. Section on General Medicine. College of Physicians; Wills Hospital Ophthalmic Society. Tuesday, January 10th. Kensington Branch, Philadelphia County Medical Society; Philadelphia Paediatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, January 11th. Philadelphia County Medical Society; Exhibition Meeting, Pathological Society. Thursday, January 12th. North Branch, Philadelphia County Medical Society; Continuation of Exhibition Meeting, Pathological Society. Friday, January 13th. Northern Medical Association. Saturday, January 14th. West Philadelphia Branch, Philadelphia County Medical Society.

The Health of the City.—During the week ending December 24th the following cases of transmissible diseases were reported:

	Cases.	Deaths.
Malarial fever.....	1	0
Typhoid fever.....	84	8
Scarlet fever.....	52	0
Smallpox.....	1	0
Chick-pox.....	122	0
Diphtheria.....	82	12
Measles.....	7	0
Whooping cough.....	5	0
Tuberculosis of the lungs.....	55	56
Pneumonia.....	73	76
Erysipelas.....	20	2
Puerperal fever.....	1	3
Trachoma.....	3	0

The total deaths for the week were 508 in an estimated population of 1,408,154, corresponding to an annual death rate of 18.76 per 1,000 population. The total infant mortality was 108; 90 under one year and 18 from one to two years of age. There were 39 still births; 24 males and 15 females. The deaths from diseases of the respiratory system (160 cases) continue high. The temperatures have continued low, the thermometer reading 18° on the 22nd. Snow fell on the 24th.

The Meeting of the American Association for the Advancement of Science.—The fifty-fourth annual meeting of the American Association for the Advancement of Science and its affiliated societies, about 40 in number, was held in Philadelphia on December 27, 28, and 29, 1904. The president's address was delivered in the main hall of the new gymnasium of the University of Pennsylvania on Wednesday evening, December 28th, by the Honorable Carroll D. Wright. The subject of Mr. Wright's address was upon the questions of tariff and labor. The meeting was well attended. Among the affiliated societies the proceedings of which will be of special interest to

physicians are the American Physiological Society, which held its seventeenth annual meeting in the medical laboratories of the University of Pennsylvania and in the physiological laboratory of Jefferson Medical College, and the Association of American Anatomists, which held its sessions in the Wistar Institute of Anatomy.

Society Programmes.—At the meeting of the Philadelphia Paediatric Society, held November 8th, the following papers were read: A Note on the Duration of the Prodromal Period in Röteln, by Dr. D. J. Milton Miller; Posttyphoidal Insanity in Children, by Dr. David L. Edsall; Pathological Report of a Case of Hermaphroditism and Sarcoma of the Suprarenal Gland, by Dr. C. Y. White and Dr. Verner Nisbet. Dr. George W. Norris exhibited a patient with endocarditis.

The following was the programme of the meeting of the Pathological Society of Philadelphia at its regular meeting, held November 10th: Dr. D. J. McCarthy, Congenital Deformities, with Presentation of a Case of Deformity of the Extremities of a Dog; Dr. J. Funke, Erosive Gastritis; Dr. M. H. Fussell, Malignant Endocarditis; Dr. David L. Edsall, Decidua Malignum.

At the meeting of the section in ophthalmology of the College of Physicians, held on Tuesday, November 15th, Dr. Alexander Duane, of New York, read a paper by invitation on The Practical Application and the Relative Value of the Tests Used in Examining the Eye Muscles, with Demonstration of Methods.

The following was the programme of the meeting of the section in general medicine of the College of Physicians, held November 14th: Report of a Case of Cancer of the Esophagus Simulating Thoracic Aneurysm, by Dr. J. A. Scott; The Pharmacological Action of Mercury, Its Influence on Autolysis, by Dr. D. L. Edsall and Dr. Caspar W. Miller (by invitation); Some Clinical Observations on Cirrhosis of the Liver, by Dr. Alfred Stengel; Hæmorrhagic Diathesis in Bright's Disease, a Report of Two Cases, by Dr. David Riesman.

The following programme was offered at the monthly meeting of the section in otology and laryngology of the College of Physicians, held November 16th: Dr. Wendell C. Phillips, of New York, Inflammatory Manifestations in the Upper Air Passages Due to Malarial Plasmodium; Dr. W. G. B. Harland, Verruca Obstructing the Nostril in a Colored Child; Dr. G. B. Wood, A Case of Antral Neurosis; Dr. J. K. Knorr (by invitation), A Case of Papilloma of the Larynx; Dr. Walter Roberts, A Case of Malignant Adenoma of the Larynx; Dr. A. W. Watson, A Case of Sarcoma of the Antrum Ten Years After Operation.

The American Physiological Society.—The following was the programme of the American Physiological Society at the meeting held last week:

Dr. V. C. Vaughan, A Contribution to Cell Chemistry; Dr. P. A. Levene, The Autolysis of Animal Organs; Dr. A. S. Lovenhart, Some Observations on the Catalytic Decomposition of Hydrogen Peroxide by Organ Extracts; Dr. G. H. Parker, Ciliary Reversal in Metazoans; Dr. G. M. Meyer and Dr. W. J. Gies, A Study of the Coloring Matters in the Purple Pitcher Plant (*Sarracenia purpurea*);

Dr. P. B. Hawk, A Study of the Conditions Following the Establishment of the Eck Fistula in Dogs; Dr. A. Mandel (by invitation), On Paralactic Acid; Dr. F. P. Underhill, Certain Aspects of Experimental Diabetes; Dr. E. T. Reichert, A Second Coagulation of the Blood Due to a Substance Not Identical with Fibrinogen and Coagulable by Saturation with Neutral Oxalate; Dr. F. C. Busch and Dr. C. Van Bergen, Further Results in Suprarenal Grafting; Dr. J. J. R. Macleod and Dr. H. D. Haskins, A Method for the Estimation of Carbamates in Animal Fluids; Dr. J. J. R. Macleod and Dr. H. D. Haskins, Some Remarks on the Chemistry of Carbamates; Dr. W. Koch, On the Origin of Kreatinin; Dr. L. B. Mendel and Dr. O. E. Closson, On the Elimination of Creatinine; Dr. O. Folin (by invitation), The Nitrogen of Urine; Its Distribution Among the Four Important Constituents.—Urea, Ammonia, Uric Acid, Kreatinin; Dr. F. P. Knowlton (by invitation), A Case of Tumor of the Floor of the Fourth Ventricle with Cerebellar Symptoms, in a Cat; Dr. E. R. Posner and Dr. W. J. Gies, A Further Study of Protogin; Dr. O. Klotz (by invitation), On the Presence of Soaps in the Organism in Certain Pathological Conditions. Preliminary Communication; Dr. E. P. Lyon, On the Theory of Geotropism in Paramoecium; Dr. W. Koch, On Psychic Secretion; Dr. W. B. Cannon, Observations on the Alimentary Canal After Splanchnic and Vagus Section; Dr. W. T. Porter, Further Observations on the Physiology of the Vasomotor Centre; Dr. Y. Henderson and Dr. M. McC. Scarborough, The Volume Curve of the Mammalian Ventricle; Dr. Y. Henderson, The Events Within the Heart; Dr. J. Erlanger, An Instance of Complete "Heart Block" in Man; Dr. G. P. Clark, A Method of Measuring and Recording Maximum as Well as Minimum Blood Pressure in Man; Dr. F. S. Lee, Some of the Physical Phenomena of Muscle Fatigue; Dr. J. R. Murlin (by invitation), Gelatin as a Substitute for Proteid in the Food; Dr. T. B. Osborne and Dr. L. B. Mendel, Further Studies on Ricin; Dr. T. Sollmann, The Effect of Isotonic Solutions on the Kidney; The Effect of Blood on the Blood Vessels of the Kidney; Dr. S. J. Meltzer and Dr. J. Auer, On the Rate of Absorption from the Muscular Tissue; Dr. E. M. Houghton, The Pharmacology of Ethyl Salicylate; Dr. F. S. Lee (for Dr. H. Emerson), Demonstration of a New Water Manometer; Dr. G. P. Clark, An Adjustable Tracheal Cannula for Artificial Respiration; Dr. W. T. Porter, An Exhibition of Physiological Apparatus; Dr. E. P. Lyon, Demonstration of Apparatus; Dr. A. P. Brubaker, Demonstration of Apparatus.

GENERAL

Baby Born in the Chicago Pesthouse.—A girl was born in the Chicago pesthouse on December 20th of a mother suffering from smallpox. She was vaccinated immediately and it is hoped to save her.

Hospital of the Good Shepherd, Syracuse, N. Y.—The Syracuse Hospital of the Good Shepherd has received a New Year's gift of \$50,000 from William B. Cogswell, of that city, who has at various times contributed large sums to its support.

St. Peter's Hospital, Albany.—Dr. Arthur W. Elting has been appointed to the staff of St. Peter's Hospital, Albany. On account of the resignations of Dr. J. V. Hennessey and Dr. Charles E. Davis, there will be a reorganization of the staff.

The Jefferson County, Ky., Medical Association, at its tenth annual meeting on December 20th, at Louisville, elected the following officers: President, Dr. William Cheatham; vice-president, Dr. John Moran; treasurer, Dr. Sidney Meyers; secretary, Dr. E. O. Witherspoon.

Massachusetts General Hospital.—The will of E. M. Codman has been filed at Salem, Mass., and by its terms the family fortune goes to Harvard

University and to the Massachusetts General Hospital. The value of the estate is estimated at about \$1,250,000. The fortune is divided in equal shares between the two institutions.

South Carolina State Hospital for the Insane.—At the annual meeting on December 30th of the board of regents of the South Carolina Hospital for the Insane an assistant superintending physician was elected in the person of Dr. H. H. Griffin, who is the son of Dr. P. E. Griffin, who was for thirteen years superintendent of the institution.

A \$5,000,000 Hospital for Boston Assured.—The gift of \$5,000,000 under the will of Peter Bent Brigham for the purpose of founding a hospital for people in indigent circumstances in the city of Boston was sustained by the United States Circuit Court of Appeals on December 7th, in the case of Herbert F. Brigham vs. the Peter Bent Brigham Hospital *et al.*

The Delegates to Panama Delayed.—A heavy fog settling down on the St. Charles River at 3 p. m., December 27th, prevented the sailing of the steamship *Athos* for Colon, Panama, with a party of 38 delegates and visitors who were to attend the Pan-American Medical Congress at Panama, January 3rd, and the later meeting of the American Public Health Association at Havana.

Gift to London, Eng., Hospitals.—It is reported that Lord Mountstephen, formerly president of the Canadian Pacific Railroad, has presented to the King's Hospital Fund as a New Year's gift \$500,000 in Argentine funding bonds and \$500,000 in Buenos Ayres water works bonds, yielding an annual income of \$55,000. His lordship, it is further said, has received a personal letter of thanks from the king.

The Medical Society of the County of Clinton, N. Y.—The annual meeting of this society will be held in the Grand Jury Room at the Court House, in Plattsburgh, N. Y., on Tuesday, January 10, 1905, at 1.30 p. m. Programme: President's address, by Dr. Silver; Injury to the Cranium and Its Contents, with Report of Cases, by Dr. Ransom; Prophylaxis in Pregnancy and Labor, by Dr. Rogers; Obituary Notice of Dr. L. C. Dodge, by A. W. Fairbank; Some Experiences in Appendicitis, by C. W. Arthur, M. D. D. S. Kellogg, secretary.

A Memorial Folder to Dr. Osler.—We have received from the *Maryland Medical Journal* a memorial folder of Dr. William Osler, who leaves Baltimore next spring to accept the appointment of regius professor at the University of Oxford. Attention is called to Dr. Osler's impress upon medical journalism as a factor in professional progress. It was he, the memorial says, who infused new life into the *Journal*, and his interest in its welfare was never lost, no matter how exacting were the demands of his profession. The memorial contains a poem on Dr. Osler, written by Mr. Thomas O. Clark, and comments by several publications upon the announcement of Dr. Osler's intention to sever his connections with the Johns Hopkins Hospital.

Milwaukee County, Wis., Medical Association.

—At the annual meeting of the Milwaukee County Medical Association held on December 9th, the following officers were elected: President, Dr. J. W. Coon; vice-president, Dr. R. G. Teschan; treasurer, Dr. Joseph Kahn; secretary, Dr. A. W. Gray; censor, Dr. E. Copeland. The election of delegates to the meeting of the State association was deferred to the next meeting.

St. Louis Medical Society.

—At the annual meeting of the St. Louis Medical Society, held in its hall in the Y. M. C. A. building, December 17th, the following officers were elected for the year: Dr. Frank L. Henderson, president; Dr. John C. Moffit, vice-president; Dr. Thomas A. Hopkins, recording secretary; Dr. Charles J. Orr, corresponding secretary; Dr. R. M. King, treasurer; Dr. B. M. Haypes, member of board of censors.

Maryland's First Tuberculosis Hospital.

About 50 patients suffering with tuberculosis are comfortably housed and being cared for at the first public hospital for consumptives in Maryland, which is situated not far from Bayview Asylum, near Baltimore, on a beautiful hill, near an old farm house, and commands a splendid view of the surrounding country. The farm house has been transformed into quarters for five nurses, who will be in attendance. Sunlight and pure air are the methods of treatment that have been aimed at especially.

Recent Graduates of Rush Medical College,

Chicago.—The degree of doctor of medicine was conferred upon the following seventeen graduates at the quarterly commencement exercises of Rush Medical College on December 19th: Paul Raymond Badger, Joseph Louis Baer, William Rudolph Boose, William W. Bradley, James Henry Fairchild, Charles Emerson Ingbert, Arthur Edward Johnson, Martin Ingeman Olsen, Joseph Rowland Morrell, George Albert Landes, Carl August Ostling, Romney Moore Ritchey, Max Jason Salamon, George Senn, Harry Francis Sloane, Frank Hastings Stevenson, Norman E. Williamson.

The Denver Academy of Medicine was formally opened on December 19th at 1434 Glenarm Street. The officers of the association are: President, Dr. Henry Sewall; secretary, Dr. Edward Jackson; directors, Dr. W. W. Grant, Dr. G. M. Macomber, Dr. Thomas H. Hawkins, Dr. W. A. Jayne, and Dr. Edward Jackson. The qualifications for membership are that the applicant must be a reputable physician who has been practising at least three years and who has been a resident of Denver for at least two years. The society will subscribe for about 150 medical journals, and will add, from time to time, to the library the best books known on medical subjects. There is a large hall in connection with the meeting room, and in this it is designed to hold all meetings of medical societies.

Medical Society of the Missouri Valley.

—In response to a cordial invitation from the Jackson

County Medical Society, the semiannual meeting of the association will be held in Kansas City, Thursday, March 23, 1905. Those desirous of presenting papers should send their titles to the secretary not later than February 1st. Papers will appear upon the programme in the order in which they are received. An invitation has been extended to the presidents of the State associations within the territory embraced by the Missouri Valley, and to the profession in general, and an interesting and profitable meeting is expected. Any one not a member of this association should send in an application to the secretary at once. Initiation, one dollar; annual dues, one dollar. S. Grover Burnett, M. D., president, Kansas City, Mo. Charles Wood Fassett, M. D., secretary, St. Joseph, Mo.

Statement of Mortality in Chicago for the Week Ending December 24, 1904, compared with the preceding week and with the corresponding week of 1903. Death rates computed on United States Census Bureau's estimated midyear populations of 1,932,315 for 1904 and of 1,873,880 for 1903:

	Dec. 24, 1904.	Dec. 17, 1904.	Dec. 26, 1903.
Total deaths, all causes.....	548	509	514
Annual death rate per 1,000.....	14.83	13.77	14.29
By sexes—			
Males.....	293	293	310
Females.....	252	216	204
By ages—			
Under 1 year.....	94	96	87

After three weeks of unusually low December mortality the seasonal winter increase has set in sharply. The 548 deaths from all causes reported during the week represent a 7.6 per cent. increase over the previous week and nearly 4 per cent. more than the corresponding first winter week of 1903. In themselves none of the important causes of death shows any increase sufficient to create alarm; consumption only six more, cancer seven more, diphtheria three more, pneumonia nine more, smallpox four more, and whooping cough three more than the previous week. But the revelations of the Chicago laboratory indicate a serious increase of atmospheric impurity, only temporarily checked by the snowfall. The germs of all the air borne diseases are rife and the influenza bacillus or grippé germ is endemically prevalent in many sections of the city. The health department renews its warning against all unnecessary exposure to those suffering from any of the contagious and infectious diseases, especially from pneumonia and influenza.

Pain in Floating Kidney,

By TH. TUFFIER.

Floating Kidney.—Tuffier describes two cases, in one of which the pain was very severe with exacerbations, in the other very slight. He considers pain as variable in existence, intensity, localization, radiation, severity, form, and intermittence, and believes that from these variations indications can be drawn regarding prognosis and treatment. He divides the pain into two general forms, constant and intermittent. The constant form is centred in the lumboliliac region, whence it radiates in many directions, is rarely acute and is increased by pressure. It is rarely met with in children, usually in adults, appearing as a rule slowly and progressively. It is frequently associated with pains in the liver, intestines, stomach, uterus and annexa, from which it must be distinguished. The intermittent form presents two varieties, one simply a dragging sensation with radiations to the lateral parts of the thorax, very rarely toward the abdomen; the other the pains due to an intermittent hydronephrosis.

The Bloodless Reduction of Congenital Dislocation of the Hip Joint,

By J. GOURDON.

Bloodless Reduction of Congenital Dislocation of the Hip Joint.—Gourdon describes with illustrations Lorenz's method of reduction, which is quite familiar, but adds nothing new. He says correctly that the criterion of the efficacy of the method is its adoption by all orthopædic surgeons.

November 16, 1904.

Pyelonephritis During Pregnancy,

By E. BOCHARD.

Pyelonephritis During Pregnancy.—Bochard reports a case of pregnancy in which signs of pyelonephritis appeared first on the right side, later on both. In spite of all medicinal treatment the patient's physical condition constantly grew worse. As a last resort premature labor was induced, after which the threatening symptoms immediately abated.

SEMAINE MEDICALE.

November 0, 1904.

The Rôle of Heredity in Renal Pathology,

By CASTAIGNE and RATHERY.

The Rôle of Heredity in Renal Pathology.—Castaigne and Rathery conclude from their investigations that the theory of renal heredity rests upon a clinical, an anatomopathological, and an experimental basis. The clinical result shows that mothers with nephritis have children with kidneys which are susceptible to infections and intoxications and that they occasionally succumb during the first few hours or days of life. Autopsies upon such cases have demonstrated that extensive nephritis was present. Experimentation confirms the results observable in human histology. Chronic nephritis has been produced in female animals which have subsequently been impregnated and their offspring

has presented the same disease, either in the form which is like that which has been observed in the human fœtus, or with superficial lesions, such as would be expected to cause albuminuria. The blood serum and the amniotic fluid of females suffering with nephritis contain substances which are poisonous, and these substances are transmitted in abundance to the offspring.

November 16, 1904.

Idiopathic, or Congenital Dilatation of the Colon,

By CHEINISSE.

Idiopathic, or Congenital Dilatation of the Colon.—Cheinisse cites various authors to show that this condition is not so very rare. While it is more frequent in young infants it is not unknown in adults and especially in the aged. While it is frequently fatal it is not necessarily so. It may be caused by a stricture of the rectum or the sigmoid flexure, the dilatation being above the obstruction. While the walls of the colon are usually hypertrophied, especially the muscular coat, they are sometimes atrophied. The mucous membrane in the very young is seldom diseased. In those who are older it is sometimes ulcerated. The dilatation may be so great as to require puncture of the intestine to relieve the gas which has resulted from retention and putrefaction of fecal matter. Large enemata are recommended and careful regulation of the diet. If these fail, surgical interference will be required. Anastomosis will usually be only a palliative remedy; resection may be required to produce permanent benefit.

November 23, 1904.

1. Pathological Rôle of Poisons in the Intestines,

By CHARRIN and LEPLAY.

2. Tubal Abortion,

By LEJARS.

1. **The Rôle of Poisons in the Intestine.**—Charrin and Leplay conclude from their investigations that in the normal condition of the digestive tube innumerable poisonous substances are constantly present. In addition there are toxic substances, the diastases, for example, which are indispensable to the nutritive changes of the body. The organism has various means for defending itself, and the tendency of disease is to break down such means of defense. If the views of pathogenesis advanced by the authors are true they signify that general therapeutical measures are inadequate. They indicate that the enemy is to be attacked directly and also that the means of defense must not be broken down. Normal organic products are often morbid and the physiological digestive secretions themselves are such at times. Before destroying them it is necessary to allow them to accomplish their proper functions and maintain intact all the means of defense with which the body is provided.

2. **Tubal Abortion.**—Lejars observes that tubal rupture with all its dramatic surroundings is the accident connected with tubal pregnancy which is most often observed. Tubal abortion is almost as frequent. Of 100 cases of tubal pregnancy in which an operation was performed at the

Moabit Hospital in Berlin 48 were tubal abortions and 50 were ruptures. Tubal rupture before the eighth week of impregnation usually implies involvement of the uterine third of the tube, and is usually primary. If the pregnancy involves the ampulla, the death of the ovum and hæmorrhagic effusion during the first two months are not followed by immediate rupture, the tubal sac remaining intact with the possibility of a secondary rupture, or else of subsequent results which may be equally bad. Very important is the diagnosis of early tubal abortion. It may be suspected when the menses are delayed and after a few days or weeks come with abundant flowing, which is prolonged far beyond the usual period. The uterus is usually soft and somewhat enlarged, and a small sensitive mass will be present on one side or the other or in Douglas's cul de sac. The symptoms may disappear entirely within a few days, but more frequently there will be trouble of a serious character in the future.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE

1. Migration of *Ascarides* from the Intestines Into the Pancreatic Duct, Followed by an Interstitial Pancreatitis, By GIOVANNI GHEDINI.
2. On the Cardiopulmonary Changes Met with in Typhoscolioses, By ANTONIO PISANI.
3. Anthropological Considerations on a Case of Bilateral Hereditary Plantar Keratoma, By MARIO COSTANZO.
4. Action of the Muscular Plasma of Healthy and Immunized Animals Upon the Bacillus of Koch, By R. B. PALLIERI.

1. **Ascarides Producing Pancreatitis.**—Ghedini reports the case of a child who died after a symptom complex resembling that of basilar meningitis. The child had complained for some days before death of a severe recurrent pain in the abdomen, which was found sensitive on pressure. There was also obstinate hiccough. The autopsy showed that the intestines were full of ascarides, some of which had passed into the pancreatic duct and had penetrated into the pancreas itself, especially into the head of that organ where they could be found on section. The pancreas was found to be the seat of an interstitial pancreatitis. This case is an extremely rare example of the migration of ascarides. They have been found not infrequently in the liver, but seldom in the pancreas.

ROUSSKY VRATCH.

November 20, 1901

1. The Treatment of Congenital Dislocation of the Knee, By G. I. TURNER.
2. The Operative Treatment of Empyema (*To be continued*), By S. S. GRIGOLAV.
3. On the Question as to Dysentery in Manchuria (*Concluded*), By V. G. KORETCHENSKI.

1. **Congenital Knee Dislocation.**—Turner describes a case of congenitally dislocated knee in a young woman, twenty years of age. Congenital dislocation of the knee is a much less frequent deformity than congenital dislocation of the hip.

Within the past few years, however, an increasing number of cases of congenital knee dislocations has been reported, and the interest in this subject has been enhanced by recent improvements in the methods of orthopædic surgery. The diagnosis of this condition does not offer great difficulties and it is usually made out at an early age, in contrast to congenital hip dislocations, which are often not noticed until the child has reached an advanced age. The cause of congenital knee dislocations is an abnormal position of the fetus in utero, with the legs extended and the soles of the feet facing the child's face. No characteristic anatomical lesions are found in these cases. The ends of the bones are fully developed but do not show any mutual adaptation. On the other hand, the crucial ligaments are poorly developed, the semilunar cartilages are very thin and the articular surfaces flattened. In the case reported the patient walked on the ends of her thighs, and her knees were completely turned forward. She was unable to contract the flexor muscles of the knee, and to straighten out her limbs. This was prevented by a contraction of the quadriceps muscle. There was, in addition, club foot on both sides. The muscles of the thighs and legs were perfectly well developed, and the Röntgen rays alone showed the condition of the bones about the knee joint. The operation consisted of removing the crucial ligaments, and the cartilages, and in so fashioning the ends of the bones with chisel and sharp spoon that there was formed a rounded femoral end which fitted into a hollow in the upper end of the tibia. The cartilaginous surface of the patella was removed and the patella fitted into an artificial hollow in the femur. The joint was then closed and put in plaster of Paris. At a subsequent operation the deformity on the other limb was remedied in a similar manner. The tendon of the quadriceps was first cut, and the leg straightened. The club foot was corrected on both sides by appropriate tenotomies. The result was that the patient could walk without supports, but the right knee was ankylosed, while the left showed a mobility of thirty degrees, with a slight bend in the wrong direction.

3. **Dysentery in Manchuria.**—Koretchenski submits a very complete report on dysentery among the Russian troops in Manchuria, with special reference to the effects of Shiga's and Gabritchewsky's serum for the treatment of this disease. He treated in all seventy cases of dysentery of various degrees of severity. The doses of this serum varied from 20 to 110 c.c. at one injection, and the amounts administered to a single patient varied from 20 to 360 c.c. No drugs whatever were employed for a while, until the dejections had become purely fecal in character. During the catarrhal stage, when the stools were still fluid, bismuth, salol, and the like, were used. In some cases, in addition, irrigations with weak solutions of potassium permanganate were also employed. Koretchenski concludes that the serum undoubtedly presents a valuable means of treating dysentery. In the mild cases 20 c.c. of the serum aborted the disease. In the more severe cases 40 or 60 c.c. were required, and then the dose had to be repeated sometimes. In very severe cases he gave 100 c.c. at first and repeated the dose

when necessary. In almost all cases it was necessary to repeat the dose when the infection was severe. Unfortunately, there were cases of dysentery which had been neglected or which were so severe from the start that the serum did not have any effect. The same has been noted in the use of antitoxine in diphtheria. There is no question that the serum shortens the duration of the disease, and is superior to all other remedies hitherto applied. No relapses were noted after the use of the serum, and in no case did an acute dysentery become chronic.

1. Ligation of the Femoral Artery in Hunter's Canal.
By S. I. KALANTAROFF.
2. Secondary Cesarean Section in a Case of Narrow Pelvis,
By V. N. ORLOFF.
3. Empyema and Its Operative Treatment (*Continued*),
By S. S. GIGOLAFF.
4. On Septicæmia in Early Childhood,
By S. E. OSTROFFSKY.
5. A Case of Situs Viscerum Inversus,
By N. A. ZIEVAKINE.

1. Ligation of the Femoral in Hunter's Canal.

—Kalantaroff publishes some interesting researches concerning the technics of ligation of the femoral in the femoropopliteal canal. This ligation he considers to be the most difficult one in the lower extremity. The lines of incision indicated for it by various authors, including Malgaigne, Poupert, Richer, etc., all have some defect, and only Quaine (? Quain) gives the proper directions for this incision. The chief difficulty in finding the vessel lies in the fact that the insertion of the sartorius, which serves as a landmark, is subject to variations. It is a common error to take the internal head of the quadriceps femoris for the sartorius and thus the operator fails to find the artery. The author investigated the anatomical relations of Hunter's canal in sixty cadavers, and came to the conclusion that the best method for this ligation is as follows: After the patient has been placed in the proper position for the exposure of Hunter's canal, first find the sartorius. This is done by measuring a distance of thirteen cm. from the tubercle of the adductor muscle, a point which indicates where the sartorius muscle in the average person crosses the line of incision. The incision should be made from four to five cm. in length, on the right side from above downward to the point marked, and on the left side from this point downward. The incision is made along the line indicated by Quaine, namely, one drawn from the middle point between the anterior superior spine and the symphysis, down to the tubercle of the great adductor muscle. This indicates the course of the femoral artery. By measuring thirteen cm. along this line we are able to find the sartorius, without which we cannot find the artery.

2. Two Cesarean Sections in a Patient With Narrow Pelvis.—Orloff relates the case of a woman, aged twenty-seven years, who had an absolutely contracted pelvis due to rickets, which necessitated a Cesarean section in 1901, from which the patient recovered uneventfully. A second

operation was performed in the same woman in 1904. The interesting feature in this case was, that the ovaries and tubes had been left intact during the first operation, at the special request of the patient herself, in spite of the assurance that she could not bear children normally. Although in both operations the uterus was incised during the first stage of labor, there was a prompt and efficient contraction of the uterine vessels, and the loss of blood was not greater than during normal labor. The author thinks that the best rule as to the time when such operations should be undertaken is, that if the woman is otherwise healthy and there is no tuberculosis or other imperative reason for hurrying, the section should be performed when true uterine contractions have begun, thus insuring an arrest of hæmorrhage without much trouble. He believes that drainage into the vagina by means of a gauze strip is useless in these cases, and that it only facilitates infection.

4. Sepsis in Infants.—Ostroffsky relates the case of an infant, aged fourteen days, in whom he observed the development of a septicæmia at the acme of which streptococci appeared in the blood. At the autopsy no infection was found to have taken place through the umbilicus, and the only possible portal of entry seemed to be a slight injury to the right ankle. The treatment proved ineffectual but the author did not employ antistreptococcus serum.

MEDICAL RECORD.

December 31, 1904.

1. On What Lines is the Treatment of Malignant Disease Advancing,
By ROBERT ABBE.
2. Problems Relating to Simple Ulcer of the Stomach,
By BEVERLEY ROBINSON.
3. The "Yolk Cure" in the Treatment of the Undeveloped,
By HEINRICH STERN.
4. Trachoma,
By ALBERT C. BARNES.
5. The Present Attitude Regarding the Treatment of Prostatic Hypertrophy,
By MARTIN W. WARE.

1. Malignant Disease.—Abbe holds that the treatment of malignant disease has made notable advances recently in three directions, viz., (1) in the recognition of the *principle* that carcinoma and sarcoma are primarily of local origin. This makes the cure almost certain when very early operation is done. (2) In recognizing the enormous value of increasingly extensive operation in advanced cases—widening the field of skin removal and lymphatic dissection. (3) In establishing the value of radiotherapy. Apart from these we have to record attempts to utilize serum therapy—antitoxine—and tissue metabolism by oophorectomy (Beatson's method) and thyroid extract administration. Serum therapy is still of undetermined value. The author has performed oophorectomy eight times in five years for malignant disease of the breast. In all but one case retrograde changes occurred and life was prolonged. Ultimately all the patients but one died of cancer. Phototherapy is of no value in malignant disease. There remain for consideration the Röntgen rays, the ionized rays, and the rays from radium. The author is of the opinion

that radium promises the best results of any of these forms of treatment.

2. **Ulcer of the Stomach.**—Robinson makes a strong plea for continuing to consider ulcer of the stomach a medical disease. If perforation occurs the condition is unquestionably surgical, and it is also a surgical condition if repeated hemorrhages endanger the patient's life. Statistics show that with careful medical attention most cases of simple ulcer will recover. Surgical treatment has a high mortality and "cures" are often temporary.

3. **The "Yolk Cure."**—Stern defines his yolk cure thus: "Under 'yoke cure' I understand a dietary regimen in which the greater portion of calories is yielded by the yolk of the hen's egg, and in which the latter forms the only fatty substance. Besides this *rigid* 'yoke cure' we may speak of *modified* forms of the same. A modified 'yoke cure' is a dietary regimen which is either (a) not a succession of 'yolk days' (that is 'when days on which yolks do not preponderate in the diet are inserted'), or (b) when the yolks although contained in the diet in a certain amount, do not furnish the bulk of the calories and are not the sole representatives therein of the fatty ingesta. In a majority of instances a modified 'yolk cure' will be found to offer certain advantages over the strict regimen when the patient's alimentary tract is in good condition and after subsidence of the acute decline, or after the patient has started to gain in body weight. Moreover, the 'yoke cure,' modified according to the individual needs and desires and remodified from time to time in accordance with the changed conditions in the organism is the only means by which a yolk diet may be continued for many months and even for years." The paper discusses the scientific basis for this form of treatment and gives in detail a sample menu destined for a consumptive weighing 110 pounds, whose normal weight ought to be 149 pounds.

5. **Prostatic Hypertrophy.**—Ware holds that in uncomplicated cases prostatectomy is best done by the perineal route. A calculus, vesical hemorrhage or a large diverticulum call for the suprapubic method. On the other hand, the perineal route is one of absolute necessity, when there is suppurative inflammation of the prostate or diseased conditions of the urethra, such as stricture or perineal extravasation. In well-to-do patients operation may, with safety, be delayed until the symptoms become urgent. In the poor it is best to operate at once.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

7. Double Radial Rupture of the Iris,

By S. C. AYRES.

8. Two Additional Cases of Sympathectomy for Glaucoma,

By WILBER B. MARPLE.

9. Blastomycosis of the Eyelid,

By WILLIAM H. WILDER.

10. Subjective Refraction,

By JOHN A. TENNEY.

11. The Effect of Pilocarpine Hydrochloride in Strychnine Poisoning,

By S. J. MELTZER and W. SALANT.

12. Idiopathic Gangrene in the Young,

By M. L. STEVENS.

13. The Resistance of the Peritonæum. Illustrative Case,

By CHESTER M. ECHOLS.

2 and 3. See this *Journal*, Vol. LXXX, page 133.

4. **Lupus Erythematosus.**—Hartzell has treated five cases of lupus erythematosus by the following method: (1) Large doses of quinine internally; (2) locally repeated freezing of the diseased areas with ethyl chloride. The parts should be kept frozen for from five to eight minutes at each sitting and treatment should be repeated every two or three days for an indefinite time. Small superficial areas may heal by the end of six weeks or two months. From his limited experience with the method the author is inclined to look upon it as an extremely useful one in the treatment of this obstinate affection.

5. See this *Journal*, Vol. LXXX, page 331.

6. **Chorea.**—Hollopeter has treated from forty to fifty cases of chorea by the method to be described and asserts that the duration of the disease was reduced to six weeks from three months. Method: Place the child in a warm bath (90° to 96° F.) and keep it there, immersed to the neck, for at least one or two hours twice a day. At the end of each bath gentle superficial massage should be practised. A nap follows each bath.

8. **Sympathectomy.**—Marple reports two cases of sympathectomy for the relief of glaucoma. In all he has observed five similar cases. From his personal observation he concludes: (1) Sympathectomy is not indicated in acute inflammatory glaucoma. (2) If the operation is ever justified it is in cases of chronic simple glaucoma. (3) This method of treatment has not, probably, a very brilliant future.

11. **Pilocarpine in Strychnine Poisoning.**—Meltzer and Salant refer to a case of strychnine poisoning in which recovery was claimed to have been due to the use of pilocarpine hydrochloride hypodermatically. They have tested the probability of this assertion by means of experiments upon rabbits and frogs. They are of opinion not only that the pilocarpine did not save the child's life, but also that in cases of strychnine poisoning pilocarpine is positively contraindicated.

12. **Idiopathic Gangrene.**—Stevens reports the case of a girl of 13 years who died of gangrene

of both feet and legs. No autopsy was obtained. There was no apparent cause to account for the gangrene.

BOSTON MEDICAL AND SURGICAL JOURNAL.

1. The Ultimate Results of Cauterization of the Lower Turbinate, with Therapeutic Suggestions Based Upon Histological Findings, By J. L. GOODALE.
2. Standard Records of the Leucocytes in Normal Blood for Reference in Clinical Work, By HENRY F. HEWES.
3. An Improved Method of End to Lateral Intestinal Anastomosis. A New Mattress Stitch, By ALFRED H. GOULD.
4. Bacterial Counts of Boston's Milk Supply, By HIBBERT WINSLOW HILL and FRANCIS HENRY SLACK.
5. Isolation Methods and Precautions in Contagious Disease, By F. P. DENNY.
6. A Case of Suspected Homicide Proved to Be Suicide by Strychnine, By F. J. CANEY.

1. Cauterization of the Lower Turbinates.—

Goodale gives first the results of a histological examination made into a series of cases which had been previously cauterized for swelling or hypertrophy of the lower turbinates, and which had reported later with a recurrence of nasal obstruction. With these results as a basis he formulates the following rules for the proper cauterization of the turbinated bodies: (1) If the object is to contract a relaxed or distended mucous membrane, we should endeavor to reach the submucous and deeper layers where the lymph spaces and blood vessels are chiefly situated, producing at the same time the minimum amount of disturbance to the mucous membrane itself. This result is best attained by deep linear applications, as narrow as possible, of chromic acid, or of the galvanocautery, or by submucous cauterization, which is an admirable and most effective method. (2) If we seek to diminish the amount of nasal fluid, as in certain forms of excessive post-nasal secretion, we may advantageously sacrifice a certain number of canaliculi in the basement membrane by broad, superficial applications to a definite area of the septum and lower turbinates posteriorly. (3) In the event of recurrence of enlargement after cauterization, we should remember that a more impervious and resistant mucous membrane probably exists, together with a proportionately greater amount of connective tissue than originally was present, and that consequently each subsequent cauterization is less likely to bring about contraction of the parts. Under such circumstances, it is probably best to dispense with further cauterizing and proceed immediately to the excision of a definite amount of obstructive tissue.

2. The Estimation of the Leucocytes.—

Hewes details a rapid clinical method of approximately determining the total leucocyte count from the ordinary stained specimen. In order to use the method one must first construct a standard table of blood counts. This table differs according to the microscope used. Essentially the method consists in counting the number of leucocytes in one hundred fields of a stained specimen and then comparing

these figures with those of the standard table. Those interested in hæmatology should consult the original paper, for the method, while easy in practice, is difficult to describe.

3. End to Lateral Anastomosis.—Gould's paper is the first of a series of four articles dealing with proposed changes in surgical technics. The changes proposed have been worked out upon animals and upon the cadaver. The present paper describes a method of joining the end of the small intestine to the side of the large. The technical details, for which originality is claimed, are: (1) Method of trimming the invaginated gut. (2) Method of placing the first layer of sutures. (3) A new mattress stitch. (1) The small gut at its free end is split opposite the mesentery for one and one half inches, and the corners are then rounded off. By this expedient the future anastomotic opening will be larger than the calibre of the small intestine. (2) The first line of sutures is a continuous over and over stitch applied by the aid of guide sutures, much on the plan of the Connell method of end to end anastomosis. (3) The new mattress stitch is a cross between a Lembert suture and a Halstead stitch. The loop of the Halstead stitch is placed near the cut edge and the ends are rotated through one hundred and eighty degrees before being introduced into the opposing edge of the gut in the Lembert fashion. When this stitch is tied the cut edges of the gut are inverted and peritonæum is opposed to peritonæum. The article is illustrated.

MEDICAL NEWS.

December 31, 1904.

1. The Effect of Hysterectomy on the Sexual Function, By HIRAM N. VINEBERG.
2. The Difficulties of Anæsthetization and Their Correction, By VICTOR C. PEDERSEN.
3. Hyperacute Melancholia: Report of a Case, By ROBERT N. TODD.
4. The Finsen Method, By MILTON FRANKLIN.
5. The Antiseptic Treatment of the Puerperal Woman, By LOUIS KOLIPINSKI.
6. Cerebral Palsies in Children, By J. M. AIKIN.

1. **Hysterectomy.**—Vineberg discusses the effect on the sexual function of hysterectomy performed on the adult woman. It is nil. "The conclusion I would draw from my own experience and from a study of the literature on the subject is that whatever other effects the removal of the uterus and ovaries may have upon the female human economy, it has little or none upon her sexual feelings."

2. **Anæsthetization.**—Pedersen reviews in very great detail the chief difficulties which may arise during the administration of an anæsthetic. One point made in the paper may be worth repeating. The diagnosis between pure respiratory and pure circulatory cyanosis is easily made by noting the capillary circulation. This is most readily done by compressing the finger nails and noting the more or less rapid return of the expelled blood.

4. **The Finsen Method.**—Franklin describes in some detail six types of Finsen lamp. Most space is devoted to the Finsen-Reyn lamp, which is

the one best adapted to private practice. As to the value of the Finsen method in the treatment of lupus vulgaris the author has this to say: "I think that the Finsen method when properly practised, and this necessitates the employment of suitable apparatus free from glass and of sufficient power, is superior to all known procedures for the treatment of lupus vulgaris. This opinion is the result of a close observation of the results obtained at the only place where the method has been properly employed. The use of the x ray has been too limited to warrant the positive assertion that it is a specific in lupus. The cases that have been positively cured by the Finsen method are almost without number, while those cured by the x ray are few and scattered, and their authenticity shrouded in uncertainty. It may be that we shall finally find a valuable therapeutic agent in the high frequency currents, but in the meantime we have the ultraviolet treatment of Finsen."

5. **The Puerperal Woman.**—Kolipinski is in favor of treating all puerperal women with large boric acid douches repeated three or four times a day.

AMERICAN MEDICINE

December 31, 1901

1. Ideal Method of Removing the Vermiform Appendix,
By HOWARD A. KELLY.
2. Tuberculosis of the Kidney, Ureter, and Bladder,
By J. M. BALDY and EDWARD A. SCHUMANN.
3. Primary Sarcoma of the Stomach: A Report of Three Cases,
By JOHN A. SIPHER.
4. The Reflexes in the Diagnosis of Nerve Lesions, Due to Trauma,

5. On the Cause of Death in "Operated Cases" of Intestinal Perforation Occurring in Typhoid Fever,
By J. H. ANDERSON.
6. Polyneuritis Complicating Typhoid Fever with Unusual Localizations,
By ALFRED GORDON.

1. **Amputation of the Appendix.**—Kelly reviews the history of amputation of the appendix and describes about a dozen methods for treating the stump. He then proposes a new method. This requires a special crushing and cooking forceps. "The appendix is exposed, and the meso-appendix is tied off. A circular suture of fine silk is then laid around its base, about a centimetre distant, but not drawn up. The appendix is then grasped at its base with the forceps and crushed, while just beyond the forceps (distally) it is seized with an ordinary artery forceps to prevent the escape of its contents. Paquelin's cautery is now used to amputate the appendix between the two forceps, when it is laid aside in the grasp of the artery forceps. The crushing forceps, which is now to be converted into a cooking, sterilizing, sealing iron, is carefully isolated by tucking dry gauze under each blade, so as to lift the end of the forceps up on a cone, away from all contact with the cæcum. The next step, which is the most important one, is to keep the red hot point of the cautery slowly travelling up and down the groove in the crushing forceps for from 40 to 60 seconds, so as to burn off every vestige of the stump, and at the same time to heat the forceps so thoroughly that the narrow ribbon of

crushed appendix in its grasp becomes converted into a translucent gristle-like substance, in which the lumen of the appendix is completely destroyed. The lumen is so effectually obliterated that it never gapes. The final step is the tightening of the purse string suture, and the inversion of the cooked base, after which the serosa is carefully united over the whole with another row of fine silk sutures. I have cut off a little piece of the cooked tissue in seven cases, and dropped it into a test tube containing an agar medium, and in but one case was any growth obtained."

2. **Tuberculosis of the Kidney.**—Baldy and Schumann report a case of tuberculosis of the kidney, ureter, and bladder. The diseased kidney and ureter were removed at operation. The case is of interest chiefly because the condition was mistaken for tubal disease. There were no kidney or bladder symptoms.

3. **Sarcoma of the Stomach.**—Sipher reports three cases of primary sarcoma of the stomach which were studied in the pathological department of the Western Reserve University. Up to 1902 Howard found 61 similar cases on record. The author has been able to find records of five other cases since this date; there are therefore a total of 66 such cases on record.

4. **Nerve Lesions Due to Trauma.**—Upson calls attention to the very great aid that may be derived from a study of the various reflexes in an attempt to reach a correct diagnosis, specially in cases where it may be to a patient's advantage to mislead the physician; as in suits for damages. The author gives his estimate of the value of the following reflexes: Knee jerk, Achilles jerk, Babinski reflex, and ankle clonus. The claim of impotence, as a result of injury, is at times made. Direct proof is out of the question. The following points if carefully noted will at times clear up all doubts. The cremasteric reflex, the virile reflex, and the papillas along the posterior edge of the glans penis, if all of them are present, exclude organic impotence due to nervous shock or nervous disease, in men who present no evidence that the spinal cord is cut or compressed. Of these, the virile reflex should be given the first place. To obtain it, press the forefinger against the patient's perineum, and with the other hand pinch the mucous membrane of the glans penis. At each pinch a muscular contraction is plainly felt in the perineum, due to the action of the erector penis muscle. The absence of this reaction is the strongest presumptive evidence of impotence.

5. **Perforation in Typhoid.**—Anderson emphasizes his belief that one of the causes of death following operations for typhoid perforation is the toxæmia which arises from the contents of the paralyzed bowel. The author recommends that the ileum be emptied of its contents and the bowel irrigated either through the perforation itself or through a special incision. He has employed this method in nine cases. The results obtained satisfy him that the expedient is a useful one.

3. Ethyl Chloride as an Anæsthetic in General Practice, By H. HILLIARD.
4. Acute Lymphocythæmia, By L. S. DUDGEON.
5. Two Cases of Severe Cranial Injury, By W. D. CHAPMAN.
6. A Case of Congenital Hypertrophic Stenosis of the Pylorus in the Adult, By A. E. MAYLARD.
7. Notes Upon Two Renal Cases, By W. H. CLAYTON-GREENE.
8. A Case of Anencephalous Monster, By H. BEATTIE.
9. Appendicitis and Pregnancy: Notes of a Case with Operation and Recovery, By H. A. LEDIARD and R. E. SEDGWICK.

1. **Operative Treatment of Constipation.**—Lane considers the causation, pathology, symptoms, and treatment of the changes in the gastrointestinal tract which result from and are associated with the habitual overloading of the large bowel. Dilatation with corresponding lengthening is a marked feature in certain portions of the intestine, the most marked examples being the cæcum, the transverse colon, and the rectum. Fixation with a corresponding atrophy of the muscle coats of the wall of the intestine is especially marked in every portion of the large bowel except the bulk of the cæcum and the entire transverse colon. This fixation is brought about by a gradual process of anchoring the outer aspect of the upper part of the cæcum, of the colon, and the mesosigmoid and sigmoid flexure to the peritonæum lining the adjacent abdominal wall. In a few cases the sigmoid flexure, instead of becoming shortened, atrophied, and fixed is elongated, hypertrophied, and abnormally movable. Rotation of this elongated, overloaded loop gives rise to complete intestinal obstruction—the so called spontaneous volvulus of the sigmoid flexure. A perfectly normal sigmoid, according to the author, cannot suddenly become twisted so as to form an immediate obstruction. The same applies to volvulus of the cæcum. Adhesions form between the appendix and the adjacent portion of the iliac fossa: when the cæcum is loaded it excites a strain on the proximal portion of the appendix and flexes it abruptly at the lower limit of its adhesions. Thus the appendix is occluded, its secretions are dammed up, and an inflammation of varying intensity is produced. The constant recurrence of appendiceal obstruction may lead to the formation of a calculus. Now the chief factor in all these changes is an overloading of the cæcum and ascending colon. The erect position habitually assumed during the greater part of the twenty-four hours is a great factor. Even in defecation, as usually practiced, the cæcum is driven downwards and forwards into the true pelvis; whereas in the squatting position enormous pressure is afforded by the forcible apposition of the thigh and abdomen. In many of these cases of chronic constipation the kidneys are immobile, from

the constant pull on them. A second factor in the displacement of the kidneys is the absorption of fat due to the toxæmia. The poisoning from absorption of toxic material also manifests itself by increasing staining of the skin, and by marked mental depression. As already mentioned obstruction of the appendix is a very common concomitant of the alteration in the form and mechanics of the cæcum. In the treatment of the condition the author has had considerable success in opening the abdomen and dividing all constricting bands and adhesions, and subsequent careful attention to the proper functioning of the bowel. But when the alterations have proceeded too far, he divides the ileum about five inches above the cæcum, and makes an anastomosis with either the sigmoid flexure or the rectum, thus throwing the cæcum and colon "out of circuit." In a very few cases subsequent excision of the cæcum and colon may be required. But usually the patients rapidly regain their lost flesh, strength, and health.

3. **Ethyl Chloride.**—Hilliard is strongly in favor of ethyl chloride as an anæsthetic, providing its dangers are recognized. It is portable, of stable composition if it is kept in the dark, easy of administration, acts rapidly, and provides a narcosis of several minutes after the removal of the inhaler, which narcosis is quiet and sleep-like. But if complete muscular flaccidity is required the anæsthetic must be pushed to the limit of safety. The writer prefers Braine's modification of Onnsby's inhaler. The same preparation of the patient is necessary as for ether narcosis. Almost any position of the patient is safe, but the recumbent posture is best for children. Do not have the head either too far backward or forward. A good average dose for an average adult is five cubic centimetres. It is better to give a full and rapidly induced anæsthesia than to admit air and economize the drug. Ethyl chloride should not be administered in the following conditions: diseases of the larynx; inflammatory lesions or tumors in, or adjacent to, the respiratory passages; goitre; all conditions giving rise to urgent dyspnoea; and in long operations.

4. **Acute Lymphocythæmia.**—Dudgeon reports the case of a man aged thirty-seven years, who when first seen was intensely anæmic: the spleen and liver were both enlarged, and there was a high degree of oral sepsis. There was no glandular enlargement. He had been ill about two months. Blood examination showed the red corpuscles to be about two million to the cubic centimetre, and the leucocytes 43,000: of the leucocytes 96 per cent. were lymphocytes. Two weeks later the red corpuscles had sunk to just under one million, and the leucocytes had risen to almost half a million. There was a marked relative increase in the number of the large lymphocytes. Cultures from the blood showed the presence of the staphylococcus albus.

6. **Congenital Hypertrophic Stenosis of the Pylorus in the Adult.**—Maylard reports the case of a man aged thirty-one years, upon whom the operation of posterior gastrojejunostomy was performed for a supposed simple stricture of the pylorus. The patient died eight months later and

at the autopsy the stricture was found to be due to hypertrophy of the muscular coat of the pylorus, which hypertrophy extended well out into the stomach. Taking into consideration the absence of any indication of old ulceration, the uniformity of the pyloric constriction, the gradual tapering off of the hypertrophied gastric wall from the pylorus toward the body of the stomach, the absence of any malignant element, and the age of the patient, the author classes the case among those rare examples of congenital hypertrophic stenosis occurring in the adult.

BRITISH MEDICAL JOURNAL.

December 17, 1904.

1. Remarks on the Indications for Operative Interference in Diseases of the Stomach, By R. SAUNDREY.
2. The Diagnosis and Surgical Treatment of Certain Cases of Chronic Indigestion, By G. BARLING.
3. Duodenal Ulcer and Its Treatment, By D'A. POWER.
4. The Germ Cell Theory of Cancer, By A. S. GRÜNBAUM.
5. Report No. LXXXIX to the Scientific Grants Committee of the British Medical Association. The Nature of the Malformations of the Rectum and Urogenital Passages, By F. WOOD-JONES.

1, 2, 3. **Surgery of the Stomach.**—Saundrey states that operative interference is imperative in: (a) Impermeable stricture of the œsophagus; (b) perforated gastric ulcer; (c) subphrenic abscess; (d) tumor in the region of the stomach with vomiting and other symptoms of pyloric obstruction. He admits the reasonableness of surgical interference in gastric hæmorrhage, but so far he has never found it necessary to operate, all of his cases having recovered in the end. In an uncomplicated case of gastric ulcer there should be no question of surgical assistance. It is very rare that gastric ulcer does not improve under treatment, and the author has never seen an uncomplicated case result fatally. In duodenal ulcer operative interference for repeated bleedings should be tried. In dilatation of the stomach a distinction must be made between primary or idiopathic, and secondary or obstructive dilatation, as it is in the latter only that surgical aid is required. Where obstruction exists, whether from external pressure, adhesions, growth, hypertrophy, or spasm, a cure can be effected only by surgical means. A physician should not persist in merely palliative treatment when gastroenterostomy will bring about a complete cure. The clinical indication for this operation is stasis, which is of more importance than the size of the stomach or the existence of dilatation. In idiopathic dilatation without stasis the balance of opinion is against operation. Operations upon neurasthenic subjects should be avoided as far as possible. Hour glass stomach is by some thought to be merely an exaggeration of the physiological division of the organ into fundus and antrum pylori, and calls for surgical treatment only when it gives rise to symptoms of obstruction and stasis. Hyperchlorhydria is not infrequently associated with stasis and pyloric stenosis or spasm. Wherever stasis is present gastroenterostomy is indicated: but if it is a pure neurosis surgical interference is uncalled for. Neither chronic gastritis, atonic dyspepsia, nor gastralgia in itself requires surgical treatment. The presence of cancer of the

stomach clearly indicates operation: the real difficulty is that of early diagnosis, the nature of the case being often only recognized too late. Barling tells us that there is a group of cases of digestive derangement which call for surgical treatment. Excluding perforation these are: 1. Chronic gastric ulcer, frequently relapsing despite proper dieting and rest. 2. Hæmorrhage from gastric ulcer, where the bleeding is profuse and quickly repeated, or where there is never a great loss but one which is often repeated. 3. Mechanical obstruction to the emptying of the stomach from pyloric stenosis, hour glass contraction or external adhesions. 4. Ulcer or stenosis of the duodenum. The operative measures required for the relief of these various conditions may be: 1. Excision of the ulcer. 2. Pylorodiosis or stretching of a narrowed pylorus. 3. Pyloroplasty or gastroplasty, division of the stricture, and its widening by a special method of suturing. 4. Gastroanastomosis, or the formation of a function between stomach and jejunum, stomach, and duodenum, or between the distal part of the stomach and the proximal in certain cases of hour glass contraction of the organ. The first three operations have only a very limited application: gastrojejunostomy is the operation of election in the large majority of cases. The death rate will be, in the hands of those accustomed to perform the operation, about five per cent. Power's paper on duodenal ulcer is based upon the observation of seven cases which he reports in tabular form. He tries to show that: (a) Duodenal ulcers are not very uncommon. (b) So far as he has seen them, duodenal ulcers are single and occur more often in men than in women. (c) Duodenal ulcers may perforate and cause acute symptoms or they may heal and by cicatrization lead to symptoms of chronic duodenal obstruction. (d) The sequelæ of a healed ulcer may be so remote that the symptoms are mistaken for those due to cancer of the pylorus, and the patient is allowed to drift from bad to worse under the erroneous notion that he is bound to die. (e) There is no means of recognizing the existence of a duodenal ulcer, in a great many cases, until it perforates or until the results of its cicatrization become manifest. (f) The treatment of duodenal ulceration consists (1) in the direct suture of a perforated ulcer, the prognosis being less favorable than in similar cases of perforation; (2) the performance of gastrojejunostomy in cases of dilated stomach due to duodenal constriction, the prognosis being the most favorable of all the conditions for which this operation is done at the present time.

4. **Cancer.**—Grünbaum states that the explanation of the genesis of malignant growths has been brought nearer by two notable investigations. They are (1) the proof by Beard, of the morphological continuity of the germ cells; and (2) the discovery by Farmer, of heterotype mitosis in malignant tumors. Given the cells of the potential growth, it seems not improbable that the toxine of a parasite, the short stimulus of a trauma, the long continued stimulus of chronic irritation, or the chemical conditions of disordered metabolism, might suffice to turn loose their energies, and thus one or all the alleged causes in turn have their share.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of Wednesday, December 14, 1904.

The President, Dr. ROLAND G. CURTIN, in the chair.

The Differential Diagnosis and Treatment of Acute Pelvic Peritonitis Associated With Gonorrhœal Salpingitis.—Dr. BROOKE M. ANSPACH, in this paper, drew attention to the fact that while pelvic peritonitis of gonorrhœal origin was best treated expectantly during the acute stage, it occasionally bore a close resemblance to acute inflammation of the vermiform appendix, in which the expectant plan of treatment would be dangerous. The diagnosis was based largely upon the mode of onset, the history of the patient, and the presence of gonorrhœa. Bimanual palpation in an initial attack of acute pelvic peritonitis due to the gonococcus must be negative. This was because of rigidity of the abdominal walls and the slight structural change found early in these cases. After rest in bed, the use of salines, and hot applications to the abdominal wall, the symptoms subsided in from three to ten days. At this time examination was painless, the structural lesions were plainly evident, and an operation should be performed. In case the expectant plan failed and the case progressively became worse, in view of the possibility of general peritonitis, no time should be lost in opening the abdomen. Several cases were given in detail.

Dr. CHARLES P. NOBLE considered Dr. Anspach's paper so sound that there was little to say in discussion. Increased experience led him to expect less from conservatism in gonorrhœal salpingitis than formerly. He agreed with Dr. Anspach in his views regarding an operation in acute gonorrhœal peritonitis. He recalled having operated twice in the acute stage. In one case the peritonitis was quite diffuse; the patient recovered. In the other there was a large abscess to the left of the sigmoid. This patient also recovered. One of the cases in which the result of conservatism had been good was that of a young woman who had acquired gonorrhœa, and peritonitis resulted in an extraperitoneal abscess. He had operated in the acute attack and drained per vaginam, and to his surprise the patient made an excellent recovery. The woman had since been married and borne children. Unless the patient was a young woman, it was Dr. Noble's rule to take out both tubes, the uterus, and the ovaries.

Dr. JOHN G. CLARK said that the reason why the gonococcus did not produce general peritonitis was because its chief habitat was the mucous membrane. As soon as the gonococcus left the Fallopian tubes and enters Douglas's cul-de-sac, the peritonitis was merely toxic, due to the toxins of the gonococcus. He believed it unwise to operate during an attack of gonorrhœal peritonitis. Illustrative of this, he cited a case in which

the symptoms had increased in severity and the question arose whether there was simply a gonorrhœal peritonitis or involvement of the tubes and ovaries. An operation was done, the tubes and uterus being removed and the ovaries left. Subsequently the woman had a large abscess involving the ovary. Opening of the incision and further drainage were necessary.

He emphasized the necessity of a close diagnosis and the importance of knowing when to wait until the acute attack had passed and when not to wait, but to operate for a more lethal type of infection. For the past few years it had been Dr. Clark's effort to conserve all tissue possible, because the usual individual who contracted gonorrhœa was a young woman. He felt that the conservative policy in some instances worked well, but in the majority of cases badly.

Dr. EDWARD MARTIN said that his experience in this class of cases in recent years had been only as long as was requisite to transfer the patient to the hands of a competent gynecologist, but that in earlier days he had seen a good many such cases which had ended in prompt recovery under conservative treatment of the acute attack.

Dr. NOBLE had never seen a patient die of gonorrhœal peritonitis.

Dr. ANSPACH called attention to the fact that in a good many of these cases of acute pelvic peritonitis due to gonorrhœa not much was gained by bimanual examination. While all the cases were correctly diagnosed, had he not had the history and seen the associated signs of the gonorrhœal infection, he could not have formed much of an opinion.

The Significance of Abulic Symptoms in Cases of Mental Disease.—Dr. ROBERT H. CHASE, superintendent of the Friends' Asylum for the Insane, Frankford, read a paper with this title (to be published).

Dr. CHARLES K. MILLS said he believed papers of this kind of great use, even to those not particularly interested in mental and nervous affections, and that if there were presented to the profession more frequently the methods of studying mental symptoms there would be given a better insight to the cases of insanity and cases not so regarded. He considered the subject a large one from the standpoint of the alienist.

On the Advisability of a National Department of Public Health and a Medical Cabinet Officer.

—Dr. T. H. EVANS said this subject had been suggested by the late Dr. William Pepper. The writer favored the move as a means to centralize and render more effective the many interests of the country that were medical. The supervision of education of children, so as to suit individual tastes, needs, and abilities, is indicated. Physicians ought to control all matters which concerned the physiological welfare of the citizen. The care of criminals, once apprehended by the law, belonged properly to medicine. Colonies for mental and moral degenerates, if established, would materially reduce crime. The physical defects of children should be understood as productive of later immorality or conducive to it, if suitable education did not intervene. The educa-

tion and licensing of practitioners of medicine and surgery, in the opinion of the author, belonged to a central office, whose executive head should have a place in the cabinet of the President.

Dr. EDWARD MARTIN felt that in the main all were in accord with the views of Dr. Evans. The question of education, however, he thought should be a matter of State control. In regard to criminals, he thought the matter of imprisonment not so much one of punishment as of protection for the rest of the community, and that too much leniency had been allowed on a basis of mental defect. The idea of centralization he thought was applicable to the subjects of sanitation and prophylaxis, particularly against contagious diseases and in regard to such general subjects as water pollution. The establishment of a national board he thought was hoped for by all physicians.

Dr. CHARLES K. MILLS believed that much could be accomplished by the establishment of a central health department of some description. It was, however, a question more difficult of solution than would seem to physicians, who had only the physician's side of the subject before them. Personally he would be very glad to see the medical profession represented in the cabinet, and believed much good might come from such a movement. It might, however, be better if a department of science were created with bureaus of different sorts, including a national bureau of health, which would take cognizance of matters of this sort. The great advantage of such an office would be the unifying of methods of procedure concerning matters of health in all parts of the country. With such a national organization much might be accomplished in matters of quarantine, the pollution of rivers, the registration and examination of physicians, and such questions as physicians had the first right to consider. Those who had committed crime should, if their mental and physical health was a matter of question, receive that attention which was often not given to them, both before and after trial and after conviction. Such questions as the care of the insane, the care of epileptics, and the commission of crime by the young would receive the more humane attention if there were some method of regulating their consideration and if that method were, in part at least, national and centralized.

Dr. WILLIAM S. WADSWORTH thought it appropriate that the Philadelphia County Medical Society should recognize the needs of the community for a larger, broader, and more intelligent handling of State medicine. He thought it not possible for men unversed in medical science to take care of the lives of human beings. Various questions which should come under the head of such a national executive department mentioned by Dr. Wadsworth were the adulteration of foods, the study of sewage, the protection of life on railroads and in factories, child labor, the importation of hides and such materials, and the quality of drugs and patent medicines. He regarded as highly desirable the presence of a medical man in the cabinet.

Book Notices.

Beiträge zur Behandlung putrider Zahnwurzeln unter spezieller Berücksichtigung der Anwendung schwacher galvanischer Ströme (Elektrosterilisation). Von FR. E. ZIERLER, an der kais. russ. Universität Dorpat appr. Zahnarzt, ehem. Assistent am zahnärztl. Institut und Klinik für Zahn- und Mundkrankheiten in Warschau. Würzburg: A. Stuber's Verlag (C. Kabitzsch), 1905. Pp. 53.

The author describes in this brochure his experience with the electric current in sterilizing infected pulp canals of teeth. The question of pulp sterilization is one of considerable importance in view of the local disturbances to the retentive apparatus of the tooth which may follow infections of the surrounding tissues by the invasion via the pulp canal of the root, and because of the more remote disturbance which these avenues of entrance for pathogenic bacteria may cause, as, for example, infection of the antrum of Highmore and the accessory sinuses of the face, tuberculosis of the cervical lymphatics, and many other suppurative processes, as well as alveolar necrosis, which have their origin from that source.

After discussing the usual methods of pulp canal sterilization the author reports that he has obtained the best results from the use of a five per cent. aqueous solution of iodine applied for thirty minutes, and by formaldehyde in a two per cent. aqueous solution, for fifteen minutes. He gives no account of the testing of sodium dioxide solution or of the efficiency of the Kalium Natrium method introduced some years ago by Schreier, of Vienna, both of which latter have a most satisfactory clinical record.

Believing many of the methods in use to be ineffectual in the destruction of certain bacteria of the putrid dental pulp, especially the spores of the *Bacillus gangrena pulpæ* discovered by Miller, of Berlin, and described at length by Arkövy, of Budapest, the author was led to study the efficiency of the electrical current as a means for securing sterilization of the pulp canal. For that purpose he tested the sterilizing effect of the current upon an infected Petri plate and found that a circular area of about one and one quarter inch in diameter around the anode was rendered completely sterile. Stab cultures made in the sterilized area showed subsequent growth, as also did cultures in bouillon made from particles of the same sterilized surface.

The principle upon which the electrical sterilization is effected is that of the electrolytic action of the current upon the sodium chloride contained in the fluid, whereby chlorine is liberated at the anode, and the sterilizing therefore depends upon the activity of chlorine as a germicidal agent.

The author uses a platinum-iridium needle as an anode and makes the cathode application upon the arm by means of a dishshaped terminal. He finds that a current pressure of from thirty-five to forty volts and a flow of three milliamperes should be kept up for about ten minutes. He describes certain necessary apparatus for the control of the current, which may be either the street current or that of a Leclanché battery of thirty-two cells. These are,

however, technical details not germane to the principle of the method under consideration.

Great stress is laid upon the necessity for gradually increasing the current to the maximum flow advised. The allegation made for the method by the author is the rapidity with which complete sterilization of a root canal can be effected.

The method as above outlined and described at length in Zierler's monograph is not new. Not less than eight years ago, when cataphoresis was suggested as a means for obtunding sensitive dentin, the possibility of effectually sterilizing a root canal and pyorrheal pockets about the teeth was generally discussed, and considerable experimentation resulted not only in the use of platinum-iridium anodes, but that of anodes of amalgamated zinc and of copper. These latter base metal anodes were suggested by Dr. Morton, of New York, for the reason that when they were used in saline solutions the electrolytic action of the current resulted in the formation of mercury, zinc, or copper salts respectively which were driven deep into the tissues cataphoretically and there exhibited their well known germicidal properties. The method has not received the attention which it deserves, and the present work of Zierler should serve to revive interest in its possibilities and develop its more general use.

The Art of Compounding. A Textbook for Students and a Reference Book for Pharmacists at the Prescription Counter. By WILBUR L. SCOVILLE, Ph. G., formerly Professor of Theory and Practice of Pharmacy in the Massachusetts College of Pharmacy; Member of the Committee of Revision of the United States Pharmacopoeia. Third Edition, Revised and Enlarged. Philadelphia: P. Blakiston's Son & Co., 1904. Pp. 339. (\$2.50 net.)

In this new edition considerable fresh matter is to be found, as, for example, a chapter on tablets in which is treated the manufacture of compressed and triturate tablets. This will be found useful for reference by practising physicians as well as by dispensers. A new chapter on sterilization and disinfection treats the subject in a rather elementary fashion, but the author prepares us for this by explaining that it was arranged to meet the needs of pharmacists. The work has been improved and extended in other directions, so that it stands to-day as one of the best sources of information regarding a branch of the pharmacist's art with which physicians should be better acquainted.

Manual of Physiological and Clinical Chemistry. Second Edition, Revised and Enlarged. By ELIAS H. BARTLEY, B. S., M. D., Ph. G., Professor of Chemistry, Toxicology, and Pædiatrics in the Long Island College Hospital; Author of Medical and Pharmaceutical Chemistry. With 47 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1904. Pp. 181. (\$1.00.)

Intended chiefly as a textbook for the use of students, this handy little volume of Dr. Bartley's seems to us to amply fulfill its purpose. The author's many years of experience in the teaching of those branches of chemistry usually taught to

medical students have singularly qualified him for the preparation of a textbook concerned with the application of the science of chemistry to the diagnosis and treatment of diseased conditions. In the new edition much new matter and many new processes are included, some of the latter being original with the author. The manual is embellished with useful and well selected illustrations.

A Laboratory Guide in Elementary Bacteriology. By WILLIAM DODGE FROST, Ph. D., Assistant Professor of Bacteriology, University of Wisconsin. Third Revised Edition. New York: The Macmillan Company; London: Macmillan & Co., Limited, 1903. Pp. xiii-395. (\$1.60.)

The objective of this book is to give adequate directions to the student for the performance of certain fundamental exercises in bacteriology. The various bacteria are studied in groups, so as to emphasize the similarity between closely related forms as well as minute but important differences. Migula's system of classification is used. Opposite pages have been left blank for notes and drawings, so that a permanent record may be kept. The title page has the date of publication 1903, while the copyright states that it was published in October, 1904.

BOOK AND MAGAZINE NOTES.

The Century Company has in press a new novel by Dr. S. Weir Mitchell, the title and subject of which have not been announced. Dr. Mitchell will be 75 years old in February, but he is still actively engaged in literary work and considers his new novel the strongest story he has ever written.

Sherlock Holmes has been galvanized into activity again, so lovers of the adventurous will take new lease of life. Sir Arthur Conan Doyle's book will be called "The Return of Sherlock Holmes," and will be brought out early in February and illustrated by Charles Raymond Macaulay. In the thirteen new tales which the book contains, Sherlock is said to be even more astute, brilliant, and astounding than ever. The same mystery, the same impending perils, the same hairbreadth escapes that thrilled in former volumes are present in this one, and the reincarnated Sherlock offers even more complex problems than of yore and unravels them with even greater deftness.

BOOKS, PAMPHLETS, ETC., RECEIVED.

The Surgery of the Diseases of the Appendix Vermiformis and Their Complications. By WILLIAM HENRY BATTLE, F. R. C. S., Surgeon to St. Thomas's Hospital, Formerly Surgeon to the Royal Free Hospital, etc., and EDRED M. CORNER, M. B., B. C., F. R. C. S., Surgeon in Charge of Out Patients to St. Thomas's Hospital, Assistant Surgeon to the Great Ormond Street Hospital for Sick Children, etc. Chicago, 1905: W. T. Keener & Co. Pp. 208. [\$2.50 net.]

Manual of Antenatal Pathology and Hygiene; the Embryo. By J. W. BALLANTYNE, M. D., F. R. C. P. E., F. R. S., Edin., Lecturer on Midwifery and Gynecology, Medical College for Women, and Surgeons' Hall, Edinburgh; Examiner in Midwifery in the University of Edinburgh. Edinburgh, 1904: William Green & Sons. Pp. xix-697. [21s. net.]

Bacteriology and the Public Health. By GEORGE NEWMAN, M. D., F. R. S. E., D. P. H., Formerly Demonstrator of Bacteriology in King's College, London; Medical Officer of Health of the Metropolitan Borough of Finsbury, etc. Third Edition, Illustrated. Philadelphia, 1904: P. Blakiston's Son & Co. Pp. xx-497.

The Chemical Synthesis of Vital Products and the Interrelations Between Organic Compounds. By RAPHAEL MELDOLA, F. R. S., V. P. C. S., F. I. C., etc., Professor of

Chemistry in the City and Guilds of London Technical College, Finsbury; Member of the Faculty of Science, University of London, and of the Teachers' Registration Council. Vol. I. Hydrocarbons, Alcohols, and Phenols, Aldehydes, Ketones, Carbohydrates, and Glucosides, Sulphur and Cyanogen Compounds, Camphor and Terpenes, Coloring Matters of the Flavone Group. London, 1904: Edward Arnold. Pp. xvi-338. [\$6.00 net; by mail, \$6.22.]

One Hundred Years of Publishing (1804-1904). A Brief Historical Account of the House of William Wood & Co. Illustrated. New York, 1904: William Wood & Co. Pp. 29.

Clinical Hematology. A Practical Guide to the Examination of the Blood with Reference to Diagnosis. By JOHN C. D'ACOSTA, JR., M. D., Demonstrator of Clinical Medicine, Jefferson Medical College; Chief of Medical Clinic and Assistant Visiting Physician, Jefferson Medical College Hospital, etc. Second Edition, Revised and Enlarged. Containing 9 full page Colored Plates, 3 Charts, and 64 Other Illustrations. Philadelphia, 1905: P. Blakiston's Son & Co. Pp. 501. [\$5.00 net.]

Miscellany

Officers of the American Physiological Society.

—The American Physiological Society has elected the following officers for the coming year: President, Professor W. H. Howell, Johns Hopkins University; secretary, Professor Lafayette Mendel, Yale; treasurer, Professor W. B. Cannon, Harvard.

American Society of Naturalists.—One of the largest audiences gathered to hear the discussion on The Mutation Theory of Organic Evolution, which was scheduled to be held in the Auditorium of Houston Hall, Philadelphia, at 3 p. m. on Wednesday, December 28, 1904, under the auspices of the American Society of Naturalists. The audience was so large that it was necessary to adjourn to the operating room in Dental Hall. The subject was discussed by D. T. MacDougal, of the New York Botanical Garden, from the standpoint of plant breeding; by W. E. Castle, of Harvard University, from the standpoint of animal breeding; by Dr. E. G. Conklin, of the University of Pennsylvania, from the standpoint of cytology; by W. B. Scott, of Princeton University, from the standpoint of palæontology; by Dr. Thomas Dwight, of the Harvard Medical School, from the standpoint of anatomy; by Liberty H. Bailey, of Cornell University, from the standpoint of taxonomy; and by W. M. Wheeler, of the American Museum of Natural History, from the standpoint of ethnology.

Report on Radiotherapy.—Kienbock, in *Archives of the Röntgen Ray*, for November, 1904, observes that every living tissue is subject to pathological change under the action of the Röntgen rays which is not due to a static electrical effect. It consists in degeneration and necrosis, and young and proliferating cells are especially affected. This degeneration can be detected by the microscope within a few hours after a single exposure of medium duration. A longer exposure causes inflammatory changes accompanied by lesions of the walls of the blood vessels, after a definite lapse of time. The intensity of

this dermatitis depends upon the dose of the radiation. The effects depend upon the penetration of the rays to different depths, which vary with the character of the tube employed, soft, medium, or hard. The action does not extend beyond the limits of the parts exposed to the rays. During the exposure there is no visible change in the tissue; the microscopical changes begin after a few hours, the clinical symptoms of dermatitis after one, two, or three weeks. In radiodermatitis five periods may be distinguished: those of latency, ascendance, acme, descendance, and after a period of many months, lesions may occur. The greater the dose of rays at one sitting the shorter the period of latency, the stronger the reaction, and the longer the duration of the dermatitis. There may be four degrees of exposure:

1. Latency of three weeks. No superficial inflammation of the skin, temporary loss of hair, shrinking of lupus nodules, exacerbation of pre-existing inflammation.
2. Latency of two weeks. Erythema, swelling lasting one or two weeks, loss of hair.
3. Latency of ten days. Redness, vesicles, excoriation and exudation, resolution in three or four weeks.
4. Latency of five to eight days. Discoloration, the commencement of necrosis, demarcation and ulceration, followed by scarring after six weeks or longer.

One year or eighteen months after a dermatitis of the second degree, the characteristic atrophy of the skin with telangiectases of the skin may occur. These late symptoms invariably follow an exposure of the third degree.

The author uses a coil which gives a spark of 15 or 20 inches, a mercurial or an electrolytic break, with a regulating tube maintained at a medium degree of hardness. The maximum light of the tube is used, the tube being brought as near to the affected spot as possible, the exposure being limited to a few minutes. The surrounding skin is protected by a lead shield 25 mm. in thickness, covered on both sides with india rubber.

The dosage depends on the intensity of the light, the quality of the tube, the distance of the tube, the frequency of the break intermission, and the length of the exposure. The dose should vary directly with the duration of the exposure.

The dosage may also be estimated by Holtznecht's chromoradiometer, the amount of radiation absorbed by its disc being estimated in Holtznecht's units. A small normal dose will produce a reaction of the first degree in five minutes, and an absorption of x rays of about three Holtznecht's units.

A normal dose will produce a slight reaction of the second degree in five to ten minutes and an absorption of three to five Holtznecht's units. A large normal dose produces a strong reaction of the second degree in ten minutes, intensity five Holtznecht's units. A double normal dose is followed by a reaction of the third degree, duration fifteen minutes, intensity eight Holtznecht's units. Certain diseases may be cured by a single exposure, producing an acute radiodermatitis of the

second degree. Dose, four Holtznecht's units, with seven minutes' exposure.

Some diseases require an acute inflammatory reaction every second month, others require a moderate exposure every week. Many diseases give better results if there is no inflammatory reaction. A degenerative action may be set up by a weak exposure once a fortnight. The healthy skin reaction is not the same for all portions of the body, and is influenced by age and sex. A diseased spot is more sensitive than normal skin. Idiosyncrasy is not a frequent cause of Röntgen burns.

The microscope appearances show that the Röntgen rays produce degeneration of the parenchymatous cells, and of the walls of the vessels, and acute or chronic degeneration with infiltration of the tissue, resulting in atrophy and scarring. There is also a stimulating effect on metabolism, as is seen in the cure of alopecia areata. There is also an arrest of itching and a suppression of pain.

The bactericidal power of x rays which has been recognized by experiments on cultures plays no part in Röntgen therapy, for the high intensity, twenty Holtznecht's units, which is necessary, is four times the normal dose.

The Association of American Anatomists.—The following was the programme of the meeting of the Association of American Anatomists held at Philadelphia last week:

Dr. Burt G. Wilder, A New Form of Brain Bequest; Dr. Burt G. Wilder, Some Current Terminological Inconsistencies That Are Apparently Needless; Dr. Edw. Anthony Spitzka, Report of a Study of the Brains of Six Eminent Scientists and Scholars Belonging to the American Anthropometric Society; Together with a Brief Description of the Skull of One of Them; Dr. R. B. Bean, On a Racial Peculiarity in the Brain of the Negro; Dr. J. S. Kingsley, The Mammalian Lower Jaw; Dr. Henry Fox, Notes on the Origin of the Carotid Gland and the Morphological Comparison of the Trigeminal and Facial Nerves in Mammalian Embryos (by invitation); Dr. William Keiller, Description of a Method of Making Wax Models for Teaching Purposes, with a Demonstration of the Anatomy of the Lymph Nodes of the Axilla as Illustrated by Such Models; Dr. William Keiller, Note on the Ligaments of the Mammary Gland; Dr. R. H. Whitehead, Results of a Study of the Development of the Oesophageal Epithelium; Mr. Charles F. Sylvester, Methods of Preparing the Salivary Glands for Study and Museum Purposes; Dr. Churchill Carmalt, Morphology of the Salivary Glands; Dr. C. M. Jackson, Topography of the Pancreas in the Human Fœtus; Dr. Lydia M. De Witt, Preliminary Report of Experimental Work and Observations on the Areas of Langerhans in Certain Mammals; Dr. J. L. Brenner, On the Anatomy of a 4.0 mm. Human Embryo from the Harvard Embryological Collection; Susanna Phelps Gage, The Total Folds of the Forebrain and Their Order of Appearance; Dr. John Warren, The Development of the Paraphysis and Pineal Regions in Necturus; Dr. Charles R. Bardeen, The Development of the Cutaneous Nerves in Man; Dr. Ewing Taylor, Normal Plates of the Development of the Rabbit; Dr. Arthur S. Vossburgh, The Inguinal and Femoral Fascia; Dr. Simon H. Gage, On Glycogen in Animal Tissues; Dr. George L. Streeter, On the Histogenesis of Spinal Ganglia in Mammals; Dr. Charles R. Bardeen (for Mr. A. O. Fisher), Marked Differences Between the Skin of Male and Female Frogs; Dr. William S. Miller, The Blood and Lymph Vessels of the Lung of Necturus; Dr. William S. Miller, The Mesentery in Amphibia and Reptilia; Dr. G. Carl Huber, On the Shape of the Uriniferous Tubules of Mammals; Dr. Ferdinand Schmitter, Cytological Changes in the Kidney Due to Different Strengths of Salt Solution; Dr. Charles S. Minot, Recent Additions to the Harvard Embryological Collection.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending December 30, 1904:

Smallpox—United States.			
Place.	Date.	Cases.	Deaths.
Florida—Jacksonville	Dec. 17-24	1	
Illinois—Chicago	Dec. 17-24	20	1
Illinois—Springfield	Dec. 18-24	5	
Kentucky—Louisville	Dec. 15-22	1	
Louisiana—New Orleans	Dec. 18-24	7	
Michigan—At 70 localities	Dec. 10-17	4	Imported
Minnesota—Meeker County	Dec. 12-19	1	Present.
Minnesota—Otter Tail County	Dec. 12-19	1	
Minnesota—Rice County	Dec. 12-19	12	
Minnesota—Wilkin County	Dec. 17-24	1	
New Jersey—Camden	Dec. 18-24	1	
New York—New York	Dec. 18-24	1	
Ohio—Cincinnati	Dec. 16-23	2	
Pennsylvania—Johnstown	Dec. 17-24	1	
Pennsylvania—Philadelphia	Dec. 17-24	1	
South Carolina—Charleston	Dec. 10-17	2	
Tennessee—Nashville	Dec. 17-24	4	
Washington—Pierce County (Tacoma included)	Nov. 1-30	2	
Washington—Walla Walla Co.	Nov. 1-30	5	
Washington—Seattle	Nov. 1-30	1	
Wisconsin—Milwaukee	Dec. 10-24	40	
Smallpox—Foreign.			
Argentina—Bahia Blanca	Nov. 18		Present.
Argentina—Buenos Ayres	Nov. 18		
Austria—Prague	Nov. 26-Dec. 3	18	22
Brazil—Bahia	Nov. 12-26	1	28
Brazil—Rio de Janeiro	Nov. 6-27	373	160
Ecuador—Guayaquil	Nov. 30-Dec. 7	1	3
France—Lyons	Nov. 26-Dec. 3	1	
France—Paris	Nov. 3-10	9	
Great Britain—Glasgow	Dec. 8-16	2	
Great Britain—London	Nov. 26-Dec. 10	3	
Gt. Britain—Newcastle-on-Tyne	Dec. 3-10	21	
Great Britain—Nottingham	Dec. 3-10	3	
Great Britain—South Shields	Dec. 3-10	2	
India—Bombay	Nov. 22-29	2	2
India—Calcutta	Nov. 19-26	2	2
Italy—Palermo	Nov. 26-Dec. 10	33	15
Russia—Odessa	Nov. 26-Dec. 3	1	
Turkey—Constantinople	Nov. 27-Dec. 4	1	15

Yellow Fever.			
Ecuador—Guayaquil	Nov. 23-Dec. 7	3	
	One case on S. S. <i>Limari</i> at Puna from Panama.		
Mexico—Coatzacoalcas	Dec. 10-17	2	
Mexico—Yucatlan	Dec. 11-17	1	
Panama—Panama	Dec. 12-19	3	

Cholera.			
India—Bombay	Dec. 22-29	1	
Russian Empire—Erivan	Nov. 22-28	914	363
Russian Empire—Jelssavetpol	Nov. 16-22		Present.
Russian Empire—Tachken	Nov. 27	18	8
Russian Empire—Tiflis	Nov. 16-22		Present.
Turkey in Asia	Nov. 28	72	43

Plague.			
Africa—Cape Colony	Nov. 6-19	5	
Arabia—Aden	Nov. 18-25	19	12
Argentina—Tucuman Province	Nov. 18	1	
Brazil—Bahia	Nov. 12-26	6	
Brazil—Rio de Janeiro	Nov. 6-27	101	35
Egypt—Tukh district	Nov. 19-26	2	2
India—Bombay	Nov. 22-29		74
India—Calcutta	Nov. 19-26		8
India—Karachi	Nov. 19-27	14	14
Paraguay—Asuncion	Oct. 6	20 cases weekly estimated.	
Peru—Guadalupe	Dec. 7		Present.
Peru—Lima	Nov. 1-15	6	

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending December 28, 1904:

BERRY, T. D., Assistant Surgeon. To proceed to Perth Amboy, N. J., and assume temporary charge of service during absence on leave of Passed Assistant Surgeon W. A. Korn. December 27, 1904.

KORN, W. A., Passed Assistant Surgeon. Granted leave of absence for seven days. December 27, 1904.

McCLINTIC, T. B., Passed Assistant Surgeon. Granted leave of absence for five days from December 27, 1904, under paragraph 191 of the regulations.

Births, Marriages, and Deaths

Born.

CHURCH.—In Fort Robinson, Nebraska, on Wednesday, December 21st, to Dr. James Robb Church, United States Army, and Mrs. Church, a daughter.

Married.

BARRINGER—DUNNING.—In New York, on Saturday, December 14th, Dr. Benjamin Stockwell Barringer and Dr. Emily Dunning.

HAVEN—HUMPHREY.—In Athol Centre, Massachusetts, on Wednesday, December 28th, Dr. Samuel Haven and Miss Helen M. Humphrey.

HAZELTINE—JOUBERT.—In Jamestown, N. Y., on Wednesday, December 21st, Dr. Laban Hazeltine and Miss Gertrude E. Joubert.

JOHNSTON—SMALL.—In Baltimore, Maryland, on Wednesday, December 21st, Dr. Richard Hall Johnston and Miss Mary Page Small.

LIST—WHITE.—In Stamping Ground, Kentucky, on Tuesday, December 20th, Dr. W. G. List and Miss Martha White.

PEPPER—GODFREY.—In Philadelphia, on Saturday, December 31st, Dr. William Pepper and Miss Mary Godfrey.

SHARP—OTIS.—In Kenton, Ohio, on Wednesday, December 21st, Dr. John R. Sharp and Miss Margaret E. Otis.

SHAWEN—BROWN.—In North Adams, Massachusetts, on Tuesday, December 20th, Dr. Charles Edwin Shawen and Miss Agnes Ora Brown.

Died.

BLAND.—In Baltimore, Maryland, on Sunday, December 25th, Dr. William F. Bland, in the seventy-eighth year of his age.

BOARMAN.—In Kansas City, Missouri, on Friday, December 16th, Dr. J. A. Boorman, Sr., in the eighty-fifth year of his age.

CAIRNCROSS.—In Wauwatosa, Wisconsin, on Wednesday, December 21st, Dr. J. W. Cairncross, in the fifty-fourth year of his age.

CLARK.—In Woodbury, New Jersey, on Monday, December 26th, Dr. Henry Clay Clark, in the seventy-fourth year of his age.

DOUCET.—In Philadelphia, on Thursday, December 22nd, Dr. Homer J. Doucet, in the eighty-fifth year of his age.

ECHENMENDIA.—In Havana, Cuba, on Monday, December 19th, Dr. M. D. Echenmendi.

GREENBANK.—In Ocean Grove, New Jersey, on Friday, December 30th, Dr. John B. Greenbank, in the seventy-sixth year of his age.

HAVEN.—In Coventry, Connecticut, on Monday, December 26th, Dr. William C. Haven, in the fifty-fourth year of his age.

HILL.—In Vincennes, Indiana, on Tuesday, December 27th, Dr. John Hill, in the sixty-third year of his age.

JURGENSOHN.—In Manawa, Wisconsin, on Monday, December 19th, Dr. B. G. Jurgensohn.

LILLISTON.—In Accomac, Virginia, on Tuesday, December 20th, Dr. A. Herbert Lilliston, in the thirtieth year of his age.

LOVETT.—In Carson City, Michigan, on Friday, December 16th, Dr. J. A. Lovett, in the fifty-first year of his age.

MALLORY.—In Hamilton, Ohio, on Wednesday, December 21st, Dr. Henry Mallory, in the eighty-third year of his age.

MCLEAN.—In Brooklyn, N. Y., on Friday, December 23rd, Dr. Henry C. McLean, in the fifty-fifth year of his age.

MCMONAGLE.—In Prescott, Ontario, on Tuesday, December 20th, Dr. Peter Reid McMonagle, in the seventy-second year of his age.

MILLAR.—In St. Louis, Missouri, on Monday, December 19th, Dr. William J. L. Millar, in the sixty-sixth year of his age.

NUTZEL.—In Comfort, Texas, on Friday, December 9th, Dr. O. L. Nutzel, in the twenty-fifth year of his age.

SMITH.—In Kansas City, Missouri, on Monday, December 19th, Dr. Thomas A. Smith, in the fifty-eighth year of his age.

TANTUM.—In Philadelphia, on Sunday, December 18th, Dr. James D. Tantum, in the forty-ninth year of his age.

WEST.—In Palestine, Texas, on Tuesday, December 27th, Dr. G. S. West, in the eighty-second year of his age.

ROSENAU, M. J., Passed Assistant Surgeon. Detailed to represent Service at Second Annual Mosquito Exterminating Convention, New York, N. Y., December 16 and 17, 1904. Detailed to represent Service at annual meeting of Society of American Bacteriologists at Philadelphia, Pa., December 27 and 28, 1904.

SALMON, T. W., Assistant Surgeon. To report at the Bureau, Washington, D. C., for special temporary duty. December 27, 1904.

SMITH, A. C., Surgeon. Detailed as inspector of unserviceable property at Camp Hutton, La. December 28, 1904.

VON EZDORF, R. H., Passed Assistant Surgeon. To report in person to Rear Admiral Walker, United States Navy, for duty in connection with quarantine in the Isthmian Canal Zone, Republic of Panama. December 27, 1904.

Board Convened.

Board convened to meet at the Hygienic Laboratory, Washington, D. C., on call of the chairman, for the examination and marking of applications for appointment as technical assistants in zoology, chemistry, and pharmacology. Detail for the board—Passed Assistant Surgeon M. J. ROSÉNAU, Director of Hygienic Laboratory, chairman; CHARLES WARDELL STILES, Chief of Division of Zoology; REID HUNT, Chief of Division of Pharmacology, recorder. December 22, 1904.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending December 31, 1904:

BUCK, CARROLL D., First Lieutenant and Assistant Surgeon. Granted ten days' leave of absence upon being relieved from duty with the First Battalion Philippine Scouts, World's Fair Grounds, St. Louis, Mo. Assignment to duty at Fort Des Moines, Iowa, changed to Fort Leavenworth, Kan.

HALL, JOHN D., Colonel and Assistant Surgeon General. Relieved from duty in the Division of the Philippines, and ordered to proceed to San Francisco, Cal., and report on arrival to the Military Secretary, for further orders.

JONES, PERCY L., First Lieutenant and Assistant Surgeon. Relieved from duty on the transport *Sumner* and ordered to report at the Medical Supply Depot, New York, N. Y., for temporary duty, to examine medical supplies now being delivered at that depot.

SHOOK, JAY R., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Leavenworth, Kan., and ordered to Fort Des Moines, Iowa.

SMART, ROBERT, First Lieutenant and Assistant Surgeon. Leave of absence extended fourteen days.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending December 31, 1904:

BELL, W. L., Passed Assistant Surgeon. When discharged from treatment at the Naval Hospital, New York, N. Y., ordered home and granted sick leave for three months.

GROVE, W. B., Surgeon. Detached from the *Atlanta* and ordered home to await orders.

GRUNWELL, A. G., Surgeon. Detached from the *Dixie* and ordered to the Naval Hospital, New York, N. Y., for treatment.

JANNEY, W. H., Acting Assistant Surgeon. Detached from the *Marcellus* and ordered to the *Cesar*.

KENNEDY, J. T., Passed Assistant Surgeon. Ordered to the Naval Station, Guantanamo, Cuba, and to additional duty on the *Amphitrite*.

LEDBETTER, R. E., Passed Assistant Surgeon. Detached from the *Lancaster* and ordered to the *Dixie*.

MEANS, V. C. B., Surgeon. Ordered to the Naval Hospital, Philadelphia, Pa.

PAGE, J. E., Passed Assistant Surgeon. Ordered to the *Lancaster*.

WHOLE NO. 1363.

Original Communications.

THE PRESENT STATUS OF RAILWAY EMERGENCY WORK.

By U. F. MARTIN, M. D.,

NEW YORK.

When a great deal of valuable material has been gathered concerning any subject, it would seem proper to limit introductory remarks simply to a statement of the purpose and scope of the article. An examination of the statistics of railroad accidents for the months of October, November, and December, 1903, as quoted in the *Railway Age*, for April 29, 1904, shows the following rather startling figures: Number of persons killed in train accidents, as shown in the reports made by railroad companies to the Interstate Commerce Commission. 446; number injured, 3,178; accidents of other kinds, including those sustained by employees at work and by passengers getting on or off cars, etc., bring the total number of casualties up to 14,485 (1,166 killed and 13,319 injured). The total number of collisions and derailments was 3,011 (1,832 collisions and 1,179 derailments), of which 287 collisions and 119 derailments affected passenger trains.

In our big cities every one is familiar with the methods pursued in taking care of injured people. The clanging of the ambulance bell shakes even the dullest out of his lethargy, and kindles interest in his mind for his fellows. Those who have travelled abroad remember the kindly ministrations of the ship's doctor. The ship's medicine chest is as old as the hills, and there is no division of opinion as to the proper solution of the medical problem in ocean carriers. Ships, as well as railroads, are built and manned primarily for the same object, the transportation of passengers and freight. When we turn to the contemplation of the medical problem of companies engaged in carrying people and freight on land, we find almost as many solutions as there are railroads, and in one large and growing branch, viz., the interborough trolley railroads, whose list of casualties

are in some respects greater than that of the steam railroads (see Table I), there has been, as far as could be learned, no systematic attempt to cope with the accident service.

TABLE I.

(*Railway Age*, January 22, 1904.)

Comparison of Casualties of Steam and Electric Railroads.

	Steam Road.	Electric Road.
Length of lines in miles.....	4,906	2,158
Passengers killed.....	7	16
Passengers injured.....	49	2,552
Number of employees.....	58,888	15,823
Employees killed.....	95	9
Employees injured.....	466	152
Others killed.....	161	59
Others injured.....	63	1,186
Total number killed.....	263	84
Total number injured.....	578	3,890

Without trying to present any ideal plan, an attempt is here made to compare the work being done on some of the leading railroads in this country, and, if possible, to gather together what seem to be the most practical lines of work as based upon the majority of opinions. The air is full of opposing convictions, full of contrary results, and this state of affairs may be traced, according to some well fitted to judge, to a certain lack of common sense in providing medical supplies, and to a visionary and theoretical attempt to utilize them. "Who is responsible," writes one surgeon, "for the wasteful follies in the medical service of railroads? Laymen own and operate the roads, and they alone are to blame for their own doings. If they employ theoretic lawyers, dreaming doctors, and blundering mechanics, they have none to censure but themselves. When a general manager expends \$7,000 for medical rubbish, when \$500 would equip his system with practical appliances, and does not know that he is dealing with a fine spun laboratory doctor, I do not blame the doctor, but the general manager."

This is the kind of medical chest which Dr. Howard Crutcher, of Chicago, declares is to be found on many railroads: "In the first place, it was of odd size, too large for a hand car and not large enough for a box car without some padding.

It was a veritable Pandora's box of compound pills and complicated powders, useless jars, antiquated mixtures, and grotesque absurdities. It cost, perhaps, more than a hundred dollars and was about as useful as an art gallery at the North Pole. How many thousands of dollars have been wasted in this sort of folly, it would be useless to conjecture; enough probably to relay many a mile of line with heavy steel and stone ballast."

In order to learn whether there was any systematic method employed, and commonly agreed upon by railroads, as being efficient in coping with the accident problem of medical service (for accidents form but one of the problems of the medical department), a series of questions was drafted and sent out to thirty-seven different railroads in all parts of the country. Answers of some nature were received from twenty-nine, three of which simply acknowledged the receipt of the letter. Eight failed to send any answer. The questions asked were as follows:

1. How many accidents occurred on your railroad lines last year, away from cities and medical aid?
2. How long in such instances did the injured have to wait for medical aid?
3. Do you consider it feasible to provide each passenger car and caboose with a small emergency box for first aid to the injured?
4. Have you any supplies at the present time on any of your trains for such emergency work?
5. Do you consider it practical to have trainmen receive a few lessons in first aid?
6. Have you a hospital car?
7. Would it be feasible to have a hospital car, at different points along the road, ready, like an ambulance in city work? Suppose it were a part of every wrecking train.

I did not expect much result from the first two questions and yet their importance is paramount, because, upon the question of delay in treating the injured, is based the whole subject of supplying trains with medicine chests, the need of instructions, etc. For, if the aid of physicians can be obtained within reasonable time, then question 5 is much simplified, if not done away with entirely. According to the statements of some surgeons question 3 can also be dismissed from consideration.

Considerable discussion gathers about the subject of supplying first aid packages, as reference to the tabulated answers, further on, will show. Here are two opinions, not quoted there. Dr. A. O. Williams remarks, "Now as to the emergency package on railroads, it has been tried and I doubt whether it has been adopted by many. In the last few years a great many roads have adopted the emergency package through the chief surgeon; but all have abandoned them. And why?"

Where do they put the emergency package in the ordinary caboose? No place in particular. It bumps around, and you can imagine the condition of it after bumping around for two, three, or six months. The great trouble is, railroad men do not know when accidents are going to happen. They come when they are least expected, and when they do happen, they may be a good way from the caboose, and when the caboose is found, the emergency package cannot be found, and is finally located on the floor where it has been kicked from one end of the caboose to the other, and is very little if any better than the handkerchief or road waste. And so, it has been found out, the emergency package is impracticable."

In contrast to this is the following quotation from an editorial in the February number of the *Railway Surgeon*: "We are not in accord with the enthusiastic advocates of first aid, who would arm the employees with hypodermic syringes, Esmarch tourniquets, and, we understand, even with the clinical thermometer. Nor do we believe, in common with some members of the profession, that instruction in first aid will do away with their means of livelihood, and hence discourage it. It seems to us that the true way lies midway between these extremes and that the matter is largely one of personal equation. It seems apparent also, that we must not expect the same degree of intelligence from the section hands that we do from train crews or skilled mechanics in the shops. The success of the movement on English railways is proverbial, and we should be loath to believe that the standard of intelligence in their employees is any higher than it is in the employees of roads in this country. Some one said that if the movement were beneficial, railroads would adopt it. Well, they are adopting it. The argument that it is suited only for roads traversing thinly settled parts of the country, loses much of its weight when we learn that it has been installed in the East, and, as before stated, in England, with the stations practically in sight of one another. As to the chest containing the supplies being knocked about and getting the contents filthy, this condition of affairs can be remedied as easily as can the use of impure ice and drinking water."

An examination of the answers received shows six railroads which do not consider the question practical, or having provided a first aid package once, subsequently discarded it; sixteen which considered it practical, four of these still having the matter under consideration, and one, the Boston and Albany Railroad, which seemed to find some objection to the system; four gave no answer to the question.

TABLE II.
Answers to Question 3.
Practical.

Bangor and Aroostook.
Boston and Albany.
New York, New Haven, and Hartford.
Pennsylvania.
Lehigh Valley.
Lake Shore and Michigan Southern.
New York Central and St. Louis.
Colorado Midland.
Rock Island.
Chicago and Alton.
Seaboard Air Line.
Atlantic Coast Line.
Chesapeake and Ohio.
Père Marquette.
St. Louis and San Francisco.
Grand Trunk.

Not Practical.

Boston and Maine.
Wabash.
Chicago and Great Western.
Chicago and North Western.
Missouri Pacific.
Missouri, Kansas, and Texas.

No Answer.

Chicago, Milwaukee, and St. Paul.
Chicago, Burlington, and Quincy.
Union Pacific.
Northern Pacific.

As a supplement to the above table, the following answers were printed in the February number of the *Railway Surgeon* to a letter sent by Mr. E. Hadra, of Dallas, Texas, to the railroad officials of that State. It has the value of being direct testimony. A part of Mr. Hadra's letter is here printed:

"In view of the many railroad accidents that have occurred in our State of late, some attended with loss of life, and nearly all with personal injuries more or less severe, it has occurred to me that it would be a good idea, and a great step in the direction of alleviating human suffering, if the various railway companies of the State would place in some convenient place in the train, say the baggage car, an emergency case of simple surgical appliances, such as bandages, cotton, adhesive plaster, liniments, antiseptics, etc., they being intended only to tide over the time between the accident and the arrival of surgical aid, and to prevent blood poisoning. This would cost but little. The railroads already have such things in their hospitals. They also have their carpenter shops and can easily make small wall cases or chests for same, and at very little cost, or get something very similar to the present army emergency package. This would suggest itself as about right."

Avery Turner, vice-president and general manager of the Pecos Valley lines, replied: "I quite

agree with you that it would be an excellent idea to carry an emergency case, or what is known in army circles as a first aid, in case of injury, in our baggage cars, shops, round houses, etc. I thank you for calling the matter to my attention."

D. B. Keeler, vice-president and traffic manager of the Fort Worth and Denver City Railroad, answered: "The idea you suggest is a very good one, and we may see fit later on to put it into effect."

W. T. Elbridge, vice-president and general manager of the Cane Belt Railway, said: "I consider your suggestion a good one and have referred your communication to our chief surgeon with a recommendation that we have our baggage cars equipped with a case of emergency supplies."

The reply of E. E. Shackford, vice-president and general manager of the San Antonio and Gulf Railroad, was: "In reply, I beg to say there is no doubt your idea is correct, and I believe the matter has for some time been under consideration by the larger lines, not only as it pertains to passenger and freight trains, but also to those in the work gangs where an extra number of men are engaged in repairs and construction, especially to those located at remote or isolated points."

C. H. Markham, vice-president of the Houston and Texas Central, answered: "In reply, I beg to say that this is a matter which our chief surgeon has had under consideration for some little time, and it is our intention to make such provision as may be necessary to give our patrons the benefit of every possible attention. Should we be so unfortunate as to have any wrecks on our lines. You may also consider this letter as applying to the Houston, East and West Texas, and other so called Southern Pacific lines in Texas."

The *Railway Journal* has this to say of the effort to get first aid boxes on all freight and passenger trains in Texas: "This is a commendable move, and one that should be followed by every line in the country, irrespective of locality; these emergency boxes are to be equipped with such instruments and medicines as the chief surgeon of the road considers important. When this system has been adopted, the chief surgeon of the line gives lectures to trainmen at their terminal points, educating them in a brief way as to what to do, and how to handle dressings, etc., in case of emergency. Brief directions are also pasted in the boxes for ready reference."

So much for a statement of opinion. What has been done, and what is being done, is more to the point. The Pennsylvania Railroad has arranged to equip all baggage, mail, express, shops, and wrecking cars, terminals, yard office, shops, and important stations with first aid boxes. and in-

EMERGENCY PACKAGE

CONTENTS

One ounce Absorbent Cotton,
One ounce Antiseptic Powder
in wood box,
Three Safety Pins,
One 24 inch Roller Bandage,
One 1 inch Gauze Bandage.

Contained in tin box wrapped and hermetically sealed with full and complete instructions for use.

CAUTION.

Whenever this package is opened for any purpose it must be turned in at once, with its remaining contents, for inspection and refilling.
HOWARD CRUTCHER, M. D.
Consulting Surgeon.

THE CHICAGO & ALTON
RAILWAY COMPANY'S
**EMERGENCY
PACKAGE**
DIRECTIONS INSIDE

[FACSIMILE OF WRAPPER]

NOTICE.

This package is the property of THE CHICAGO & ALTON RAILWAY COMPANY, and its use by unauthorized persons is prohibited. Whenever a package is used the person who opens it must leave inside the box a slip of paper, giving his name, the date, the place where used, the name of the person for whose relief it was opened.
J. H. BARNETT,
Gen'l Superintendent.

(END LABEL)

FIG. 1.—The Chicago & Alton Railway Company's emergency package.

struction of employees in first aid will also be carried on. A stretcher is provided which, when not in use, may be taken apart; making a bundle, 3 feet, 6 inches, by 6 inches in diameter, ready for use either as a stretcher or as a cot. The first aid boxes consist of an outside wooden box with hinged lid, 8½ inches by 6 inches by 4 inches, permanently secured in locomotives and at other points where installed. Each wooden box contains a sealed tin box provided with six sterilized first aid packages. Each packet contains one large triangular bandage, one ordinary roller bandage, two compresses, two safety pins, but no drugs or liquors. When the seal of the tin box is broken, a new one is put in place and the one with a broken seal sent in and refilled. For convenience of inspection, the wooden boxes have a seal on the lid fastener.

A smaller package than this is employed by the Chicago and Alton Railroad, measuring 6 inches by 3 inches by 2 inches. A reproduction of the same is here shown, together with the label on the outside:

The leaflet which accompanies this small box, is admirable for its terseness and clearness, and is published as a type of sensible advice. On the

last page is an illustration, showing how to apply the Spanish windlass to stop bleeding:

THE CHICAGO & ALTON RAILWAY
COMPANY.

EMERGENCY PACKAGE.

DIRECTIONS FOR USE.

This package contains dressing powder for wounds, a narrow gauze bandage, absorbent cotton, a strong muslin bandage, and safety pins.

In ALL injuries where the skin is seriously broken, pour on the wound powder VERY FREELY, apply a pad made from the gauze bandage, and hold in place with the muslin bandage properly secured with safety pins. Where additional padding seems necessary, use the cotton, AFTER the gauze bandage has been applied next to the wound. Do NOT TOUCH THE WOUND WITH THE FINGERS or handle it beyond applying the dressings.

BLEEDING: If about the head or body, pour on wound powder freely, apply a snug pad of gauze, then cotton, and hold pad tightly in place with hands or bandage until the surgeon can be called.

For bleeding of an arm or leg, take a piece of the big bandage, about two feet long, tie the ends together, pass the loop thus made over the limb to a point slightly above the wound, pad it with the cotton, so that it will not cut into the flesh, and tighten with a stick or lead pencil by twisting, until the bleeding stops. (See cut on last page). KEEP THE WOUNDED LIMB HIGHER THAN THE HEAD. In ALL cases of

bleeding or injury, keep the patient QUIET and WARM, and the HEAD LOW.

STIMULANTS: By far the best stimulant is STRONG HOT COFFEE, without seasoning. It may be given ABUNDANTLY. When coffee cannot be had, plain HOT water is the best substitute, and may be given without limit.

CAUTION: Whenever this package is opened for any purpose, it must, IN ALL CASES, be turned in immediately for inspection and refilling. An unsealed package must not be used under any circumstances.

HOWARD CRUTCHER, M. D.,
CONSULTING SURGEON.

The firm supplying these has quoted the following prices: thirty cents apiece for emergency package in lots of one hundred or more; fifteen dollars for passenger chest for use of surgeon; three dollars for Chicago and Alton stretcher.

FIG. 2.—The Chicago & Alton stretcher.

Dr. D. C. Brockman, of Ottumwa, Ia., is of the opinion that most of the boxes supplied to railroads are absolutely worthless, and suggests the following, which the factories in his town have accepted, as well as the railroad with which he is connected. The pads are prepared as follows: Four thicknesses of gauze, 8 inches by 10 inches, are laid on a pad

FIG. 3.—The same, folded to carry.

of cotton a little larger, say, 10 inches by 12 inches; over the face of the gauze is spread 2 to 3 drachms of some non-toxic antiseptic powder. The pad is now folded together so as to hold the powder in the centre, wrapped in waxed paper, and closed in envelopes or cartons,

then packed in a suitable box. This is the smaller sized pad and is sufficient for an injured hand or foot, or small lacerated wounds on the extremities. A larger package is made in the same way, only three or four inches larger each way, to be used in compound fractures or dislocations, or in extensive injuries to head or trunk. One or two dozen of each size pads are packed together in a suitable box, with a dozen each of two, three, or four inch bandages, and three one yard rolls of picric acid gauze. On the lid of the box should be a cut of a Spanish windlass and very brief directions for its application to stop hæmorrhage; also directions like this on each package: "Cut the clothing from the wound, open package of dressing, and spread powdered surface over wound and apply bandage, to hold it in place."

On the picric acid gauze jars, should be printed: "For burns. Wrap the burned surface with the picric acid gauze, and apply bandage over it. Do not touch burn with anything else." Three dozen pads, bandages, and picric acid gauze, all in a neat box, can be retailed at about \$7.50.

Over the Chicago and Eastern Illinois Railroad and the Frisco System, the emergency case contains one tourniquet, $\frac{1}{2}$ inch by 3 inches; four ounces of antiseptic absorbent cotton in a sealed box; four packages of roller bandages; sterilized gauze, bichloride gauze, boric acid gauze, and three ounces of whiskey in a small flask. At the larger stations along the line, there are surgeons at hand, and a small case is provided, including a tourniquet; three boxes of absorbent cotton, one quarter of a pound in each; two packages each of sterilized, bichloride, and boric acid gauze; silk and catgut ligatures in glass tubes; forceps, needles, scalpel, and scissors; ether, morphine, and, perhaps, whiskey.

(To be concluded.)

Philadelphia Physician Fined.—Dr. Charles M. Burk, who was arraigned before Magistrate Kochersperger for failure to report the case of William McGinty as one of smallpox, was fined five dollars and costs on January 4th. Dr. Burk was adjudged to have committed a technical, although not an intentional, violation of the law.

A CLINICAL STUDY OF MYOIDEMA WITH ESPECIAL REFERENCE TO ITS OCCURRENCE IN PULMON- ARY TUBERCULOSIS.*

By HENRY L. SHIVELY, M. D.,

NEW YORK.

VISITING PHYSICIAN TO ST. JOSEPH'S HOSPITAL, PHYSICIAN
TO THE PRESBYTERIAN HOSPITAL DISPENSARY, DEPART-
MENT OF HEART AND LUNGS.

A peculiar muscular contraction, very usually present in cases of tuberculosis of the lungs may be elicited by sharp percussion with the forefinger. The contraction occurs in the group of fibres near the point of impact, and appears as a well defined, hard ridge, tetanic in character, and raised in a direction at right angles to the course of the muscle fibres. This whipcord like elevation continues for a few seconds and then subsides. Sometimes a wave or ripple starting from the primary contraction may be seen rolling under the skin and gradually fading away on either side respectively, toward the origin and insertion of the muscle. Jeanselme and Lermoyez (1) where this wave is seen, have, in the majority of their cases, found it to be propagated only toward the insertion of the muscle. Where I have observed it there have usually been two distinct secondary waves transmitted in opposite directions. Occasionally there may be seen upon the crest of the ridge a tremulous, oscillating movement which disappears before the subsidence of the original elevation. When the nodule or ridge is of slight extent it can sometimes be best detected by running the finger lightly over the surface of the muscle, and thus feeling the elevated fibres. Some observers have remarked an initial pallor following the percussion blow of the finger, succeeded soon by a bright, red spot which persists for some time and resembles the *tache cérébrale* of meningitis. This appearance is inconstant and does not constitute any essential part of myoidema, but is rather to be considered a vasomotor reflex, affecting the small cutaneous vessels, causing first a slight contraction of their calibre and afterward a temporary paralysis of the local vasoconstrictors. Myoidema itself is a purely muscular phenomenon. It was described and named by Lawson Tait (2) in 1872, but was observed as long ago as 1830 by Dr. William Stokes (3) of Dublin. Cornet (4) mistakenly credits Maurice Schiff with priority in the discovery of myoidema. Schiff (5) described it under the name of idiomuscular action (*idiomuskuläre Bewegung*) in 1851 and made an elaborate physiological investigation of its occurrence in the

lower animals. He was preceded, however, not only by Stokes, who casually directed attention to it in 1830, but also by a New York physician, Bennett Dowler (6), who published a full and accurate description of the phenomenon as he observed it on the cadaver in 1846.

Dowler's experiments were limited apparently to the dead body, and this early observer deserves more recognition than he has received for the originality of his observations, many of which have been repeated independently and were published in 1885 by Jeanselme and Lermoyez. In Dowler's monograph myoidema is thus described: "Blows with the knuckles over the pectoral muscles caused them to heave up into knotty masses. Sometimes post mortem rigidity sets in during the paroxysm of contraction, producing a very singular phenomenon, a hard mass, which, continuing for hours, feels like bone. I have known this to be mistaken for a fracture badly set, or for a bony tumor." Again: "A third blow caused the biceps to be convulsed; it gathered up in a knotty heap, which, by forcible extensions and frictions, was at length removed temporarily, but in half an hour it returned and was unchanged as long as observed, being to the touch like a bony tumor."

Frequently associated with this nodular form, or true myoidema in its etymological sense of a swelling of the muscle (*μύων* and *οἰδήμα*), is a longitudinal furrow also elicited by tapping which, however, follows the direction of the muscular fibres and appears as a linear depression or sulcus of considerable length, often extending from the origin to the insertion of the muscle. To this appearance has been applied the name fascicular or fibrillary myoidema to distinguish it from the nodular variety, although it is evident that the word myoidema is somewhat of a misnomer, except when used in connection with the latter form. Fascicular myoidema is not to be confused with the quivering movements of muscle fibres or fibrillary contractions which are a feature of progressive muscular atrophy and other lesions of the central nervous system. Fibrillary contractions, occurring in degenerative lesions of the cord and brain, are usually clonic in character; in myoidema of both varieties, on the contrary, the appearance is invariably sustained and does not intermit while it lasts. Fascicular myoidema is always of much shorter duration than the nodular form, which, in the algid stage of cholera, has been observed by Jeanselme and Lermoyez (1) to be prolonged for more than half a minute. Usually, however, the duration on the living body of the nodular variety does not ex-

* Read before the West End Medical Society, February 27, 1904.

FIG. 1.—Nodular myoidema.

ceed from five to ten seconds. Nodular myoidema was first observed by Stokes in the pectoralis major. It is also usually well marked in the deltoid, latissimus dorsi, supraspinatus, infraspinatus, and biceps. In the cases which I have observed the nodular has been most perfectly seen in the biceps (Fig. 1) and the fascicular in the pectoralis major (Fig. 2). Either form of myoidema may occur alone or, as is more usually the case, both are associated in the same subject. Generally in cases where the nodular is present the fascicular may also be elicited. The latter, however, more frequently than the nodular occurs alone. In tuberculosis of the lungs the nodular variety is more marked in the moderately advanced and advanced cases. The fascicular form is very generally present even in the earliest cases, and usually persists through every stage of the disease.

The muscles in which myoidema may be obtained have not been found to exhibit any characteristic or constant variations in their electrical irritability. With both galvanic and faradaic currents, some cases show increased excitability, others diminished, and some only the response of the normal muscle. In no case has the reaction of degeneration been obtained.¹ The typi-

cal phenomenon of myoidema may usually be elicited ten or twelve times in quick succession. The muscular irritability then appears to be exhausted and the response is feeble or fails entirely. Sometimes a fresh group of fibres adjacent to the exhausted area will respond, although the stimulus is continued at the same point. In any case the exhausted fibres quickly recuperate and the phenomenon reappears in as marked a degree as at first. In a few instances I have been able to obtain myoidema of both kinds as many as twenty-five or thirty times before exhausting the muscle. The fascicular has been less carefully studied than the nodular variety, and has usually been described as analogous to it. My observations, however, have led me to the conclusion that fascicular myoidema is not a contraction at all, but is on the contrary actually a relaxation of a bundle of muscular fibres, due to a temporary loss of the normal muscular tonus caused by the impact of the percussion blow. This relaxation consists in a momentary collapse of the flaccid fibres affected, and there is thus produced a linear sulcus in striking contrast to the rigid, salient elevation of the nodular variety. In the healthy subject mechanical stimuli are usually uniformly transmitted to the entire muscle which responds with a contraction of the muscle as a whole; in the nodular form of myoidema there is a limited contraction of the fibres adjacent to the point where the stimulus is applied; in fascicular myoidema there is no contraction, the stimulus producing instead a relaxed state of the fibres at the point of impact greater than that normally present when the muscle is at rest.

No mention of the fascicular variety is made

FIG. 2.—Fascicular myoidema.

¹ I am indebted to Dr. M. G. Schlapp, of the Department of Nervous Diseases in the Presbyterian Hospital Dispensary, for assistance in making the electrical examinations in a number of these cases.

by Corriet in his admirable treatise on tuberculosis.

I have rarely been able to elicit either variety in the muscles of the lower trunk, or thigh, or leg in cases of tuberculosis of the lungs, and a careful search of the literature of the subject has disclosed no mention or attempted explanation of this very singular limitation of the phenomenon to the muscles of the chest and upper extremity. Rudolf Schmidt (7) invokes the anatomical relationship of the apex of the lung with the brachial plexus as a cause of the cutaneous paresthesias of the hand and arm, and the supraclavicular tenderness on deep pressure which he has observed in subjects of pulmonary tuberculosis. Luschka (8) in his *Anatomy* makes this relationship plainer than does either Gray or Quain.²

It has appeared that in this intimate anatomical relation of the cords of the brachial plexus to the lung apex may be found also a possible explanation of the occurrence of myoidema in cases of tuberculosis of the lungs with rare exceptions only in the muscles supplied by branches of the brachial plexus. The apices of the lungs are almost invariably first affected by tubercle, and even slight pathological changes in this situation could readily affect the adjacent nerve trunks, either mechanically, through injurious pressure effects, or possibly also by the absorption of toxins, the products of the vital processes of the tubercle bacillus. Dowler's early researches and the later investigations of Jeanselme and Lermoyez show that myoidema can always be obtained after death. It is probable that in the healthy, living state an inhibitory influence is usually exerted through the nerve supply of the muscle, and this would account for the rarity of the phenomenon during life except in diseased conditions. In pulmonary tuberculosis this inhibitory function of the nerve is restrained or interfered with by mechanical pressure or toxic irritation due to tuberculous infiltration of the contiguous lung apex, and we thus have myoidema present in the muscles of the chest and upper extremity and usually only in these situations.

In other conditions myoidema is found in other situations. Jeanselme and Lermoyez report its occurrence in the adductors and quadriceps of the thigh and in the muscles of the calf in cases of

Asiatic cholera, and in typhoid fever and lobar pneumonia I have found it as well developed in the muscles of the trunk and lower extremity as in the chest and shoulder muscles. Jeanselme and Lermoyez direct attention to the unique concurrence of favorable conditions met with in cholera for the production of myoidema. The flaccid, inelastic skin, made tense by loss of interstitial fluids and closely adapted to the underlying muscle, which through loss of subcutaneous fat is thus almost directly exposed to the blow of the percussing finger, the great susceptibility of the voluntary muscles to cramps in cholera, the profound prostration, subnormal temperature, and loss of body fluids are all conducive to the phenomenon, and it is in cholera that it is seen in its most exaggerated form except upon the cadaver. Some extreme cases are reported wherein the nodular variety attained the volume of a good sized nut and could only be made to disappear by vigorously kneading and rubbing the affected muscle. Post mortem myoidema may persist for many hours.

It is somewhat extraordinary that the clinical significance and real nature of a phenomenon which has been known so long should be so little understood. The most contradictory views are expressed regarding it. Tait in his monograph declared that myoidema was one of the most certain signs of phthisis; that it was an absolutely certain indication of softening deposits, so that in exact proportion to its intensity was the amount or rapidity of lung destruction and the consequent gravity of the case; that increase of softening, increase of muscular irritability, and loss of weight always went together; and that he had been able by this symptom to diagnosticate between typhoid fever or acute bronchitis on the one hand and softening tubercle on the other. Sir William Broadbent, quoted by Walsham (9), regarded the sign of great value in early phthisis, placing it with the apical rale as of first importance. J. W. Moore (10) states that "myotatic irritability of the pectoral muscles and of the platysma myoides (myoidema) is a valuable sign." It is unusual to have well developed myoidema in the platysma and Moore is the only observer who has especially noted it in this situation. Vincent D. Harris (11), of the City of London Hospital for Diseases of the Chest, considers myoidema a sign of pathological import, but attaches to it little diagnostic value. Hugh Walsham (9) says "I have never been able to obtain this sign in a perfectly healthy person," but declares he "never found it in an early case." Also, "I think that myoidema is nearly valueless as an early sign of pulmonary tuberculosis. It

² "Durch Vermittlung der Pleura parietalis steht jenes von einer directen knorpelig-knöchernen Einhüllung freie Segment der Lunge mit mancherlei Gebilden in naher räumlicher Beziehung. Auf ihm ruht mit seiner Concavität ein Stück der Arteria subclavia, der Anfang der Arteria vertebralis und Mammaria Interna, sowie der Plexus brachialis." Again: "Es ist auch sehr wohl denkbar, dass mit Erschlaffung der Rippenhalter die Lungenspitze zwischen Scalenus internus und medius vorgedrückt wird, wobei sie die Arteria subclavia und den Plexus brachialis auseinanderwirft." Luschka, quoted by Schmidt.

only becomes well marked when other physical signs leave no doubt about the diagnosis of pulmonary tubercle." Jeanselme and Lermoyez (1) and Labbé (12) go so far as to deny that myoidema is in any sense pathological, declaring it to be a physiological appearance which can always be detected in health, and which is merely increased in disease. The truth amid these conflicting statements will probably be found to lie in a middle opinion. Samuel West (13) in 1879 pointed out that the contention of Tait was untenable in that the sign was by no means limited to phthisis, but could be obtained in other exhausting diseases, being almost constantly present in enteric fever. In a series of 275 general medical and surgical cases he found myoidema present in one out of every three, and that it was twice as common in the medical as in the surgical wards, one out of every two in the former, one out of every four in the latter. The surgical conditions in which he detected it included simple and compound fractures, diseases of the hip and spine, necrosis, and amputations. The medical cases included besides phthisis, hemiplegia, paraplegia, cerebral abscess, locomotor ataxia, muscular atrophy, valvular heart disease, cirrhosis of the liver, nephritis, diabetes, jaundice, rheumatic fever, pleurisy, pneumonia, pneumothorax, and empyema. He observed that it is usually absent in children. This does not agree with my own experience, as I have generally found it present and well marked in children, in conditions in which I would expect it in adults. Jeanselme and Lermoyez have detected well defined myoidema in persons abstaining from food or on a milk diet, and in four cases of "disease of the stomach" (nature of disease not specified). In a number of instances I have seen it in acute and chronic bronchitis, in three cases of carcinoma of the breast, in aneurysm of the arch of the aorta, and in secondary syphilis in addition to the diseases enumerated by West, and I have also observed it in the perfectly healthy individual, contrary to the experience of Walsham. It is unusual, however, to find the sign in an appreciable degree in health. In the negro race myoidema appears to be more exaggerated than among whites.

In a series of 750 consecutive cases of tuberculosis of the lungs myoidema was found to be present in 703. Of these 750 cases, 630 were under observation at the Presbyterian Hospital Dispensary, 63 at St. Joseph's Hospital, and 57 were seen in private practice. Of the entire number 196 could be classed as incipient, 475 as moderately advanced, and 79 as advanced cases. Of the 196 incipient cases both varieties of myoidema could be obtained in 135, the nodular alone in 19,

the fibrillary alone in 24, and neither form in 18 cases. Of the 475 moderately advanced cases both kinds were present in 379, the nodular alone in 30, the fibrillary alone in 37, and neither form in 29 cases. Of the 79 advanced cases both varieties were to be obtained in 74, the nodular alone was found four times, the fibrillary alone was elicited in one case, and in no case was the sign not present at all. In this classification the cases have been considered incipient in which physical signs are limited to one apex and the patient's general condition is good; moderately advanced those wherein there is some involvement of both lungs with considerable loss of flesh and strength; and advanced those generally recognized as incurable with extensive lesions in both lungs. In a number of instances where myoidema was present and in which physical signs were wanting or doubtful, the patient has been kept under observation and later unmistakable signs of pulmonary tuberculosis have developed, or bacilli have appeared in the sputum. In other cases of incipient or moderately advanced tuberculosis in which there has been marked improvement in nutrition under treatment, it has been noted that as the patient gained in weight and strength myoidema became less marked or might even completely disappear.

It would seem that a phenomenon found in such widely different conditions, and which is not even constant in tuberculosis of the lungs could have but little diagnostic significance, and yet it cannot be dismissed as being entirely without value. From the 750 cases here reported it will be apparent that it is present in the great majority of all cases of tuberculosis of the lungs observed, it is usually obtained even in the incipient stages of the disease, and it is thus not without some importance as an addition to the syndrome of signs and symptoms which makes the early diagnosis less difficult. It is such a striking and conspicuous objective sign that it can never be overlooked when properly sought for, and should make the person presenting it a subject of suspicion until tuberculosis can be definitely excluded. When it is remembered that the earliest diagnosis of beginning pulmonary tuberculosis is only made possible by the careful observation and skilful weighing of little signs and slight deviations from the normal, it would appear that myoidema, which in itself is not in any sense pathognomonic, is yet one of the indications of departure from health which should receive some consideration.

RADIUM; A REVIEW OF THE LITERATURE.

By FRED G. HODGSON, M. D.,

ATLANTA, GA.

The action of the x rays in rendering bodies transparent was first described by Röntgen in 1895. This was followed by the discovery of certain rays given off from the metal uranium, by Becquerel in 1896. This discovery was much talked of by scientific investigators, and Mme. Curie in Paris became especially interested and began her investigations. She found that pitchblende, composed mainly of thorium and uranium, gave off rays similar to those described by Becquerel. She separated the uranium and found that the *remaining mass* was more radioactive than the uranium. Then with the aid of her husband, Professor Curie, she continued to analyze the remaining mass by a very complicated and tedious method, each time selecting the portion that was most radioactive, until they finally obtained a substance in the form of a "chloride," to which they gave the name *Radium*. The element radium itself has not been isolated. Mme. Curie, however, determined its atomic weight to be 225, thus showing it to be one of the heaviest metals known and putting it in the group with magnesium, calcium, strontium, and barium according to the periodic law. Mme. Curie took two tons of pitchblende, and after several months of repeated precipitation, filtration, crystallization, and decantation, obtained $\frac{1}{10}$ grain of radium; just $\frac{1}{10}$ grain from 4,000 pounds!

Occurrence.—Radium occurs chiefly in the pitchblende found in Bohemia, which is used in the manufacture of Bohemian glass. The Austrian government has now forbidden the exportation of this pitchblende for fear of its interference with the glass manufacture. This accounts for the very high price of radium. A specimen which originally cost \$80.00 is now sold for \$300.00. Some medicinal springs and baths are reported to contain radium salts or radioactive substances, but these reports have not been very well substantiated. If it is present it must be in very minute quantities. Careful search is now being made in various parts of the United States for radium-bearing substances.

Physical and Chemical Properties.—The bromide of radium is the salt generally used. It occurs in small white crystals, is soluble in water. Its chemical properties are very similar to those of the barium salts. It gives a carmine color to a Bunsen flame. It has a characteristic spectrum. Radium chloride gives off heat continuously for several years without any appreciable diminution; 10.8 grains would cause a thermometer to rise 3° C. Radium salts in solution will after a short time give out the same quantity of heat as the dry salt. The most interesting property of radium is the spontaneous giving off of rays. These are known respectively as the α , β , and γ rays:

α rays are *very minute particles of matter* about twice the weight of a hydrogen atom and traveling at the rate of 20,000,000 metres a second. They are only very slightly penetrating, being stopped by glass or thin mica plates. The particles are positively charged electrically as determined by an electroscope. These rays can be deflected by a magnet toward the negative pole.

β rays are *still more minute particles of matter*, being only $\frac{1}{1000}$ the weight of a hydrogen atom. They travel 200,000,000 metres a second, about the same velocity that light has. The particles are negatively charged with electricity, and are deflected by a magnet, but in the opposite direction from and more strongly than the x rays. They are probably the most valuable rays therapeutically. They are moderately penetrating, being said to penetrate the skin for about one half inch. They are considered by some to be identical with the cathode rays of a Crookes's tube, and are converted into x rays when deflected by a solid body (Pusey). McKenzie attributes burning of the skin to these rays.

γ rays are *not particles of matter at all*, but are undulations of ether. They travel with enormous velocity. They resemble very closely the x rays from a "hard" or high vacuum tube, in that they are *very penetrating*. They will pass through 5 cm. of cast iron: they lose only one half their value in

passing through 8 cm. of aluminum. Bones offer practically no resistance to these rays.

They do not discharge an electroscope, and are not deflected by a magnet.

99 per cent. of radiant energy is found in the α rays.
0.9 per cent. of radiant energy is found in the β rays.
0.1 per cent. of radiant energy is found in the γ rays.

The α rays, which are in the largest quantity, have practically no actinic or chemical properties. The α rays are in such minute quantity that it is thought that the β rays produce the bulk of the effect upon living tissues.

When we consider what minute quantities of radium are used in experimentation, usually a fraction of a grain mixed with some inert material like white sand, it is easy to let the imagination play. It has been suggested that with a pound the house could be heated and cooking done for a large family for generations; or with a sufficient quantity a transatlantic steamer could be driven back and forth across the ocean indefinitely.

The combined effects of these radiations are:

1. *Fluorescence and Luminosity.*—This is beautifully illustrated in the little instrument invented by Crookes and known as the Spinharscope. This consists of a cylindrical brass tube about one and one half inches in diameter, by three inches long. At one end is a circular fluorescent screen of calcium fluoride, and in front of this is a little movable arrow. On the under surface of the tip of the arrow, that is just opposite the screen, is a minute particle of radium. At the opposite end of the tube is an adjustable lens. Upon going into a dark room and adjusting the lens to one's eye, one can see minute particles of light flying off from the screen in every direction, and dancing around at a rapid rate, suggesting a shower of shooting stars. It makes a beautiful little demonstration. Slight phosphorescence is also produced by radium, but it is not nearly so marked as with the Finsen rays.

2. *Coloration of Bodies.*—Diamonds, glass, quartz, and similar substances are variously colored in the presence of radium rays. Jewelers sometimes take advantage of this in giving deeper coloring to slightly "off-color" diamonds.

3. *Chemical and Photographic Effects.*—Paper becomes brittle after prolonged exposure. Ozone is formed in the air about radium. Rays are not affected by extreme heat or cold. A photographic plate is affected when covered with black paper. Images of various objects can be reproduced, as with the x rays. A photograph of a mouse shows the outline, but the bones do not show.

4. *Physiological and Pathological Effects.*—Seeds exposed to radium for a short time are stunted in

growth; after longer exposures they fail to germinate. Small mice and young guinea pigs are killed by a few hours' exposure. Living skin is burned, and hair will fall out just as after exposure to x rays. Many pathological growths and skin lesions can be affected by radium rays; this will be discussed later.

Besides giving off heat and three different kinds of rays, radium possesses another remarkable property. It gives off a *gaseous emanation*. This can be collected by putting some radium in the lower bulb of an hour glass shaped tube, and after several hours sealing the connection between the two bulbs and separating them. The upper bulb will contain the emanations. This gas is found to be temporarily radioactive and causes phosphorescence. It acts like other gases and can be condensed in liquid air. After the lapse of several weeks a most wonderful and unheard of transformation occurs. It has been shown by the noted chemist, Ramsay, that this gas is spontaneously transmuted into the element helium, and gives the characteristic spectrum of that element. If the above conclusion proves true this is the only instance known to man where one element is converted into another. This makes the hope of the old alchemists seem a real possibility.

The intensity of radioactivity of a specimen of radium is based upon the activity of an equal mass of uranium used as a unit. Specimens vary in strength from 240 to 1,000,000 units. This activity can be determined by several methods:

1. The rapidity with which it discharges a gold leaf electroscope due to the ionization of the surrounding air.

2. The effect upon a photographic plate enclosed in dark paper.

3. The way it illuminates a piece of willemite or sulphide of zinc.

Luminosity in the dark is *not* a test of radioactivity.

Certain bodies under the influence of radium become temporarily radioactive. There seems to be some difference of opinion as to whether solutions in which a tube of radium has been left become radioactive. Many claim wonderful healing properties and certain cancer cures for these so called radioactive solutions, but these views have not been substantiated. A radium salt in solution does after a time become radioactive, but the mere placing of a sealed tube of radium in a solution probably does not render it very active.

The source of the continued energy of radium, which does not seem to diminish in the slightest, is unknown. Some say it is due to the movement of its atoms or electric currents around the atoms. Others say it absorbs energy from the surrounding

medium. Some conjecture that the sun must contain radium in large quantities to account at least in part for its heat and energy.

ACTION OF RADIUM UPON LIVING TISSUES.

Gross Effects.—Take, for example, some Curie radium of 300,000 activity and place it upon the healthy skin on one spot for one hour, on another spot for two hours, and on a third for five hours. No change will be observed immediately except perhaps under the five hour spot, where a slight hyperæmia will be observed, quickly followed by a hard wheal resembling urticaria. After two or three weeks, however, the one hour spot will show a tender inflamed area which will slowly fade away in one to two months. The two hour spot will show still greater reaction, may go on to vesiculation, and will require a still longer time to heal. The five hour spot will probably go on to ulceration and form a sore which will require three to six months to heal, as was the case in a burn sustained by Professor Curie. So we get, according to the length of exposure, first erythema and congestion, then dermatitis, vesiculation, and finally necrosis and ulceration. If any hair is present it will fall out, but will return unless the burn has been too deep. After healing there may be pigmentation or cicatrization. So the results on living tissue resemble very closely those of the x rays.

Radium produces a sensation of light to eyes which are partially blind, but no effect upon the totally blind. This gave rise at one time to the report that radium would cause the blind to see.

The nervous system of young animals, as mice and guinea pigs, are especially susceptible to the rays, but the same effect is not produced upon full grown animals. A full grown rabbit in St. Luke's Hospital, New York, carried a tube of radium under his skin near the spinal cord for a week or more with no ill effects.

Microscopical Effects.—Dr. Abbe, in a patient to be operated upon for carcinoma of the breast, applied radium to the sound skin, to the cancerous area, and in one place buried the radium within the tumor for several hours. After amputating the breast it was given to Dr. F. C. Wood for examination, and he reports the following effects:

1. On the skin: A superficial necrosis of the cuticle always takes place; the longer the application, the deeper the devitalization of cells.

2. Leucocyte infiltration shows around all vessels and nerves—this accounts for the painful sores.

3. Where an area of cancer underlies the skin, a softening and devitalization of the central cells of "nests" nearest the radium takes place.

4. Where the radium was thrust into the cancer an area of complete destruction of cancer cells for not more than one quarter inch takes place.

A recurrent nodule of cancer was exposed to strong radium twenty times during three months and diminished to one third its former size. It was then excised and upon examination showed marked fibrous hyperplasia among the cancer cells.

Abbe sums up the effect of radium upon cancerous growths as follows: "Those malignant cells which have escaped destruction or retrograde change show a striking *quiescence* which may mean death of the vital force which makes them malignant. In this connection we cannot fail to be reminded of the seeds which fail to grow after exposure to radium.

Radium has been found to be bactericidal, killing *B. typhosus*, *B. of cholera*, and *B. prodigiosus*. It has to be applied very close [$\frac{1}{2}$ mm.] and exposed about twenty-four hours.

Various physiological effects are reported: e. g., oxyhæmoglobin is converted into methæmoglobin. Red cells give up their hæmoglobin to solutions more readily. Emulsin and trypsin are rendered inert (*British Medical Journal*, July 9, 1904). Vaccine is also said to become inert. Seeds produce stunted plants or fail to germinate. It seems that young and rapidly growing cells are most susceptible to radium rays.

Therapeutical Value.—Radium has been found to be of value chiefly along the same line of cases as the x rays. This was to be expected since we notice the similarity of effect upon the healthy skin. It has been used chiefly in the treatment of lupus, superficial and deep cancerous growths, and various skin lesions. I have collected from various sources the following cases and results of radium treatment:

Williams, in the *Medical News*, reports:

Mammary cancers.... 0 cured; 3 improved; 1 unimproved.
Epidermoid cancers...11 cured; 12 improved.
Rodent ulcers..... 2 cured; 3 improved.
Lupus vulgaris..... 4 cured.

Williams also reports 1 keloid improved, 1 psoriasis, 2 chronic eczemas, 9 acne vulgaris, improved or cured.

McLeod, in *British Medical Journal*, reports:

1 Lupus vulgaris cured after 18 exposures.
1 Lupus vulgaris cured after 70 exposures.
1 Lupus verrucosa improved.
1 Rodent ulcer cured after 46 exposures.

In the *Lancet* for April 23, 1904, we find 17 cases of well advanced and secondary carcinoma treated *without* any satisfactory results.

Exner, of Vienna, reports marked improvement in a melanosarcoma, and Abbe reports marked diminution in size of a sarcoma of the lower jaw, and apparent arrest of growth. Exner also reports temporary improvement of symptoms and increase in the calibre of the stricture in three cases of cancer of the œsophagus.

Max Einhorn, of New York, reports nine cases of cancer of the œsophagus treated by radium. The radium was introduced in a capsule on the end of a flexible bougie and kept in contact with the stricture. He calls his instrument a Radiodiaphane. Of nine cases so treated six showed increase in calibre of the stricture and greater ease in taking food. One patient improved markedly in weight. In three cases no improvement was noted, due to irregularity of treatment or to insufficient time having elapsed. Einhorn does not claim to cure, but any relief to these hopeless inoperable cases is to be welcomed as a step forward in treatment.

Lassar, of Berlin, is very enthusiastic over radium in the cure of certain skin lesions; but Bulckley, of New York, says it does not possess any advantages over x rays. Ordinary warts can be cured by one to four exposures of one hour each. "Port wine mark" has been known to become whiter after exposures.

Abbe reports treatment of thirty to forty cases with radium and reports cures in lupus, rodent ulcer, epithelioma, verruca; improvement in symptoms and diminution in size of recurrent carcinomata; some alleviation of symptoms in two cases of carcinoma of cervix uteri; and diminution in size of one giant celled sarcoma of jaw. He says the judicious use of x rays is often more beneficial, but radium is often a valuable adjuvant.

Pusey, of Chicago, says the results of radium are almost if not identical with x rays. The indications for radium are:

1. Inflammatory diseases of the skin: Eczema, psoriasis, lichen planus.
2. Bacterial diseases of skin: Acne, sycosis, lupus vulgaris, blastomyces.
3. To cause destruction of tissue of low resistance, as: Lupus, carcinoma, and sarcoma.

In the *Lancet* for March 26, 1904, are reported two cures of tuberculous ulcers of the throat by twenty minute exposures twice a day. It is also recommended for tuberculosis of superficial bones, as in hand, foot, sternum, and ribs. Radioactive bismuth has been given internally for carcinoma of the œsophagus and stomach; one case of reported improvement. Max Einhorn has been using his radiodiaphane as an aid in diagnosis. He takes the patient into a dark room and inserts the radium into œsophagus and locates it by a fluorescent screen, thus detecting the location of the stricture, or locating the lower border of stomach in dilatation or gastroptosis. He also inserts it per rectum and locates the sigmoid flexure.

CONCLUSIONS.

In radium we have an element of extreme interest to both scientists and the medical profession. Its

action resembles closely that of the x rays: its main advantages being in the ease with which it can be carried around and used, especially in inaccessible mucous cavities, such as the nose, throat, œsophagus, stomach, vagina, and rectum, and its bactericidal power. It is of undoubted value in lupus, rodent ulcer, epitheliomata, some sarcomata, and certain chronic skin diseases. If larger quantities can be produced and the cost diminished, it will surely be of great use to mankind.

The Southside Medical Society, of Virginia, at its meeting in Wakefield on January 3rd, elected officers as follows: President, Dr. W. H. Wallace, of Disputanta, Va.; first vice-president, Dr. Joel Crawford, of Yale, Va.; second vice-president, Dr. W. L. Devany, of Dendron, Va.; third vice-president, Dr. H. B. Mahood, of Emporia, Va.; fourth vice-president, Dr. J. F. Bryant, of Franklin, Va.; treasurer, Dr. R. H. Sims, of Powellton, Va.; recording secretary, Dr. J. E. White, of Wakefield, Va.; corresponding secretary, Dr. R. T. McNair, of Emporia, Va.

The Wyandotte County, Kan., Medical Society, at its meeting in Kansas City, Kan., on January 2nd, elected officers as follows: Dr. John Troutman, president; Dr. C. A. Folks, vice-president; Dr. J. W. May, secretary; Dr. Anna K. Master-son, treasurer.

DIFFERENTIATION IN THE DIAGNOSIS OF NON-DEFORMING CLUB FOOT.

By JOHN JOSEPH NUTT, M. D.,

NEW YORK,

ASSISTANT SURGEON, NEW YORK STATE HOSPITAL FOR CRIP-
PLED AND DEFORMED CHILDREN; ASSISTANT SURGEON,
ORTHOPEDIC DEPARTMENT, CORNELL MEDICAL
COLLEGE DISPENSARY.

The orthopedist has fairly well impressed upon the general surgeon and the family physician the importance of early diagnosis in diseases of the hip joint. Diseases of the knee are frequently, though not as frequently as they should be, referred to the specialist soon after symptoms appear. Diseases of the ankle or tarsal joint, however, may be the cause of the patient seeking many physicians and surgeons before the correct diagnosis is made and proper treatment prescribed. The equinovalgus of the ordinary flat foot is not a difficult matter to diagnosticate, but the frequency with which the patient suffering from non-deforming club foot has been treated persistently for an irresponsible and usually non-existing disease, to be cured speedily upon the correct diagnosis being made, leads to the recognition of the fact that a wider knowledge of the differentiation between other conditions and that of non-deforming club foot are needed throughout the profession.

For the benefit of those who may not be familiar with this condition, I cannot do better than to quote from the surgeon who was the first to describe it: "In non-deforming club foot all the conditions found in certain forms of talipes exist, with the exception of the exaggerated deformity. That is, there is a loss of normal relation between the articulation at the ankle and the muscles which act upon it, involving also in many instances the tarsus, producing a condition which prevents normal flexion at the ankle joint and modified mobility, with slight deformity at the tarsal, metatarsal, and phalangeal articulations." This interference with normal flexion is due to a shortened gastrocnemius, but, as he explains, it is usual to find also some changes in the plantar tissues.

This condition has been treated by the chiropodist, is frequently the cause of the purchase of rubber heels, cork and felt inner soles, arch plates, and elastic stockings, and it has done its full share in increasing the sales of liniments and powders. The failure of physicians to recognize this disease and, therefore, the natural failure of the treatment, is highly responsible for these patients seeking relief wherever relief is promised. Peripheral neuritis, rheumatism, gout, lumbago, sciatica,

neuralgia, and flat foot are among the wrong diagnoses usually made. Peripheral neuritis, rheumatism, gout, and sciatica are the most frequent mistakes. As the anteroposterior arch is preserved, there is no excuse for mistaking it for flat foot, and yet this error is made.

The diagnosis of metatarsalgia, of inflammation of the ankle joint, and more frequently of the mediotarsal joint, as well as osteitis of one or more of the tarsal bones are among the mistakes made.

Under "previous treatment" the histories of these cases treated at the Cornell Dispensary not infrequently read; "Plaster of paris for—weeks without any improvement." "Cast taken of foot and insoles provided, no improvement." "Strapping applied, no improvement." "Treated for disease of the nerves, no improvement." We find articular rheumatism, muscular rheumatism, lumbago, gout, and sciatica in this list of previous diagnosis and treatment. The importance of an early diagnosis of non-deforming club foot is better appreciated when one recalls that not a few of these conditions result in flat foot, to which fact attention was drawn in an article in the *New York Medical Journal*, for May 29, 1897, by Dr. Newton M. Shaffer. The mechanical disadvantage under which the foot is placed by this condition is responsible in many cases for hallux valgus, flattening of the anterior arch, metatarsalgia, corns, bunions, and ingrowing nails. Although in all probability the cause of this disease is some remote trophic lesion with reflex irritability, as has been pointed out by Shaffer and by Sayre in some forms of flat foot, yet the pathological data which have so far been published are not sufficient to establish scientifically the cause of this well known phenomenon. Whatever the prime ætiological factor may be, the condition of the parts is known and easily demonstrable: the gastrocnemius is shortened, the movements at the ankle joint are limited, the relation between the tarsal bones is normal or nearly so and the plantar fascia is dense and always more or less shortened.

Non-deforming club foot may exist for years without any further structural changes taking place. It is usual, however, for one of two results to follow. With a considerable shortening of the gastrocnemius, the plantar fascia likewise is shortened, and an equinus with slight cavus exists; or, if the gastrocnemius is shortened but slightly, the plantar tissue yields to the undue strain, lengthens, and, the mediotarsal joint, thus deprived of this bow string protection, gives way, and flat foot is present. It would seem an easy

matter to differentiate between a non-deforming club foot and a flat foot, and well marked cases do not present any difficulties; but there are instances where mistakes can readily be made. In by far the greater number of flat feet the gastrocnemius is shortened and it is as a result of this that the plantar fascia has become strained and weakened, and the mediotarsal joint has become more and more movable, until in the extreme cases the scaphoid reaches the plantar plane and the calcaneum has been drawn up and the astragalus down.

Where motion has become abnormal at the mediotarsal joint, but the scaphoid has not been subluxated, it is a common mistake to attribute this mediotarsal motion to the ankle joint, and, in measuring dorsal flexion, to diagnosticate the gastrocnemius as of normal length and the foot as flat. Therefore great care is needed in the examination, to distinguish where motion takes place. The calcaneum and the astragalus are so closely bound together that movement in one is almost invariably in the other. Therefore, by tightly grasping the calcaneum, distinction can be made between true and false ankle movements. In both of these conditions a support for the weakened arch is indicated, but if a shortened gastrocnemius is not recognized and therefore not overcome, a cure cannot be expected.

The pain may be of value in this diagnosis. In non-deforming club foot it is usual for the pain to increase by continued use and, frequently, it is not confined to the foot and ankle, but is felt as much or more in the calf of the leg, or back of the knee and thigh, and even as high as the buttocks. In flat foot the pain is usually worse after rest and is generally lessened by use. Sometimes it is so severe upon arising in the morning, that walking or even standing is impossible until passive and gentle exercises have been undergone for one half hour or more.

Anterior metatarsalgia: Morton's neuralgia. Examinations of a sufficient number have not yet been made to permit the offering of any statistics, but it certainly happens very frequently that a shortened gastrocnemius with its attendant evils exists with this disease. The shortened gastrocnemius, and the shortened plantar fascia, would tend to dislocate the metatarsal bones, and this tendency would be increased by the strain placed upon the extensor longus digitorum. It is not so much the confounding of these two diseases, as the neglect to examine for the changed muscular conditions which may exist with metatarsalgia. If both are present, as is often the

case, the treatment of the former brings relief to the latter.

In strain upon the tendo Achillis, full dorsal flexion will be impossible without pain at the point of the lesion, where, also, pressure will produce the maximum pain, and should be easily diagnosticated from non-deforming club foot, as in uncomplicated cases of the latter condition the attempt at full manual dorsal flexion does not cause pain.

Inflammatory diseases of the ankle and mediotarsal joint should be excluded before a diagnosis is made. Mistakes are not likely to happen if ordinary care is observed. In inflammatory disease of the mediotarsal joint, the spasm of muscles, and complete or nearly complete ankylosis may be present. The spasm will be of those muscles which act directly upon the affected articulation or articulations, but there will not be spasm of the soleus or gastrocnemius. Full dorsal flexion of the ankle is usually possible in uncomplicated osteitis of the mediotarsal joint. In an inflammatory disease of the ankle joint, a mistake in the diagnosis could not be made after the disease becomes well defined. The history is of value both in this and disease of the mediotarsal joint, and in inflammations of the tarsal bones. In non-deforming club foot the history dates back to an uncertain period and pain with callosities are the chief, usually the only symptoms. In these inflammatory conditions of the joints and bones, the beginning of the trouble is most frequently asserted to be due to some injury, and the pain is often of less moment to the patient than the lameness.

The most ridiculous mistakes have been made in diagnosing non-deforming club foot as rheumatism, lumbago, sciatica, gout, and neuralgia. There is no excuse for these errors, as they are always due to slipshod methods; no diagnosis having been attempted. It would be well for physicians and surgeons to bear in mind that this disease should be considered in every obscure or unexplained pain in the lower extremity or in the buttocks or small of the back.

The anteroposterior traction shoe of Shaffer must exert some force upon the internal popliteal nerve and part of the relief from pain, due to stretching of the gastrocnemius, may be from the action of the machine upon the nerve fibres, and especially upon the peripheral nerves.

The great variance in the situations of the pain in non-deforming club foot may be accounted for by the fact that the shortened gastrocnemius will be compensated for in one way by one patient, and in another by a second patient.

It is only by the scientific application of a remedy or remedial agent, that results can be obtained which will encourage its further use. The results from the treatment of non-deforming club foot are among the most satisfactory that the surgeon ever encounters, but the careful study of the diagnosis needs much more attention from both physician and surgeon. One may be most faithful and conscientious in stretching a gastrocnemius, but if the pain is due to rheumatism, anti-rheumatic treatment and not the traction shoe is indicated. Rheumatism, lumbago, gout, or sciatica may be present together with a non-deforming club foot, and when the improvement at the ankle joint becomes marked, and these symptoms still persist, other treatment must be added. Never, however, deny a patient with a non-deforming club foot and with a coexisting pain of even probably rheumatic origin, the possibility of being entirely cured by the removal of the former condition.

SIXTY-NINTH STREET AND BROADWAY.

TIC DOULOUREUX AND OTHER NEURALGIAS FROM INTRANASAL AND ACCESSORY SINUS PRESSURES.

By SARGENT F. SNOW, M. D.,

SYRACUSE, N. Y.

The miserable existence of people suffering with tic douloureux, buffeted about as they have been by the dentist, who has extracted all teeth from that half of their face, and the nerve specialist, who has put them through all kinds of hair-standing electrical treatments, not to mention the general practitioner with his array of analgetics, is sufficient to impress us all, and gives me courage to present a brief résumé of my further observations on neuralgic affections of the head.

I say further observations, because, in 1894, under the title of Hemicrania and Other Neuralgic Affections of the Head relieved by Intranasal Surgery,¹ I called attention to the great frequency of painful conditions arising from pressure in the middle turbinate regions. Again, in 1897, under the title of Headaches from Nasal Causes,² thirty cases were reported, giving percentages, etc., of improvement from purely intranasal operations.

I also had the honor, in 1899, to present a paper to the American Laryngological, Rhinological, and Otological Society on Cephalagra and Tic Douloureux from Accessory Sinus Affections. In that paper attention was called to internal sinus pressures as a cause for that dreaded and agonizing

disease known as tic douloureux. Much to my regret, a European trip prevented my being present personally, so the paper was read by title and was soon buried in the *Transactions* of the society.

Time will not permit me to go into detail as to the literature and ætiology of tic douloureux, further than to say that seven have been reported as coming from intranasal sources.

While it is not my intention to deny that there may be cases caused by dental caries, pressure on nerve trunks, etc., in the twenty chronic cases that I have observed and treated, I have seen none that came from such causes, or that required an excision of the nerve to obtain relief. Each and every one had well marked intranasal pressure or a collection within some of the accessory sinuses, more frequently the latter.

Tic douloureux, with its paroxysms, exists in the acute, subacute, and chronic forms, varying from sharp twinges to the three to five minute seizures of supreme agony.

The acute form, as seen by myself, frequently accompanies a cold with sinus accumulation and passes away with abatement of the inflammation or by securing proper nasal drainage.

The subacute form may present an equal degree of pain, but does not clear up with the removal of nasal obstruction; it starts anew upon slight provocation, showing us that a proper outlet must be made from an affected sinus or some nasal pressure demands relief.

With the chronic cases, any or all internal sinus morbid states from pus, granulations and polyps to diseased bone may be expected, and in these chronic cases a most patient, thorough clearing out is our only hope. Local sprays or systemic remedies aid only as they reduce congestion of nasal membranes, prevent bone softening, or improve the general health.

From my experience it would seem that a pain shooting from the bridge of the nose outward and upward indicates an involvement of the anterior ethmoids. A deeper and more intense pain under or behind the eye, and sometimes apparently in the ear or temple, points to the middle and posterior ethmoids; while a still deeper, splitting pain, radiating outward from the centre, sometimes reflected around the anterior third of the lower jaw, is relieved by opening the sphenoid. Accumulations within the maxillary antrum are diognosticated by the localized pain, with sometimes intense muscular tremor and successions of spasms, shaking the head from side to side.

As stated before, it has been my good fortune to see and relieve twenty chronic cases of tic douloureux in the past seven years, by such methods as described, and no line of work has made me feel

¹ New York Medical Journal, March 31, 1894.

² Medical News, July 10, 1897.

more personal gratification. To see the strong and the feeble racked by pains so intense that they stop, clutch their face, moan, and cry out in agony, will excite the sympathy of the most callous surgeon, and I feel like urging a renewal of effort on the part of all, and a most thorough investigation of the upper air passages for aetiological factors.

Another class of neuralgias characterized by steady pains reflected to some portion of the head instead of the face, commonly known as migraine, or sick headache, often arises from nasal pressure.

Within the past three years men have brought forth proofs of the nasal origin that are incontrovertible. While some have probably been disappointed that the removal of a sæptal spur, deviation or enlarged middle turbinate did not clear up all the trouble, it should not be forgotten that, even after such removals, there can still remain a very sensitive state of the membranes; these sensitive membrane lives may come from exposures, constipation, clogged liver, overeating, autointoxication, etc., any or all of them sufficient to cause enough intranasal pressure to bring on again a neuralgic attack.

While we must admit that hemicrania is sometimes caused by eye strain and cerebral tumors, it would not be surprising if the future showed that a large majority of all headaches depended upon an intermediate nasal pressure, which pressure had to be removed before complete relief could be obtained from any plan of treatment. These intermediate nasal pressures may be from only a temporary engorgement of the middle turbinate that at the time of the rhinologist's examination may be absent, but when the engorgement does again come on it is sufficient to throw people of a high nervous organization into an attack of sick headache.

The middle turbinate may seem an innocent body with plenty of room between it and the sæptum or external wall when the patient has just been exercising, but when he is quiet or lies down it becomes enlarged and crowded and then may effectually block all drainage from, and ventilation to, the anterior, middle, and posterior ethmoids, bringing as a consequence varying morbid states and accumulations with attendant neuralgic symptoms. Further than this, while the middle turbinate may present no appearance of enlargement or of being pressed anteriorly, deep probing will show much crowding, against either the sæptum or the outer nasal wall. Pressure on nerve filaments elsewhere in the body causes reflected pain, why not here? In fact, gentlemen, a close observation of the results of intranasal operative work for headaches and neuralgias during the past twelve years has proved the great frequency with which morbid conditions within the upper respiratory tract act as determining factors.

The intense, aggravated forms of headaches char-

acterized by convulsions, rigidity of muscles, etc., as mentioned in the previous paper spoken of, may be termed "cephalagras," and all the cases that I have observed have been in females where a combination of both marked nasal and uterine factors existed.

That many cases of tic douloureux arise from intranasal and sinus pressures is without question. What exact percentage arises from such causes the author cannot state. Statistics for arriving at a definite figure seem hard to obtain. Personally I believe that 80 per cent. would be a modest estimate.

In any event, we have good cause for suspecting and removing either intranasal or sinus pressure in all cases of facial or cranial neuralgia.

BILIARY COLIC WITHOUT GALLSTONES.

By JOHN G. SHELDON, M. D.,

TELLURIDE, COLO.

Biliary colic, sufficiently typical in character to admit of no mistake in its recognition, does not necessarily mean the presence of a stone or other foreign body in the biliary apparatus.

At this time, we cannot say positively that biliary colic is the result, in all cases, of a well known mechanism.

The cases reported and the statements quoted in this paper are presented in support of the theory that biliary colic may be due to contractions of the gall bladder resulting from an occlusion of the cystic duct—either by foreign bodies, inflammatory swellings, flexions, or displacements; and that it is not necessary that a foreign body should be in transit through a duct for the occurrence of biliary colic. It is admitted that a foreign body moving in the cystic or common ducts may produce biliary colic; but the position taken is that typical biliary colic can, and does, occur as the result of other conditions, and that, in these cases, we cannot from the symptoms say that a foreign body is, or is not present.

I.

John B. Murphy (1) says that biliary colic "occurs when a foreign body is being transmitted through a canal the lumen of which is normally smaller than the diameter of the foreign body. It is never due to overdistention and never due to the retention of bile or mucus under pressure. If the foreign body becomes stationary beyond a few hours, the colic ceases so long as the stone does not advance. It is, therefore, due to a foreign body in transit through the ducts."

This positive statement is as positively contradicted by John F. Erdmann (2) in writing on *Surgery of the Gall Bladder and Ducts*. Erdmann states that "it is necessary to eliminate from

our minds the old idea that attacks of pain and periods of inflammation of this viscus are due to the presence of stones, as, not only has this been proved in an experimental sense, but we are meeting constantly cases of marked inflammatory conditions with all the symptoms of stone in which no stones are present upon operating. Naturally for a period of time this practical demonstration was clouded by the haze of the question of presence of calculi at a former time, and that they were expelled before operative interference was undertaken. In more recent years experimental research with controls showed that pain typical of that supposed to be produced by expulsion of stones was or could be due to efforts at expulsion of the contents of an inflamed, or distended and inflamed gall bladder, no matter whether these contents were bile, mucus or pus, stones, or a mixture of all these."

John H. Musser (3) describes symptoms due to acute cholecystitis without the presence of stones, that correspond to typical attacks of biliary colic with infection. Riedel (4) believes that biliary colic is due to inflammatory occlusion of the bile ducts which results in intermittent contractions of the biliary apparatus to overcome the increased tension resulting from the obstruction.

II.

I have found in the literature the reports of 37 cases of biliary colic in which no stones were found at operation or autopsy and in which it was very improbable, from the symptoms and course of the cases, that stones were passed into the intestine. The pain in these cases occurred in paroxysms and could not be distinguished from true gallstone colic. In all of these cases the colic came on suddenly, was very severe, and corresponded to biliary colic caused by gallstones, in the location of the pain and intensity of the attacks. Some of the patients had suffered from repeated attacks. Case IV, reported by Lilienthal (5) had suffered from 16 paroxysms. In a few of the reports mention is made of the pain radiating to the right scapular region, but the majority of the writers make no statements regarding the radiation of the pain. Tenderness over the gall bladder was present in most of the cases suffering from acute cholecystitis, but many times the occurrence of local tenderness was not mentioned. Jaundice occurred in only two of the 37 cases—those reported by Kehr (6) and Lilienthal (5). One of these jaundiced cases showed cicatricial narrowing of the cystic duct with cholangitis; in the other case jaundice resulted from the pressure of an aneurysm of the hepatic artery.

In 32, out of the 37 cases, the condition found at operation or autopsy was acute inflammation of the gall bladder with distention. In these cases no stones were found. In some of them ulcerations and

adhesions were present; and gangrene was occasionally found. In no case did the colic recur after the gall bladder had either been drained or removed.

The 5 cases of biliary colic without gallstones or cholecystitis were as follows: Two cases reported by Krukenberg (7) in which the gall bladders were very movable and somewhat dilated. No stones were found and no acute inflammatory condition was present. Krukenberg thought that the colic was due to the extreme mobility and anchored the gall bladders into the wounds and drained them. Both cases had no further attacks after the operations. Cabot (8) reports two cases of severe biliary colic due to acute flexion of the cystic duct and displacement of the gall bladder. No stones were found. Fixation of the gall bladder and cholecystostomy gave complete relief. H. Kehr (6) reports a case of biliary colic, jaundice, and abdominal tenderness that showed an aneurysm of the hepatic artery compressing the cystic and common ducts. Ligation of the aneurysm and incision of the cystic duct gave complete relief.

The probable cause of the colic in these cases was closure of the cystic duct by inflammatory swelling in 32, closure of the cystic duct by compression in one, and closure of the cystic duct by flexion and displacement of the gall bladder in four.

The clinical histories and the operative and post mortem findings in these cases do not prove anything. They do show, however, that in all probability biliary colic is not always dependent on a stone or other foreign body for its occurrence. They also support the theory that the symptoms of biliary colic result from resistance to the muscular contractions of the gall bladder or bile ducts; and that the contents of the gall bladder, prevented from escaping by closure of the cystic duct, may offer sufficient resistance to the contractions of the gall bladder to produce severe biliary colic.

Lectures and Addresses.

THE PROPER SCOPE OF SCIENTIFIC (SO CALLED EXPERT) TESTIMONY IN TRIALS INVOLVING PHARMACOLOGICAL QUESTIONS.

By SOLOMON SOLIS COHEN, M. D.,

PHILADELPHIA,

PROFESSOR OF CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE.

(Concluded from page 4.)

So much for the one position. Now for the other. To confine ourselves to a chemical illustration, which may have toxicological bearing, let us take Gautier's observation of the presence of arsenic in the normal human body. If this bare statement should be permitted to be made in court in a case in which the presence of arsenic in a given body is the basis of a murder trial, one can see that justice might easily be defeated. If Gautier himself was testifying he would say, as he has written, that arsenic could be found in normal human bodies only by the use of a certain very delicate technique, which I need not here describe; that he had found it only in the ectodermic structures, and chiefly in the thyroid gland; that he had never found it in the normal liver or normal stomach or normal muscles. He would add that even in the thyroid gland, he had found it only in minute quantity—about $\frac{1}{100}$ of a milligramme in the average human thyroid; that is to say, in the proportion of about $\frac{1}{4000000000}$ of the average body weight; so that if by any inconceivable post mortem diffusion the thyroid arsenic should escape into all the tissues it would be in a proportion absolutely beyond detection, the least that he has been able to detect being $\frac{1}{2010000000}$; that

is to say, $\frac{1}{200}$ of a milligramme in 100 grammes of tissue. To translate this into grains, it would take 100 thyroids—or, if diffused, 100 entire human bodies—to yield $\frac{1}{4}$ grain of normal arsenic to Gautier's test; or to follow Gautier's fair statement to the letter, even doubling the assumed quantity of normal arsenic in a cadaver to $\frac{2}{100}$ of a milligramme to allow for possible traces in the skin and its appendages, we should need a mass equal to 50 bodies to give us the $\frac{1}{4}$ grain. A simple arithmetic calculation therefore shows that this observation, whatever may be its physiological importance, has little medicolegal bearing. But the partial expert witness, that is, one who is telling only part of the truth in order to serve one side of the case—might say that Gautier had found arsenic in the normal human body in recognizable quantity and omit to say anything further. Or he might be ignorant of the details, even if the attorney for the prosecution was sufficiently well posted to inquire concerning them on cross-examination; and the whole truth thus failing to be brought out, a partial and therefore false impression would be left on the minds of the jurymen. Again, the widespread distribution of arsenic in nature and art might be testified to by expert witnesses, truthfully in a sense, and yet partially, and therefore untruthfully in the large sense. By such testimony a jury might easily be misled as to the real significance of the facts. For this is all matter of fact, not of opinion, whether or not it be matter of personal observation. While, therefore, the mere circumstance that a witness has not personally observed the fact of science concerning which he is questioned should not bar his testimony, it does seem that courts should exercise considerable caution as to the admission of such testimony, and might rightfully insist, first, that its relevancy to the special cause at trial be established; secondly, that the witness should be required to affirm his familiarity with all the pertinent details of the special facts to be testified to, and furthermore be required to state them, even in the absence of cross-examination. Failure on the part of a witness to make such full statement should then be considered sufficient, if shown, to throw out all his testimony. This rule would at least tend to discourage witnesses from giving partial and misleading testimony.

Another order of testimony given by experts relates to matters purely of opinion. Here the position becomes more difficult both for court and witness.

A pharmacist testifying as a matter of chemical fact that he has found a certain quantity of arsenic or strychnine in a human body, may be asked whether it is sufficient to kill or indicates that there

has been in the body at any time sufficient to kill? The least quantity of arsenic or any other poison necessary to kill a human being should be a matter of fact; it is, however, for many reasons, one of opinion. In the first place, the experiment has never been made under rigorous conditions. In the second place, in most, if not all of the recorded cases of poisoning, alike in those attended with recovery and those ending fatally, either the exact quantity taken is unknown, or it is so large that no estimate of a minimum lethal dose can be based upon it—while in cases of recovery from large doses there has often been evacuant, antidotal, or other treatment. In the third place the individual variations in response to drugs of all kinds are great. Moreover the hearsay element must be large in such opinions. A pharmacist has knowledge of the doses ordinarily prescribed, and from his reading has some knowledge of the symptomatology of drug poisoning; but his observation has not been, like the physician's, of a character that such reading may be assimilated therewith; and there thus seems to be a valid objection to the admission of his answer. Similarly he may be questioned as to the harmfulness of adulterants or preservatives of food. Here again his observation is not of such a character that his answer can be anything more than opinion; and the line of his studies does not ordinarily lend authoritative weight to his opinion on such topics. But the physician occupies a different position in respect to these questions. They form an important part of his studies and are integrated with the whole mass of his knowledge. He is therefore entitled to express an opinion concerning them; and although he may never have deliberately or accidentally poisoned any one with boric acid or salicylic acid, or may never have recognized impure benzoic acid as the cause of stomach and kidney disease in his patients, his opinion that such substances can and do injure the human stomach and kidneys should be accepted in evidence. *Absence of knowledge* on these subjects, should not, moreover, be twisted by an expert witness into *knowledge of absence* of injurious effects.

Other cases, however, present difficulties to a physician asked to give an expert opinion. Thus, on matters of chemistry and pharmacy outside his experience, his opinions are ordinarily of very limited value. But let us also consider cases that may be within his experience.

A physician who has observed a patient during life and has not suspected poisoning may after the death of the patient have his suspicion aroused, and in reflecting upon the symptoms he may see a new significance in them; this suspicion may be confirmed by the post mortem examination and

the chemical analysis. His honest opinion based upon all the facts may then be different from one previously expressed upon partial knowledge or even embodied in a death certificate. Yet unfortunately he is exposed to animadversion because of his change of view. Still more difficult is the question presented in a case of suspected poisoning to a physician who has not seen the living person or the corpse, but is asked to express an opinion on facts described by others as to the nature of symptoms during life, and as to the cause of death. Here the question is one of pure opinion, for the facts are all beyond his knowledge. It is evident that in the absence of complete and careful observation the facts may so be manipulated as to give apparent basis for discrepant opinions. One set of circumstances is made prominent by witnesses for defense, another by witnesses for prosecution. Few, if any, scientifically accurate observations have been made of symptoms. The autopsy may have been defective in various ways. The testimony of witnesses not only on opposite sides, but on the same side may be contradictory or even in certain particulars self-destructive from a scientific viewpoint. The physician may thus be inclined to minimize in his own mind certain testimony, which nevertheless he is called upon in his sworn opinion to give credence to. Evidently when he cannot form a positive opinion, it is his duty to say so, and not to attempt to twist and force dubious or insufficient evidence into the support of a partizan, because partial, view. Again, an expert is forbidden to formulate questions which he is to be called upon to answer, and yet some error in the formulation may apparently color his testimony otherwise than he desires. He must avoid this by formulating his answer so that it shall tell its own story independently of the question, and by limiting his answer so that it may be positive only so far as the facts are positive; and qualified as to uncertainty or probability when the facts so demand.

Many other orders of difficulties affecting expert testimony on pharmacological questions might be stated, but those discussed seem to be the main ones, and perhaps if they can be averted the others will to a large extent disappear.

In addition to the practice of controlled examinations and exhibition of results already alluded to, I have elsewhere suggested a method that would do away with our main difficulties, but this method is not likely to be adopted for many years, if at all. It is too simple and direct. That method is the submission of purely scientific questions to a commission of experts, who shall, in advance

of the jury trial, hear the relevant testimony as to matters of fact, including the methods and results of any scientific examinations, but no mere opinions from witnesses; opinions being put forth by experts frankly appearing as advocates, and arguing upon the testimony submitted. Such a commission could submit to the court a report or reports, which would thus become part of the evidence heard by the jury that has to find the verdict, and before whom no expert should appear as witness.

In the absence of this simple and direct way out of present difficulties, is there any other? Yes, if we, physicians, chemists, and pharmacists, choose to take it. When we are called upon to consider the facts in a given case in order to determine their significance, and what testimony we can give concerning them, we should make certain stipulations, and I may add that there is little difficulty in securing the assent of attorneys to reasonable conditions. An attorney who should refuse his assent, would I judge, be a first class attorney *not* to be associated with. These stipulations are:

1. That there is no obligation to testify or to give counsel involved in the acceptance of a fee to examine papers or otherwise look into the facts. This is, I believe, usually understood.

2. That the nature of the testimony to be given, in case the preliminary examination permits an agreement to testify at all, is subject to modification by the subsequent disclosure of new facts at the trial or otherwise; and that the attorney must then decide for himself whether or not to call one as a witness.

3. That one is to be asked only simple and direct questions permitting the framing of answers that will bring out the whole truth as one sees it, and not merely fragments of the truth.

4. That one is not to be expected to be positive upon uncertain matters, or to throw doubt upon those that are not doubtful.

5. That one is not to be asked questions to which correct answers must be highly technical, and which can therefore only obscure the issue. That, indeed, one is not to be asked such questions for the very purpose of obscuring the issue.

6. That one must be expected to answer frankly all questions by opposing counsel, without reservation or evasion, regardless of the effect of such answers upon the theory of either side.

7. That one is not to be asked irrelevant questions, for the purpose of consuming time or raising clouds of dust; or to be asked to make captious criticisms of the testimony or methods of others; or in any way to be made a party to methods of presentation of facts and opinions, which, however admirable from the viewpoint of an attorney's efforts to serve his client, are opposed to the spirit of truth-seeking science.

It is not to be expected that one can alter the badgering, hectoring, and efforts at confusion

which present juridical standards permit and even applaud in cross-examination. But one can at least refuse to supply ammunition for such practices, to support them, or to countenance them.

A more difficult ethical question than we have yet considered is that presented to a chemist who is called upon to make an analysis of suspected substances. Suppose his analysis reveals the presence of that which the attorney consulting him wishes absent, or *vice versa*. Is he to insist upon being called as a witness? It is no longer a question of testifying—for the attorney will not wish him to do so—but of not testifying. An analogous question is sometimes presented to pathologists. How shall it be decided? Suppose a chemist or a pathologist has been asked to examine the tissues of a person supposed to have been poisoned, for evidences of the poison or its effects? This is not a mere matter of opinion, but of fact. He fails to find such evidence. Or take a somewhat simpler case: suppose a chemist is asked to examine suspected powders or liquids or foodstuffs for the presence of poison and fails to find it. It is possible that his negative testimony might help the accused person. If the public prosecutor nevertheless proceeds to trial, being satisfied upon other grounds that such is his duty, and fails to call the chemist or pathologist who has made the negative finding, is it the latter's duty to volunteer his evidence? The answer to that question is beyond the scope of this paper, but, nevertheless, the question needs to be stated.

SUMMARY OF CONCLUSIONS.

First. The difficulties attending expert evidence upon pharmacological questions could be in large part obviated (*a*) by adopting the principle of *controlled examinations*, with *preservation of portions of materials examined* and *exhibition of material results*; (*b*) by submitting scientific questions to the judgment of a jury or commission of experts who should report to the court and whose unanimous report or discrepant reports should be submitted to the trial jury as part of the evidence in the case. Before such a commission scientific experts might be allowed to appear frankly as advocates arguing upon evidence submitted, but no mere opinions should be given as evidence; it being the function of the commission to formulate opinions for the guidance of the court and jury having final decision of the case.

Second. As the plan suggested in the foregoing paragraph is not likely to be adopted for many years, if ever, the duty devolves upon physicians and pharmacists called as expert witnesses under the present system to guard their own actions and evidence so that the reproach of partizanship and venal interest which now justly or unjustly attaches to the testimony of experts upon pharmacological questions may be removed from the

honest and competent majority and a sharp line of distinction be manifest between them and others.

Third. The chief difficulties that honest, sincere, and competent expert witnesses have to meet are of three orders:

(a) *The necessity to state technical matters in untechnical terms.* There is no way of avoiding this and the expert can only meet it as best he may, deliberately using technical terms when necessary to make the record complete, and afterward explaining them as well as possible in untechnical language.

(b) *The combination of witness and advocate in one person.* This tends to the presentation of partial and therefore partizan testimony, which in the attempt to draw conclusions from insufficient evidence may lead to undue magnification or minimization of certain facts, to the slurring or suppression of material data, to the introduction of irrelevant matters and especially to capricious criticism of the investigations or opinions of others. This can be remedied only by the expert himself.

(c) *The confusion of judgments of fact, the result of scientific research and analysis, with opinions, and like confusion concerning statements of facts of general scientific knowledge.* This can be remedied only by calling the attention of courts and lawyers to the principles involved and thus educating them to a better method.

(d) *The request for formulation of an opinion addressed to one whose studies have not qualified him to speak authoritatively upon the special question involved.* The remedy for this lies exclusively with the expert himself.

Fourth. It is not fair to condemn lawyers for the abuse and misuse of expert evidence, seeing that lawyers can use an expert witness for no purpose which the witness refuses to be used for. Courts may, however—from the viewpoint of scientific investigation—err both in the admission and in the exclusion of expert testimony.

Fifth. Newspapers and the public in general usually do grave injustice to the members of our professions, inasmuch as they do not know how often physicians, chemists, and pharmacists, after examination of the facts in special cases, refuse to testify on behalf of the interests that have consulted them.

Sixth. Physicians and pharmacists asked to give expert testimony should stipulate that they are to tell the whole truth and to answer frankly and fully the questions of counsel on the other side; that they are not to be asked to lend themselves to pettifoggery or obscurity of any kind; that their opinions are to be held subject to modification by any additional facts that may be disclosed; that they are not to become advocates on or off the witness stand.

Seventh. The expert or scientific advocate has an honorable and useful field of work as assistant and adviser to counsel; but his place in court is by the side of counsel, not on the witness stand.

1525 WALNUT STREET.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXV.—What is your experience in the therapeutical use of yeast? (Answers due not later than January 16, 1905.)

XXXVI.—How do you treat bunions? (Answers due not later than February 16, 1905.)

XXXVII.—What diet do you prescribe in typhoid fever? (Answers due not later than March 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but NOT REQUIRED) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the NEW YORK MEDICAL JOURNAL AND PHILADELPHIA MEDICAL JOURNAL (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXIV has been awarded to Dr. Lucien Lofton, of Emporia, Va., whose article appeared on page 26.

PRIZE QUESTION NO. XXXIV.

THE NON-OPERATIVE TREATMENT OF INTERNAL HÆMORRHOIDS.*

Dr. George S. Eveleth, of Little Falls, N. Y., writes:

Patients are prone to group fissures, polypi, fistule, and a prolapsed gut together under the common name of piles; hence the great need of inspection. The non-operative treatment of hæmorrhoids naturally divides itself into two parts, first, the treatment of the acute, and, second, the treatment of the chronic condition. When a patient presents himself for treatment of the acute condition, he is usually suffering much pain, and owing to this fact a proper movement of the bowels has been discouraged. This being so, the first thing indicated is a mild laxative; castor oil, a glass of Friedrichshall, or a dose of sulphur mixed with glycerin will answer. If necessary its laxative action may be aided by a carefully administered enema. If the piles are protruding, as internal hæmorrhoids are likely to at any time, they should be carefully cleansed by cotton wet in a saturated solution of boric acid, lubricated with adrenalin ointment 1 to 1,000, and gentle taxis tried, endeavoring to return first, the last

* Our contributors are correct in supposing that the expression, "without an operation," does not bar out injections.

portion of the gut to come out. If taxis is successful a suppository containing two grains of subsulphate of iron, to which half a grain of opium and extract of belladonna each may be added if there is much pain and tenesmus, should be inserted into the rectum and repeated when necessary; the patient should avoid all muscular effort, be made to use the bed pan, keep his bowels regular, and be cautioned to keep quiet until all pain and soreness are relieved and the tendency to prolapse has passed.

Failing in taxis, the patient should be put to bed, his hips elevated, and a pledget of cotton soaked in a one per cent. solution of cocaine applied to the parts and kept in place by a bag of powdered ice. The ice acts as a sedative and allays the inflammation if used early enough; after the acuteness of the attack is past, an ointment containing one drachm of subsulphate of iron and half a drachm of extract of opium and belladonna each to an ounce of vaseline may be applied. If the case is not seen till later, compresses wrung out in hot water, or a flaxseed poultice to which laudanum and lead water have been added will give more relief than cold applications. If sloughing takes place, more or less of a cure may be expected. A hypodermic injection of morphine may be given at any time if the suffering is not controlled by the measures mentioned. The patient should be kept in bed and made to use a bed pan. A saturated solution of boric acid on cotton should be used as a detergent, and the diet should be restricted.

Bleeding piles may be cured by touching the hæmorrhagic spot with nitric acid. After the subsidence of the acute symptoms, use a suppository containing three grains of extract of *pinus canadensis* and a grain and a half each of hamamelin and hydrastinin. One of these suppositories used morning and night will cure a very large percentage of mild cases and palliate the severe cases.

The very best possible treatment of hæmorrhoids is the preventive treatment. This applies to acute conditions in a degree, but more especially to chronic cases, and in order to best understand and best apply this treatment it is necessary to briefly call to mind a few of the chief causes which make this trouble so common.

Hæmorrhoids are merely varicose veins, whether they are internal or external; whether they are inflamed, infected, or bleeding depends on an added cause besides the mere dilatation of the involved blood vessels.

That the standing posture is operative will be seen in the increased susceptibility of certain oc-

cupations, namely, those of barkeepers, street car conductors, printers, dentists, and the like. Anything that interferes with the return circulation, such as the pressure of tumors or the gravid uterus or anything that renders the circulation sluggish or anything that causes a congested portal circulation, such as overindulgence in alcohol or the excessive use of meats, will bring on piles.

Straining, whether from heavy labor or from coughing or from chronic constipation or from chronic cystitis, an enlarged prostate, a stricture of the urethra, or a stone in the bladder, often brings on hæmorrhoids.

Neglect of local cleanliness and the use of improper detergents also play an important part in causing piles, and especially in aggravating the condition when it already exists.

We know that prolapsed piles become infected readily and that in certain forms of diarrhœa and in dysentery the rectal mucous membrane becomes infected and infiltrated with an inflammatory exudate, which blocks the venous circulation, and that, together with the straining and frequent irritating discharges, causes some of the most troublesome cases we have to deal with. It is not beyond the province of this essay, I assume, to advise surgical treatment of pathological conditions which may cause hæmorrhoids, provided the piles themselves are spared. This being so, tumors, urethral stricture, stone in the bladder, and chronic cystitis, should receive their appropriate surgical treatment.

Alcohol in all forms must be avoided, and tea, coffee, and tobacco used very sparingly or, better, not at all. Meat should only be eaten once a day. Fewer varieties of food should be eaten at each meal and, generally speaking, a less quantity, especially by people of sedentary life.

A cold morning bath, either plunge, sponge, or shower, according to the patient, is helpful as a good general tonic. It equalizes and strengthens the circulation, relieves local congestions, and stimulates peristalsis. Exercise for that class of patients who need it should be light, but systematic, and taken out of doors if possible. Exercises that call the abdominal muscles into action are indicated.

Keep the bowels regular both in regard to the number of movements and in regard to their proper consistence, for it is the lack of this regularity that causes more cases of hæmorrhoids than all other causes combined. Diarrhœa and dysentery should be treated by intestinal antiseptics and astringents and by regulation of diet. Regulation of diet is all important in the treatment of that opposite condition, the greatest single causa-

tive factor in the disease, constipation. The patient should be made to eat less meat and more of the sea foods, less pastry and fine bread, and more of the cereals and rice and coarse bread, more vegetables, and fresh fruits and dried fruits, like figs, dates, and raisins and fruits stewed with little sugar, especially prunes. English walnuts with plenty of salt may take the place of a dessert, and a glass of cold water with half a teaspoonful of table salt before breakfast and at bedtime is a valuable aid.

If the bowels need further help, the natural laxative mineral waters or compounds containing sulphur are valuable. The old Allingham pill always acts well. Cathartics should never be given. There should be a regular time for going to stool and plenty of time to devote to this important function. Just before going to bed is a good time, for there need be no undue haste and then there is plenty of time for an enema if needed, either hot or cold. The hot has the greater decongestive action, and then, too, the recumbent position in bed favors the reduction of the swelling of the piles, which always accompanies defecation.

Dr. Harriett Hooper, of Johnstown, Pa., writes:

Internal hæmorrhoids are very insidious in growth, and often bleeding after defecation is the first sign of their presence that the patient notices. We all know that hæmorrhoids are simply an enlargement of the blood vessels of the rectum, and involve the mucous and submucous tissues. To cure this, relieve the pressure. Therefore dilate the lower rectum, relieve all urinary irritation and in the female all womb pressure, and keep the portal circulation free from all impediment.

In the earlier stages a single dilatation is often sufficient to effect a cure. A steel dilator may be used in the office daily, increasing the widening, but it is better practice to dilate manually at the home of the patient. Give the patient a few drops of chloroform, then insert slowly, one at a time, both thumbs well coated with vaseline into the anus; grasp the buttocks firmly and separate the thumbs. If the patient objects, and he usually does, and will not consent to undergo this, then give him a set of three smooth glass dilators for self-treatment at home. Direct him to use the smallest size, the first day five minutes, the next day ten, and the third day fifteen. Continue the fifteen minutes for five to seven days, then use No. 1 for five minutes, remove and use No. 2 for five minutes, using No. 2 for ten minutes the next day, and then continue as with No. 1. Use No. 3 in the same manner. Usually after

the second week No. 2 can be placed without first using No. 1. By the end of the third week No. 3, which is over two inches and a half in diameter, can be easily retained for fifteen minutes. This will cure unless we have an ulcerative or bleeding mass to deal with. Then follow the use of the dilator daily by the pile pipe. The pile pipe I use is of hard rubber, perforated by numerous small holes through which, as the bottom is screwed up, a healing, astringent ointment is expelled on to all parts of the rectum equally. Zinc ointment has healed many cases. Use opium in the salve for pain. I give sodium phosphate daily for the three weeks of this treatment. When the patient says he cannot use the pipe, I allow him to use an enema of tannic and boracic acids after the dilator. In office treatment, after dilatation, I touch the tumors with fluid extract of hydrastis.

Patients will often consult a physician for inflamed and strangulated hæmorrhoids, which they have been working at unsuccessfully themselves for days. To relieve this condition, place the patient in the knee chest position, cover the protruding mass with cotton soaked in a ten per cent. cocaine solution, then, when they are insensible, cover them with vaseline and insert the finger in the rectum. With the fingers of the other hand press out all the blood possible and rapidly replace the hæmorrhoids in the rectum. If unsuccessful at the first trial, give a hot water enema and repeat. If sloughing has occurred, or is about to take place, use charcoal poultice, followed by touching up with tincture of myrrh or carbolic acid. When the masses are large and the patient will not take home treatment I inject the tumors. I never think of doing this when the tumor is in a state of inflammation, but use hot douches, enemas, sitz baths, and soothing ointments till the congestion subsides. To inject, place the patient on the side, so that the mass is pendent and hangs away from its base; then the fluid will tend not to go upward as readily into the other tissues. Insert the needle midway between apex and middle and inject drop by drop, watching after each to see if the color changes. Use a fifty per cent. carbolic acid solution in oil or distilled water. Never use a weaker solution, for it is painful, and there is danger of its spreading into the surrounding tissues. The strong solution acts as a caustic and anæsthetic, and the resulting slough will end the tumor. A fifty to sixty per cent. solution will coagulate the albumin, forming a firm clot, so that there is no danger of embolism. Withdraw the needle carefully and notice if blood follows; if it does, not enough fluid was injected, so replace it and inject

again. Cover the tumor with vaseline, use an opium suppository, and there will be no pain.

Dr. Samuel D. Rumrill, of Springfield, Mass., writes:

With as little inconvenience to the patient as possible, I get all the previous history, so that I may find the cause, and therefore be better able to correct the morbid process as well as influence or cure associated diseases, which are pre-disposing factors of hæmorrhoids. Examination of the rectum, digitally and through a speculum in a good light, is necessary to ascertain the exact nature of the hæmorrhoids, the presence or absence of fissures, and the extent of proctitis that usually exists. I examine the urine in this class of cases. If in the history evidence of pelvic, hepatic, or cardiac disease is found, an examination of the organ in question should be made.

The first thing we are called upon to do is to alleviate the pain and sometimes to stop the hæmorrhage. A simple formula containing opium or cocaine in the form of an ointment usually is all that is required for the pain. If these fail, the newer analgetic preparations may be tried. Sometimes it is necessary to use hypodermic injections of morphine. A piece of gauze wet with thirty minims of adrenalin chloride, 1:1,000 solution, put into the rectum in apposition with the bleeding surface and allowed to remain there about two hours, is useful to stop the hæmorrhage, and I have noticed in some cases that it alleviated the pain also. When the hæmorrhage is from a small vein or artery, the bleeding point should be caught with forceps and tied with silk.

To correct the morbid process by local applications, it is necessary to put into the hands of the patient or attendant instruments and remedies, all of which must be kept sterile. I give very clear instructions regarding the care and use of these articles, so that there will be no resulting injuries to the anus and rectum. An enema of two ounces of olive oil should be given before every movement and retained as long as possible. After the movement a cleansing enema of soap suds should be given. The external parts should be cleansed with cold water, unless the patient objects very much to cold, when hot may be used. If any piles protrude, they should be anointed with some analgetic astringent ointment and pushed gently back. More of the ointment should be spread on gauze, placed against the anus, and retained with a T bandage. The cleansing and anointing of the external parts should be done three times a day, and after every movement.

For anointing I have used most often the following:

R	Powdered opium.....	20 grains;
	Powdered galls.....	30 grains;
	Lead acetate }	
	Ichthyol.....	½ drachm;
	Petrolatum.....	1 ounce.

M.

During the acute stage the patient should be kept in bed on a light diet. The bowels must be kept open and one or two movements obtained every day. To do this, I begin with twenty minims of fluid extract of rhamnus purshiana every four hours till a result occurs, then continue as often as necessary. If this does not accomplish the desired result, I try sulphur lotum, thirty grains, in a dessertspoonful of syrup or molasses night and morning. I am very careful not to purge my patient, and have seldom had to give anything more active than the above mentioned drugs. When I do I prescribe the phosphate or sulphate of sodium or the sulphate of magnesium. Salol, in five grain doses, three times a day, is useful to render the stools as non-irritating as possible. The diet should be light, nutritious, and of easy digestion. Alcoholic liquors must be prohibited. As soon as the inflammation and pain have subsided the patient may be up and about, the oil enemas and cleansing enemas discontinued, but the cleansing and anointing of the external parts, as well as the salol and cathartic, should be continued for several days. If constipation is the habit, the patient should be carefully instructed in every detail how to avoid this most troublesome condition. If there are any associated diseases, the patient should be warned not to aggravate them, and whenever possible they should be cured.

Bellevue Hospital Training School for Nurses.

—The following young women graduated from this school on January 10th: Sara Agnew, of Florida; Lillian Anderson, of New Jersey; Emily Burns, of Ohio; Margaret Connors, of New York; Edith Feit, of New Jersey; Katherine French, of New York; Mary Kearin, of Massachusetts; Mabel Light, of Wisconsin; Mary McConville, of New York; Gertrude McCutcheon, of Pennsylvania; Elizabeth McConnell, of Pennsylvania; Maud Metcalf, of New York; Jeannette Metzger, of Pennsylvania; Emma Pritchard, of Florida; Charlotte Underhill, Sadie Zetterstorm, of New York.

Wisconsin Medical Union.—Dr. F. X. Schaeffer, of Milwaukee, has been appointed secretary of this union to fill the unexpired term of Dr. R. P. Hansen, of Oshkosh, who has resigned. The office will be moved to Milwaukee.

Correspondence.

LETTER FROM LONDON.

Medical Matters in the Newspapers.—Laxity as to the Incarceration of the Alleged Insane.—An Outbreak of Anthrax.—The Campaign Against Consumption.—The Reported Scarcity of Medicinal Plants.—English and American Hospitals in Continental Europe.—Homes for Aged Nurses.—Hospital Funds and the Medical Schools.—A Tropical Expedition.—Poverty and Distress.—Quack Advertisements.—The Lavoisier Medal.

LONDON, January 2, 1905.

The amount of information in a London newspaper astonishes the visitor. The information is, moreover, condensed, for an American "display head" or a full page "comic" would only impress the English editor as a reckless waste of valuable space. Accuracy is a characteristic, and even the silliest of the London "yellows" would attain a sedate reputation in New York. What surprises me most of all is the abundant medical comment. This is, no doubt, supplied because of a greater and more intelligent interest in medical things than prevails in other places.

The lunacy law is far from perfect. Doubting some recent assertions in the press, I took the trouble to make some inquiries. I discovered, however, that as things stand, a bald assertion as to a person's mental state is all that is necessary to justify a relieving officer in taking such a person for confinement in an insane ward while awaiting examination. A practical joker may thus have any one sequestered for a time at least, after which, here as elsewhere, the unfortunate tendency is to presume the worse until it is disproved.

Recently there have been several cases of anthrax in the Mile End quarter. The centre of infection lay in a horse hair and fibre wareroom. In one case the brother of a horse hair worker became ill and died. A post mortem demonstrated the disease, and subsequent microscopical examination confirmed the diagnosis. The coroner concluded that the germs were conveyed on the person of the worker to his home, where they infected the bedclothing and displayed their virulence on opportunity.

The National Association for the Prevention of Consumption has written to the steamship companies pointing out the great danger of the spread of phthisis from diseased persons to healthy folk on board. The society suggests that the companies, in contracts with passengers, should reserve power to remove consumptives

from cabins to accommodations designed for their special segregation. The idea is good, but it seems to the writer that the general campaign of education in this matter is not being pushed to the same extent in London as is the case in the chief American cities. In New York there is hardly a schoolboy but can give at request all important phases of this question. In Chicago, in San Francisco, much is being done. In Washington, D. C., Charles F. Weller, of the Associated Charities, and Dr. Jesse Ramsburg are giving, year in and year out, two or three free lectures a week throughout the town.

Some sage—name not given—"bursts out of his cell, with a terrible yell" and puts into print the assertion that medicinal herbs are not cultivated as they were a century ago. Beyond parsley, sage, mint, and thyme, the average housewife seems not to care. This is scarcely news, but I am surprised to note that a few old fashioned gardens still contain basil, balm, borage, chamomile, fennel, hyssop, lavender, marjoram, rosemary, rue, and tarragon.

On December 15th the foundation stone of an English hospital was laid in Rome. The hospital is to be erected by the nursing sisters of The Little Company of Mary. This should interest Americans. The English have a hospital in Paris and one in Berlin, while the proposed American hospital in Paris seems to be as far off as ever from realization; unless, indeed, things have changed since my last information.

On December 9th Princess Christian, of Schleswig Holstein, opened in Clapton Square a new settlement for aged nurses. This, it is to be hoped, will be the first of a series of homes for aged nurses who are past work and have a small pension.

At the recent annual meeting of the Metropolitan Hospital Sunday Fund, which was held at the Mansion House, there was a heated controversy over the question of assistance to medical schools. The Honorable Stephen Coleridge moved that no money be assigned to any hospital that contributed to the support of the medical schools or laboratories from its general fund for the relief of patients. The London Hospital, in particular, was adversely commented upon by another speaker for having spent £7,000 on a recreation ground for students. The fact that the land is now worth £10,000 was ignored. The lay governing board is fully as preposterous in England as it is in the United States.

An expedition fitted out by Liverpool merchants is being sent out by the Liverpool School of Tropical Medicine. Professor Boyce, Dr

Evans, Dr. Clarke, Dr. Giles, and Dr. MacConnell are among those on the expedition. Sierra Leone, Gambia, Lagos, the Gold Coast, and Nigeria are fields to be explored. Particular attention, of course, will be given to yellow fever and malaria.

There is fearful distress among the working classes in some of the poorer quarters. In West Ham, in particular, there are 12,000 adult males, of whom 2,000 are unmarried, and 3,000 single women, out of work. In all, 30,000 sufferers are without food. The most pitiable among these are the infants. They are doubly to be pitied because of the appalling ignorance of the low grade British mother. All principles of hygiene are ignored, and cleanliness is uncommon. I have recently made note of a small lodging house in which the street dirt had accumulated on the floors to such an extent as to require, not a broom, but a shovel for its removal. The kitchen floor was covered with sewage. One hundred people lived in the house. Bad food—stale fish, contaminated milk, and half rotten vegetables—are the rule. The costermongers who vend these edibles (?) are haled to court with commendable frequency, though the usual "one month at hard labor" does not seem to be very effective as a preventive of further offenses. Unfortunately, however, one month is the limit of the law.

The English are too fond of hooting to stand for such nonsense as Dowieism, but I shall quote an advertisement: "W——'s Gripe Water. Administered according to directions, the child will be enabled to properly assimilate its food. Should be in every mother's hand."

The Lavoisier gold medal has been awarded to Professor Dewar for his researches in the liquefaction of gases. This medal is awarded by the French Academy of Science.

Therapeutical Notes

Malignant Syphilis.—Sir Alfred Cooper, in the *Practitioner*, for July, 1904, advocates the Zitmann treatment in cases where other methods have failed. It is said to be indicated in cases of severe and rapid ulceration causing much destruction of tissue and general exhaustion. In many cases two weeks' treatment is said to arrest the progress of the disease and bring about rapid healing. The evening before treatment is begun the patient takes 2 grains of calomel, 5 grains of colocynth, and 2 grains of hyoscyamus. The medicine consists of two decoctions. The first contains sarsaparilla root, 4 ounces; aniseed and fennel seed, of each 500 grains; senna leaves, 1 ounce; and liquorice root, 4 ounces. These are bruised and added to 4 gallons of water, together

with 80 grains each of white sugar, alum, and calomel, and 20 grains of red mercury sulphide, enclosed in a linen bag. The water is then boiled down to 1 gallon. The dregs of this are then put into 3 gallons of water with 2 ounces of sarsaparilla root and 1 ounce each of lemon peel, cardamom seed, and liquorice root, and boiled down to 1 gallon. This is decoction No. 2. In the morning the patient drinks one half pint of hot decoction No. 1 at nine, ten, eleven, and twelve o'clock, and in the evening one half pint of cold decoction No. 2 at three, four, five, and six. The patient is kept in bed in a warm room, and the treatment is repeated for four days. On the fifth day the patient gets up and takes a hot bath. In the evening he takes two pills, as at first, and the decoctions are continued on the next day. The treatment lasts fifteen days.

Use of Podophyllin.—Podophyllin, according to *Revue française de médecine et de chirurgie*, for November 21, 1904, is a drug that has very different effects on different subjects, so that its administration should be guarded. One excellent prescription is:

R Podophyllin } of each.....3 centigrammes
Powdered ginger } ($\frac{1}{30}$ grain);
Honey.....a sufficient quantity.

M. For one pill.

Belladonna tends to diminish the irritating action of podophyllin:

R Podophyllin } of each.....2 centigrammes
Extract of belladonna } ($\frac{1}{30}$ grain).
Powdered belladonna root }

M. For one pill; one or two pills daily.

Fluorescent Light in Skin Diseases.—Jesionek, in *Münchener Medizinische Wochenschrift*, for May 10, 31, and June 7, 1904, gives an account of Tapeiner's treatment of skin diseases by means of fluorescent bodies under the action of light. The part to be treated is painted with the fluorescent solution and exposed to light. Sunlight is used when possible; if not, an arc lamp of 220 volts and 25 ampère capacity is used at a distance of 4 to 6 feet. The light is concentrated and the heat rays are intercepted. For eosin, which is the chief fluorescent substance used, a mixture of copper sulphate and picric acid is best. The solution of eosin used is from 0.01 to 0.1 per cent. Jesionek has treated nine cases of rodent ulcer and epithelioma. All cases but one improved; one was cured after two and a half months. Three cases relapsed after improvement.

Cascara Sagrada.—*Revue française de médecine et de chirurgie*, for November 21, 1904, states of this drug that it should be generally taken fasting. It is especially valuable in chronic constipation, its prolonged use does not seem to establish a habit, and it causes no diarrhoea, colic, or nausea. It may be taken as a powder in capsules containing from $3\frac{3}{4}$ to $11\frac{1}{4}$ grains; in the fluid extract, in 20 to 40 drop doses daily by an adult; in compressed tablets from 3 to 6 grains in weight; or in the following pill:

R Extract of cascara sagrada } of each.....10 centigrammes
Powdered cascara } ($1\frac{1}{2}$ grain).

M. For one pill, to be silver coated.

NEW YORK, SATURDAY, JANUARY 14, 1905.

THE DEFECTIVENESS OF WATER WHEN TOO PURE.

The admirable natural fitness of the elements for the purposes which Nature intended then to serve is forcibly illustrated by certain facts going to show the inferiority, indeed the actual harmfulness, of water as a medium for fresh water animals to be surrounded by when it has been rendered as nearly pure as it is possible to make it. For a number of years there have been before the profession accounts of experiments by competent observers tending to establish as a fact the noxiousness of distilled water to certain crustaceans and other fresh water or amphibious animals. But there has been a weak point in these observations, that of the possibility that the effects noted were not merely those of the purity of the water, but those of its contamination by some poisonous substance in the process of distillation. Mr. G. Bullo, of the Rudolph Spreckels Physiological Laboratory of the University of California (*University of California Publications, Physiology*, vol. i, No. 22) has therefore rendered a tangible service to our knowledge by going over the ground again in a very thorough manner.

Mr. Bullo's experiments were made on fresh water crustaceans. He finds distilled water highly prejudicial to these animals under all circumstances,

but particularly when, as a result of the distillation having been conducted in copper vessels, it contains copper even in so minute a proportion as one part in 77,000,000—a fact worth noting in view of the recent proposal to employ copper as an addition to drinking water for bactericidal purposes. This idea of the noxiousness of copper in such experiments had been suggested before, but none the less Mr. Bullo has done well to investigate it anew. Even from glass vessels water takes up a certain amount of the constituents of that material, but Mr. Bullo shows that it is not to such contamination that the noxiousness of the water is attributable; at least he has distilled water in vessels of quartz and platinum, thereby rendering it presumably free of discoverable foreign matter, and has found it still toxic. It seems justifiable to speak of it as actually toxic, and not merely inadequate to its life-giving functions, for Mr. Bullo finds that the greater the amount of distilled water in which his crustaceans are placed the sooner they die. The bearing of such findings on medicine may not be immediate, but it would be foolhardy to say that they will not at some time be felt. All exact knowledge is desirable, and sooner or later most of it is likely to prove useful.

DECHLORINIZATION IN EPILEPSY.

Much attention has been paid of late, particularly in France, to the withholding of sodium chloride as an adjunct to the bromine treatment of epilepsy, as we have before remarked. An important contribution to our knowledge of the subject was made at a recent meeting of the Paris Hospitals Medical Society by M. Jules Voisin, M. Roger Voisin, and M. L. Krantz (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, December 22nd).

These gentlemen had experimented upon thirty epileptics, including both adults and children, allowing them an ordinary diet for a month and dechlorinizing the diet for the following month, alternating the two systems of feeding. During the first month, ordinary diet being allowed, there were among the thirty patients 290 pronounced epileptic attacks and 365 attacks of vertigo; during the second month (without salt) the numbers were 170 and 114; in the third month

(with salt) they were 261 and 216; in the fourth month (without salt) they were 262 and 195; in the fifth month (with salt) they were 213 and 222. It will be seen that there was a notable reduction during the second month, but that the decrease was not maintained in the fourth month.

Dechlorinization in itself, the experimenters find, has no effect on the number of seizures; it simply acts to facilitate the operation of the bromides. But it has a very prejudicial effect on the patients. It so reduces the appetite as practically to lead them to starve themselves, and the result of this is a form of melancholia. During the second month of the experiment they bore up bravely, forcing themselves to take food in the thought that the course pursued was likely to prove of benefit to them, but in the fourth month they broke down and became the prey of mental confusion and various hallucinations of sight, taste, and general sensation and of the delusion that they were being poisoned. In addition, they had dyspepsia, great fatigue, disinclination to work, lumbar pains, and muscular cramps. All this, it is pointed out, is neither the depression of bromism nor the mental impairment produced by epilepsy. Some of the patients were so averse to taking food that they had to be fed forcibly. So far as these experiments go, they certainly seem to show that any advantage as regards the frequency of paroxysms that may be gained by dechlorinization in epilepsy is more than offset by a falling off in the general condition.

THE FREQUENCY OF DIPHThERITIC PARALYSIS.

It is seldom that any subject receives in a periodical such encyclopædic treatment as is given to that of diphtheritic paralysis in an article published in the November and December numbers of the *Practitioner*, by Dr. J. D. Rolleston, of the Grove Fever Hospital of the Metropolitan Asylums Board. From this monograph, which not only reflects the author's observation, but also embodies a digest of many of the more important publications on diphtheria, one may learn much concerning the various features of the disease, but of course it is with the consequent paralysis that the author chiefly deals. In

his consideration of this sequela there is a great deal that is of value to the practitioner, but we can here give attention to only one of its points, that of the frequency with which the paralysis occurs.

There is a want of agreement among writers as to the connection between the severity of the angina and the probability that paralysis will follow. Many eminent observers have thought that paralytic sequelæ were more likely to follow a mild than a severe attack. Rolleston ranges himself with those who maintain the opposite opinion, and he accounts for the discrepancy in a measure by the remark that in the severe cases many of the patients die before the paralysis has had time to declare itself. At least this was the case before the antitoxine treatment came into general use, and the changed results as to life and death that that treatment has brought about account for the apparent greater prevalence of diphtheritic paralysis at the present time. Furthermore, he says that before the days of antitoxine treatment many patients withdrew themselves from medical observation when convalescence was established, and any subsequent paralysis that developed was often too slight to attract the notice of the patient or his friends. It is probable, too, that in many instances definite paralysis was regarded merely as asthenia supervening on a severe illness. Even now, when the whole course of the disease is more closely studied than it formerly was, slight instances of the affection are easily overlooked.

INFECTION OF THE UMBILICUS IN THE NEWLY BORN.

Dr. Audion, in his thesis (Paris, 1901), has contributed greatly to our knowledge of the important subject of umbilical infections of newly born babies, and points out in particular that certain obscure cases of infection, ending in death, may be explained by a very simple inflammation of the umbilicus which perhaps has been cured several days before the death of the child. From long anatomical and physiological studies he establishes a most important fact, which explains the ease with which umbilical infections can arise, namely, that the long and complicated cicatrization of the um-

bilicus requires a variable time according to the individual and the attending circumstances. Until two or three weeks, or even more, have elapsed, it is impossible to be sure that an umbilicus is completely cicatrized, and Audion has frequently found post mortem an incomplete cicatrization in an infant whose umbilicus had appeared to be completely closed for several days. He has also noted in living babies a drop of blood or cloudy serum in the navel several days after an apparent complete closure. After complete cicatrization most careful precautions should be continued, because histological studies have shown that at this time there still remains much friable young tissue which is eminently disposed to become infected and to suppurate. While we may not attribute all diseases of newly born infants to umbilical infection, it is nevertheless true that, pathologically and ætiologically, more attention should be given to it than has been given in the past, and that its study with the microscope may greatly aid the physician in the pathology of disease occurring during the first few weeks of life, thus leading to an efficacious prophylaxis.

The various infections manifest themselves by a group of more or less serious symptoms, according to the severity of the septic process, the ensemble of which, if not characteristic, is at least quite constant. The following forms are met with: Primary putrefaction, or moist gangrene, of the cord gives rise to a peculiar aspect of the organ, which, instead of drying up, or if it has begun to do so, at its free end, remains partly or wholly soft, grayish in color, and moist, and at length becomes fœtid. This phenomenon appears from the second to the fourth day after birth and continues until the cord is surgically removed or until it falls off. This, however, is usually delayed on account of the abnormal moisture of the umbilicus, and many cases of tardy detachment of the cord are merely due to a slight degree of putrefaction arising from a careless dressing, or the vessels, having ruptured at the base, give rise to an extravasation of blood which hinders the process of drying in the stump. The objective phenomena are nearly always accompanied by a more or less considerable rise in temperature. Moist antiseptic dressings are to be employed in the first place, and then dry ones, as this treatment appears to be followed by the best

results. The process, if left to itself, exposes the infant to serious complications from infection of the deeper structures of the umbilical apparatus.

Fungus is occasionally met with, and is formed by the production of a vast amount of inflammatory granulation tissue, the surface of which becomes covered by a purulent exudate, generally fœtid. The friction of the clothing and the inflammatory process prevent cicatrization from taking place. Infection of the umbilical wound may also result in tetanus, a disease which has become infrequent in infants at the present time, but which formerly was common. The same may be said of umbilical erysipelas, or phlegmonous omphalitis, and of gangrene of the umbilicus. One still meets with umbilical blennorrhœa, simple ulceration of the umbilicus, and small subumbilical abscesses, all of which are not usually serious, but may be the source of deeper infection. Phlebitis and arteritis of the umbilicus are the lesions most prone to produce septic processes, and they often pass unnoticed. There are, however, certain accidents arising from the changes in the vessels, such as late umbilical hæmorrhage, which, so often due to hæmophilia, to hereditary syphilis, and to a kind of hereditary family predisposition, have been recently observed by Boissard.

Démelin, in his excellent article on umbilical hæmorrhages, classifies those occurring secondarily or spontaneously into: 1. Hæmorrhage due to arteritis arising at about the time the cord falls off. 2. Those occurring in acute degeneration of the infant, with icterus of infective origin. 3. Those in the septicæmia of the newly born, which are produced by the same mechanism as in cases of congenital syphilis following umbilical inflammation, then periphlebitis and endophlebitis, with septic foci in the liver, spleen, etc. Certain infectious foci, such as osteomyelitis, may be attributed to this type of septicæmia.

The researches of Lesage, Démelin, and Boissard on the infectious origin of icterus in infants have shown that the umbilical wound is one of the open doors for the reception of the bacteria, while, according to Durante and Audion, hepatic infection of umbilical origin may, in a weak infant, only present the mildest symptoms and simply mark a step in the slow course of a latent but fatal septicæmia the nature of which is as yet unknown and its symp-

tomatology vague. This septicæmia may perhaps explain the bronchopneumonia, the intestinal lesions, and slight pericarditis, characterized by the presence of a small amount of light yellow liquid in the pericardium and a few lesions of the endocardium, the origin of which is frequently unknown. Microscopic pathological anatomy, aided by well conducted bacteriological investigations, can alone solve the problem.

The therapeutic conclusion from all this means a most careful antiseptis in the treatment of the umbilicus, both before and after the cord has fallen off, and it should be continued for some time after cicatrization has appeared to have become complete. In order to facilitate the dressings and do away with the ligature, which is a frequent source of infection, Porak has devised an omphalotribe, a kind of clamp which crushes the cord, instead of ligating it. Desiccation takes place more rapidly, but this procedure does not enable us to dispense with antiseptic precautions.

CHARLES GREENE CUMSTON.

LARYNGEAL NEURITIS.

Neuritis laryngea is the name given by Boenninghaus (*Deutsche medizinische Wochenschrift*, 1904, No. 46; *Berliner klinische Wochenschrift*, December 12th) to a painful affection of the neck associated by him with laryngeal catarrh. It is characterized by two points of tenderness on pressure. One of them is situated between the hyoid bone and the thyroid cartilage, and the other immediately above the clavicle, close to the trachea, points corresponding to the emergence of a branch of the superior laryngeal nerve through the thyrohyoid membrane and to that of the inferior laryngeal nerve. The catarrh, though probably the starting point of the neuralgia, seems to be trifling in comparison with the severity of the external pain. Massage of the neck has proved very helpful in this affection, but the catarrh also calls for treatment.

AN ALLEGED DANGER IN SEALING WAX.

A Russian physician, Dr. Flaczynski (*Petersburger medizinische Wochenschrift*, 1904, No. 32; *Berliner klinische Wochenschrift*, December 12th), thinks that the continuous use of sealing wax in such places as post offices and express offices is fraught with danger to the health of the employees, since the materials with which it is colored

are often poisonous and to some extent they are vaporized by the flame employed.

ONCOLOGY.

A hospital devoted to the study and treatment of tumors—especially the malignant tumors, we infer—has recently been opened in Philadelphia. The medical staff includes Dr. Boardman Reed, Dr. Addinell Hewson, Dr. G. Betton Massey, and Dr. Howard R. Swayne. This personnel seems to warrant the prediction that the new institution will do good work in the field to which it is devoted.

Obituary.

CHURCHILL CARMALT, M. D.,
OF NEW YORK.

In the recent death of Dr. Carmalt, as the result of a brief illness, the career of a very promising practitioner has been cut short comparatively early in its course. We cannot well spare such men from the ranks of the profession, and the loss of Dr. Carmalt will be seriously felt by his colleagues.

Concerning the Results Which Attend the Leaving of Gauze Compresses in the Abdominal Cavity.—Riese, in *Fortschritte der Medizin*, for October 1, 1904, reports two cases which illustrate the outcome of such accidents as are mentioned in the above title. In the first case the compress penetrated the small intestine and induced phenomena of ileus from obstruction. An operation was performed and the remarkable situation was at once revealed. In the second case there was cystic encapsulation of the compress in the mesentery of the sigmoid flexure. The symptoms were diarrhoea and the sensation of the presence of a foreign body in the peritoneal cavity. The evidence of an abdominal tumor led to the erroneous diagnosis of intraligamentous cyst of the ovary, the abdomen was opened, and the true condition revealed.

The author has been able to collect from the literature of the subject 41 cases in which this accident has occurred, and in which there have been four varieties of results. Peritonitis has occurred with least frequency if the operation was an aseptic one. A more frequent outcome has been the formation of an abscess of the abdominal wall through which or through the vagina the compress has been extended. The third variety was encapsulation of the foreign body, and the fourth the penetration of the intestine by the compress from which it was expelled through the anus, or was retained within the intestine. There are various reports in regard to the frequency of this accident. At the Warsaw Hospital it occurred ten times in 1,000 abdominal sections. To the author it has occurred twice in 900 abdominal operations.

News Items.

Society Meetings for the Coming Week:

MONDAY, January 16th.—New York Academy of Medicine (Section in Ophthalmology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, January 17th.—New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y. (annual); Baltimore Academy of Medicine.

WEDNESDAY, January 18th.—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery (private); Woman's Medical Association (New York Academy of Medicine); Medicolegal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, January 19th.—New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, January 20th.—New York East Side Physicians' Association; Manhattan Medical and Surgical Society (private); New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

Change of Address.—Dr. R. Harcourt Anderson, to 252 Madison Avenue; telephone, 1832 38th Street.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 7, 1905:

	December 31.	January 7.
Cases.	Deaths.	Cases. Deaths.
Measles	126	6
Diphtheria and croup	292	45
Scarlet fever	206	16
Smallpox
Chickenpox	87	138
Tuberculosis	434	282
Typhoid fever	32	7
Cerebrospinal meningitis	18	..
	1,207	226
		1,116

City Hospital, New York.—At the annual meeting of the medical board of the City Hospital, Blackwell's Island, Dr. Edward S. Peck resigned the position of visiting surgeon to the eye division, after an uninterrupted service of over twenty-five years. Dr. Peck has been appointed consulting surgeon to the same division.

The Society of Medical Jurisprudence.—At a meeting of this society, held at the Academy of Medicine, on January 6th, the papers were: The Society of Medical Jurisprudence, Its Progress, Prospects, and Importance, by the retiring president, Mr. Theodore Sutro; The Importance of Medical Jurisprudence for the Physician, by the president elect, Dr. Carl Beck.

Many Pneumonia Cases in Bellevue.—It is stated that Bellevue Hospital is crowded to overflowing with cases of pneumonia, bronchitis, and influenza. About fifty patients have to sleep on spring mattresses on the floor. Some relief is ex-

pected to be had on January 25th for this overcrowded condition, when four portable buildings, each holding thirty patients, will be erected.

Nursery and Child's Hospital.—The annual charity ball in behalf of the Nursery and Child's Hospital takes place on February 2nd at the Waldorf-Astoria. Owing to the loss sustained through the burning of the administration building at the country branch on Staten Island, there will be an unusual need of funds this year by the hospital. Boxes and tickets for the ball may be purchased of Mrs. F. N. Goddard, No. 33 East Fiftieth Street, daily, from 11 to 1 o'clock.

Two New Fakirs "Working" the Profession.—We have been requested to warn physicians against "Dr. Gustave Alexander," who is collecting money under false pretences. There is also "Mr. Litke," whose specialty is representing himself as the agent of a benefit organization, engaging his professional victim as medical officer of his society, and then attempting to collect a proposition fee. Telephoning to the nearest police station is a good measure when approached by these persons.

The Society of the New York Hospital.—Several additional physicians are needed in the class of genitourinary diseases in the male, which meets at the House of Relief, 67 Hudson Street, every Tuesday and Friday night at 8 o'clock. The number of patients averages over 75 each night, and constitutes a very instructive clinic for the study of this specialty. Physicians who are interested in venereal diseases, and who are willing to attend faithfully, will receive regular, but unofficial, appointment upon application to Victor C. Pedersen, M. D., 16 West Sixty-first Street.

The New York Academy of Medicine.—The section in medicine will meet on Tuesday, January 17th, at 8.15 p. m. Order: Presentation of Cases and Specimens; Clinical Reports: (a) Case of Muscular Insufficiency of the Heart with Gross and Microscopical Findings, by Bond Stow, M. D.; (b) Four Cases of Exophthalmic Goitre in One Family, by John J. Cotter, M. D.; paper: The Treatment of High Bloodpressure, by George B. Wallace, M. D. Discussion. Charles H. Lewis, M. D., chairman. E. E. Smith, M. D., secretary, 26 East Twenty-ninth Street.

Medicolegal Society.—The Medicolegal Society will give a complimentary dinner for ex-Justice D. Cady Herrick and ex-Justice John J. Freedman on January 18th on the occasion of the annual dinner and installation of officers of the society. A large number of prominent guests will be invited. Members of the bar who are not members of the society desiring to unite in this tribute to the justices may send their names and addresses to Clark Bell, president of the society, or Dr. A. P. Grinnell, chairman of the committee of arrangements, No. 500 Fifth Avenue.

New York State Medical Association.—This association will hold a stated meeting on Monday, January 16th, at 8 p. m. Programme: Executive session; Scientific session; presentation of clin-

ical cases or reports, pathological specimens, new instruments, etc. Papers: Health of the Nation, by Walter Wyman, M. D.; Health of the State, by Daniel Lewis, M. D.; Health of the City, by Thomas Darlington, M. D.; Health of the Port, by Alvah H. Doty, M. D.; discussion by Dr. George P. Fowler, Dr. Edward Janeway, Dr. A. Jacobi, Dr. J. B. Cosby, Dr. Hermann Biggs, Dr. Ernst Lederle.

PHILADELPHIA.

Pathological Society.—The annual exhibition meeting of the Pathological Society of Philadelphia was held in the Mutter Museum of the College of Physicians on January 11th and 12th.

St. Mary's Hospital, Philadelphia.—The annual meeting of the staff of St. Mary's Hospital was held in the hospital building, Frankford Avenue and Palmer Street, on January 3rd.

Marriage.—Dr. William Pepper and Miss Mary Godfrey were married in St. James's Episcopal Church on December 31, 1904, at noon. Dr. and Mrs. Pepper will reside at 1813 Spruce Street.

Report of Mary J. Drexel Home.—The annual report of the Children's Hospital of the Mary J. Drexel Home shows that 573 patients were treated during 1904. There were 340 free patients and 381 surgical operations.

Personal.—Miss Margaret Pridham, for the past two years directress of nurses in the Medico-Chirurgical Hospital, has resigned, the resignation to take effect on February 1st. On that date Miss Pridham will enter upon the duties of directress of nurses in the Jewish Hospital.

Dr. Benjamin Lee, secretary of the Pennsylvania State Board of Health, sailed for Havana on January 5th to attend the thirty-second annual meeting of the American Public Health Association.

Dr. Horace Jayne has resigned as director of the Wistar Institute of Anatomy and Biology of the University of Pennsylvania.

Obstetrical Society.—At the meeting of the Philadelphia Obstetrical Society, held January 5th, Dr. J. Clarence Webster, professor of obstetrics in the University of Chicago, delivered an address on A Consideration of Fibroid Tumors of the Uterus, Based Upon a Study of a Series of Cases Treated Surgically. The discussion was opened by Dr. E. E. Montgomery, and continued by Dr. John B. Deaver, Dr. Barton Cooke Hirst, Dr. Charles P. Noble, Dr. J. M. Baldy, Dr. John G. Clark, and Dr. W. Easterly Ashton.

Hospital Trustees Elected.—Contributors to the Episcopal Hospital met in the Church House on January 4th and elected these managers: The Reverend Dr. J. D. Newlin, the Reverend J. B. Harding, the Reverend Dr. William B. Bodine, William Platt Pepper, James Logan Fisher, Dr. Wharton Sinkler, H. B. Coxé, Jr., and C. S. W. Packard.

Alfred Moore, a lawyer and a member of the Board of City Trusts, was elected a trustee of the Jefferson Hospital, vice Judge Michael Arnold, deceased, on January 4th.

Section in General Medicine, College of Physicians.—The following was the programme of the section in general medicine of the College of Physicians, Monday, January 9th: Dr. Herman B. Allyn, The Use of Theosin and Theosin Sodium Acetate as Diuretics; Dr. J. H. W. Rhein, The Pathological Study of Acute Myelitis; Report of Two Cases; Dr. J. Alison Scott, A Study of Fifty Cases of Perforation in Typhoid Fever, with Conclusions Based on Ten or More Cases Supposed to be Perforative, but Proved Otherwise; Dr. John M. Cruice, Sarcoma of the Liver.

Hospital for the Study of Malignant Disease.—The Oncologic Hospital opened its new hospital and dispensary, for the study and treatment of cancer, at Forty-fifth and Chestnut Streets, on January 4th. The dispensary service will be held at 2 o'clock daily. The hospital can accommodate 24 patients at present. Dr. Boardman Reed is the attending physician. Dr. Addinell Hewson, Dr. G. Betton Massey, and Dr. Howard R. Swayne are the attending surgeons. Dr. William S. Newcomet is in charge of the x ray department.

Scientific Society Meetings for the Week Ending January 21, 1905.—Monday, January 16th, Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, January 17th, Section on Ophthalmology, College of Physicians; Dermatological Society; Academy of Natural Sciences. Wednesday, January 18th, Philadelphia County Medical Society (business meeting, private); Section in Otology and Laryngology, College of Physicians. Friday, January 20th, University of Pennsylvania Medical Society; American Philosophical Society.

Charitable Bequests.—By the will of William McFarrick, a liquor dealer, who died December 14th, the residuary estate, on the death of the widow and her sister-in-law, will be divided among the Presbyterian, Episcopal, Methodist, and Howard Hospitals for the establishment of free beds. The will requests the widow to give a sufficient amount to St. Agnes's Hospital to establish a free bed.

In the Orphan's Court on January 5th, Judge Ashman awarded a balance of \$52,629.23 for distribution. From this amount the Presbyterian Hospital receives \$5,000 for the maintenance of a free bed.

The Southern Dispensary, Philadelphia.—At the annual meeting of the Southern Dispensary, 318 Bainbridge Street, held January 4th, the following officers and managers were elected: President, John L. Thompson; secretary, Clement R. Bowen; treasurer, Paul J. Field; resident apothecary, W. W. Seary; managers, George W. Prile, John L. Thompson, Dr. N. Hickman, David Jameson, Dr. W. Joseph Hearn, Clement R. Brown, John Middleton, Paul J. Field, Dr. E. Filson Ward, Joseph A. Robbins, George May, and Charles J. Thomson. In the last year 8,092 cases were treated and 14,474 prescriptions compounded.

College of Physicians.—At the meeting of the College of Physicians held January 4th the honorary librarian reported sixty-eight volumes added to the library during December. Dr. James M. Anders read a memoir of the late Dr. F. Savary Pearce. The following officers and committees were elected for 1905:

President, Dr. Arthur V. Meigs; vice-president, Dr. James Tyson; censors, Dr. Richard A. Cleemann, Dr. S. Weir Mitchell, Dr. Horace Y. Evans, Dr. Louis Starr; secretary, Dr. Thomas R. Neilson; treasurer, Dr. Richard H. Harte; honorary librarian, Dr. Frederick P. Henry; councillor, to serve until January, 1908, Dr. De Forest Willard; committee of publication, Dr. G. G. Davis, Dr. Thompson S. Westcott, Dr. William Zentmayer; library committee, Dr. George C. Harlan, Dr. Francis X. Dercum, Dr. Charles A. Oliver, Dr. William J. Taylor, Dr. S. Weir Mitchell; committee on Mütter Museum, Dr. John H. Brinton, Dr. George McClellan, Dr. J. Alison Scott; hall committee, Dr. John K. Mitchell, Dr. Thomas H. Fenton, Dr. B. Alex. Randall, Dr. E. Hollingsworth Siter, Dr. A. O. J. Kelly; committee on directory for nurses, Dr. Wharton Sinkler, Dr. James C. Wilson, Dr. James V. Ingham.

The Health of the City.—During the week ending December 31, 1904, the following cases of transmissible diseases were reported to the bureau of health:

	Cases.	Deaths.
Malarial fever.....	1	0
Typhoid fever.....	73	11
Scarlet fever.....	64	2
Chickenpox.....	30	0
Diphtheria.....	86	10
Cerebrospinal meningitis.....	2	1
Measles.....	14	0
Whooping cough.....	8	2
Tuberculosis of the lungs.....	31	40
Pneumonia.....	71	69
Erysipelas.....	11	2
Puerperal fever.....	1	1

The total death rate for the week was 497, in an estimated population of 1,408,154, corresponding to an annual death rate of 18.36 per 1,000 population. The total infant mortality was 112; 97 under one year and 15 between one and two years of age. There were 36 still births; 25 males and 11 females. The following deaths from other transmissible diseases were reported: tuberculosis, other than tuberculosis of the lungs, 9; dysentery, 2; diarrhoea and enteritis under two years, 14. The temperature for the week was variable; on the 25th the thermometer registered from 18° to 24°; on the 28th, from 54° to 24°; on the 31st, from 53° to 32°. The humidity was high, as a rule. Snow fell on the 25th, and rain fell on the 26th and 27th.

Activity of the Coroner's Office for 1904.—

During 1904, 3,467 inquests were held by the coroner of Philadelphia county; 1,065 of the victims were killed by railroad accidents, injuries by falls, being run over by vehicles, caught in machinery, crushed by elevators, etc. Of the remaining cases investigated by the coroner 448 were victims of heart disease, 209 were suicides, 148 died of burns or scalds, 99 were drowned, 43 homicides, 52 were victims of gunshot wounds, 156 were asphyxiated, 38 died from malpractice, 21 were poisoned, 9 died from tetanus, 6 from electric shock, 2 from heat stroke, and one was struck by lightning.

Northern Medical Association.—The following was the programme of the Northern Medical Association at its meeting held January 13th: Dr.

John K. Knorr, Jr., The Treatment of Adenoids; Dr. T. R. Currie, Address of the Retiring President. The following officers were elected: President, Dr. Albert Bernheim; vice-president, Dr. Howard D. Geisler; recording secretary, Dr. B. L. Singer; corresponding secretary, Dr. Thomas Shriner; treasurer, Dr. John W. Millick; librarian, Dr. R. J. Hess; censor, Dr. I. P. Strittmatter.

Deaths.—Dr. Martin L. Yost, of Allentown, Pa., was struck by a trolley car, while driving, on the afternoon of December 3rd, and almost instantly killed.

Dr. Lyman Leavitt, a graduate of the Pennsylvania Medical College in 1856, died on December 30, 1904, at Trenton, N. J., aged 74 years.

Dr. Henry Clay Clark died at his home in Woodbury, N. J., on December 27th, aged 74 years. Dr. Clark graduated from the medical department of the University of Pennsylvania in 1853. Dr. Clark was appointed assistant surgeon of the Second Regiment, New Jersey Volunteers, in 1861, and was taken prisoner at the second battle of Bull Run.

Dr. Homer J. Doucet was buried from 2604 North Eleventh Street on December 24th. Dr. Doucet was born in France, and received his medical education in that country. He was the author of several books on socialism. He was 84 years of age.

Dr. Frederick H. Griffin died from inhaling illuminating gas on January 1st. Dr. Griffin graduated from the medical department of the University of Pennsylvania. He was about 47 years old.

Dr. Jacob P. Bixler died at his home in Carlisle, Pa., on December 3rd from cerebral hemorrhage, at the age of 65 years. Dr. Bixler graduated from the Jefferson Medical College in 1866, and has been an active practitioner ever since. He was a member of the Medical Society of the State of Pennsylvania and of the Cumberland County Medical Society.

Dr. Samuel K. Barndt died at his home in Alburtis, Pa., on December 7th, aged 62 years. Dr. Barndt graduated from the Jefferson Medical College in 1863.

Dr. Edith Barker, for five years pathologist to the State Asylum for the Insane at Norristown, died recently. Dr. Barker graduated from the Woman's Medical College of Pennsylvania in 1897.

GENERAL

Dr. John Frick, of Memphis, has been placed in charge of the Public Health and Marine Hospital Service at Laredo, Tex. He has been connected with the service for nearly six years.

Dr. C. N. Raymond, of Rehoboth, Mass., was assaulted on the evening of December 31st and severely injured. It is believed that his assailant has been apprehended.

Dr. G. E. Seaman has resigned his position as assistant health commissioner of Milwaukee. It is believed that Dr. Louis Tuldner will succeed Dr. Seaman.

Emergency Hospital, Milwaukee.—Dr. W. F. Darling has resigned his position as senior interne of this hospital, and will probably be succeeded by Dr. C. E. Oberton, whose place will be filled by Dr. Ralph Pearis.

Corning, N. Y., Medical Association.—The annual meeting of this association was held at the St. James Hotel, Corning, N. Y., January 9th. Regular meetings are held on the second Monday of every month. Edward H. Hutton, M. D., secretary.

Requests to Paterson, N. J., Charities.—The will of Mary E. Rile, which was filed on January 5th, gives \$20,000 to the Paterson General Hospital, \$10,000 to the Paterson Orphan Asylum, and \$5,000 each to the Old Ladies' Home and Children's Day Nursery.

Maryland State Board of Health.—Dr. John S. Fulton, secretary of this board, was recently presented with a handsome silver tea service in recognition of his work in the cause of public health. Dr. Fulton is expected to attend the meeting of the American Public Health Association, at Havana, Cuba.

The New Health Board of Middletown, N. Y.—This new board, which was organized on January 3rd, proceeded to elect the following officers: President, Mayor Hornbeck; vice-president, C. C. Lutes; health officer, Dr. J. L. Hanmer; sanitary inspector, Z. K. Greene; registrar of vital statistics, John G. Gray.

El Paso County, Colo., Medical Society.—The officers of this society elected for the year 1905 are as follows: Dr. James A. Patterson, president; Dr. H. W. Hoagland, vice-president; Dr. M. P. Reynolds, secretary; Dr. Daniel J. Scully, treasurer; and Dr. W. H. Swan and Dr. R. K. Hutchings, delegates to the State society.

The Teller County, Colo., Medical Society has elected the following officers to serve until July, 1905: President, Dr. W. P. Pennock, of Cripple Creek; vice-presidents, Dr. W. A. Latimer, of Victor; Dr. B. F. Jones, of Goldfield, and Dr. J. A. McIntyre, of Florissant; secretary, Dr. H. G. Thomas, of Victor; and treasurer, Dr. J. A. Dunwoody.

Graduate Nurses' Association of the State of Pennsylvania.—A special meeting of this association was held in Pittsburgh, Pa., December 17, 1904. The bill for registration, which was read by the committee to the members present, was adopted, and will be presented to the legislature during the present session.

The Western Surgical and Gynecological Association elected the following officers at Milwaukee on December 29th: President, Dr. H. D. Niles, of Salt Lake City; first vice-president, Dr. E. W. Andrews, of Chicago; second vice-president, Dr. R. Grant, of Denver; secretary treasurer, Dr. B. B. Davis, of Omaha; executive council, Dr. C. H. Mayo, Dr. J. E. Moore, Dr. C. W. Oviatt, Dr. Van Buren Knott, and Dr. A. H. Ferguson. The next meeting will be at Kansas City.

Statement of Mortality in Chicago for the Week Ending December 31, 1904, compared with the preceding week and with the corresponding week of 1903:

	Dec. 31, 1904.	Dec. 24, 1904.	Jan. 2, 1904.
Total deaths, all causes.....	654	548	1,165
Annual death rate per 1,000.....	17.68	14.83	32.41
By sexes—			
Males.....	364	293	325
Females.....	290	252	279
By ages—			
Under 1 year.....	119	94	97
Between 1 and 5 years.....	48	55	54
Over 60 years.....	133	126	148
Important causes of death—			
Acute intestinal diseases.....	20	21	15
Apoplexy.....	12	23	13
Bright's disease.....	42	37	52
Bronchitis.....	31	21	28
Consumption.....	68	63	56
Cancer.....	23	31	16
Convulsions.....	14	11	15
Diphtheria.....	15	14	11
Heart diseases.....	48	40	42
Influenza.....	15	1	5
Measles.....	5	0	0
Nervous diseases.....	31	22	23
Pneumonia.....	144	114	146
Scarlet fever.....	2	0	3
Suicide.....	6	8	8
Smallpox.....	3	4	0
Typhoid fever.....	15	6	8
Violence (other than suicide).....	32	26	59
Whooping cough.....	9	7	1
All other causes.....	120	101	127

Statement of mortality for the week ending January 7, 1905, compared with the preceding week and with the corresponding week of 1904:

	Jan. 7, 1905.	Dec. 31, 1904.	Jan. 9, 1904.
Total deaths, all causes.....	542	654	516
Annual death rate per 1,000.....	14.19	17.68	13.95
By sexes—			
Males.....	303	364	270
Females.....	239	290	246
By ages—			
Under 1 year.....	110	119	109
Between 1 and 5 years.....	48	48	36
Over 60 years.....	121	153	110
Important causes of death—			
Acute intestinal diseases.....	13	20	17
Apoplexy.....	12	12	16
Bright's disease.....	36	32	38
Bronchitis.....	24	21	20
Consumption.....	41	68	44
Cancer.....	18	23	22

Violence (other than suicide).....	32	32	30
Whooping cough.....	11	7	6
All other causes.....	111	120	110

Pneumonia and Influenza in Chicago.—The infections of pneumonia and influenza are everywhere prevalent in Chicago, intensified in virulence by the arid state of the atmosphere and by the deficiency of sunshine in December. To a great extent this is also true of the germs of all the infectious and contagious diseases. But the health department is powerless to obtain belief in its predictions or to induce effort to avert the impending—nay, to check the present storm. Mothers continue to expose their offspring to the contagion of diphtheria, measles, scarlet fever, and whooping cough. Adults continue to ignore the warnings of a "chill," try to "fight off" an attack of grippe, and commit excesses of various kinds inciting to serious disease, and too many physicians themselves still ignore the repeated offers of the department to assist in their diagnosis of the bacterial diseases. A striking instance of the evil resulting from this neglect of bacterial diagnosis is seen in the increasing number of reported

deaths from typhoid fever. This is the season of steadily decreasing deaths from this disease and for many weeks the average number has been less than 7 per week. But between December 25th and 31st, there were 15 deaths reported from typhoid. There is good ground for belief that one half the deaths so reported were caused by intestinal influenza and not by typhoid fever. A number of cases have come under the observation of the medical men of the department which were being treated for typhoid fever, but a bacterial examination showed an entire absence of the typhoid bacillus and an abundant growth of the influenza organism. A change of treatment from that for typhoid to that for influenza resulted in prompt improvement and ultimate recovery. The department renews its proffer of the services of the laboratory to all Chicago physicians in the diagnosis of the bacterial diseases by the test tube and the microscope.

Health in Michigan During December, 1904.—Reports to the State Board of Health, by representative physicians in active general practice in different parts of the State, show the diseases which caused the most sickness in Michigan during the month of December (four weeks ending December 31st), 1904, to be as follows:

Diseases arranged in order of greatest prevalence in this month.	Number of reports received for this month.		Per cent. of reports stating presence of disease.		Average for ten years, 1894-1903.	
	Dec., 1904.	Nov., 1904.	Dec., 1904.	Nov., 1904.	Dec., 1904.	Nov., 1904.
Rheumatism	56	36	64	59	64	59
Neuralgia	56	53	59	58	59	58
Bronchitis	56	49	58	53	58	53
Angeles	51	33	53	53	53	53
Influenza	49	36	53	53	53	53
Gonorrhea	33	34	34	34	34	34
Syphilis	24	27	27	27	27	27
Consumption	23	23	23	23	23	23
Inflammation of kidney	20	18	18	18	18	18
Diarrhea	19	13	13	13	13	13
Cancer	19	23	23	23	23	23
Typhoid fever	12	17	17	17	17	17
Phomalarial	3	6	6	6	6	6
Smallpox	13	14	14	14	14	14
Scarlet fever	12	10	10	10	10	10
Pleuritis	12	16	16	16	16	16
Pneumonia	10	11	11	11	11	11
Inflammation of bowels	9	6	6	6	6	6
Intermittent fever	9	8	8	8	8	8
Erysipelas	8	6	6	6	6	6
Diphtheria	6	6	6	6	6	6
Measles	5	5	5	5	5	5
Dysentery	4	6	6	6	6	6
Whooping cough	3	2	2	2	2	2
Remittent fever	3	2	2	2	2	2
Inflammation of brain	2	2	2	2	2	2
Cholera morbus	1	3	3	3	3	3
Puerperal fever	1	3	3	3	3	3
Meningitis	0.7	0.3	0.3	0.3	0.3	0.3
Cholera infantum	0.7	0.3	0.3	0.3	0.3	0.3
Membranous croup	0.4	0.3	0.3	0.3	0.3	0.3

At the State Capitol for the month of December, 1904, compared with the average for December in the ten years, 1894-1903, tri-daily observations show the prevailing direction of the wind to have been the same (southwest), the velocity .3 of a mile per hour greater, the average temperature 4.41 degrees lower, the average daily range of temperature 2.1 degrees greater, the average daily range of atmospheric pressure .027 of an inch greater, the precipitation .77 of an inch less, the absolute humidity less, the relative humidity more, the day and night ozone much less, and the depth of water in the observation well 2 inches less. For the month of December, 1904, compared with the average for December in the ten years, 1894-1903, smallpox, dysentery, and in-

flammation of brain were more than usually prevalent; and pleuritis, pneumonia, intermittent fever, erysipelas, diphtheria, whooping cough, remittent fever, cholera morbus, puerperal fever, and meningitis were less than usually prevalent. In every month of 1904, six of the diseases which were less prevalent than usual in December—pneumonia, intermittent fever, erysipelas, whooping cough, remittent fever, and cholera morbus—caused considerably less sickness than the average of corresponding months in preceding years. Also, excepting July and August, this was true of pleuritis. Ten diseases caused less sickness in December, 1904, than the average for the ten preceding Decembers.

THE MOST DANGEROUS COMMUNICABLE DISEASES.

Including reports by regular observers and others, meningitis was reported present in Michigan during the month of December, 1904, at 5 places; whooping cough, at 19 places; measles, at 51 places; pneumonia, at 82 places; diphtheria, at 91 places; smallpox, at 101 places; typhoid fever, at 105 places; scarlet fever, at 126 places; and consumption, at 241 places. Reports from all sources show meningitis reported present at 1 place less; whooping cough, at 1 place more; measles, at 16 places more; pneumonia, at 23 places more; diphtheria, at 4 places more; smallpox, at 2 places more; typhoid fever, at 56 places less; scarlet fever, at 21 places more; and consumption, at 6 places less, in the month of December, 1904, when compared with the preceding month. Henry B. Baker, secretary.

The National Association for the Study and Prevention of Tuberculosis.—The first annual meeting of this national association will be held in Washington, D. C., at the New Willard Hotel on Thursday and Friday, May 18 and 19, 1905. There will be general sessions, and division of the work into the following three sections:

1. *Sociological:* Chairman, Mr. Homer Folks; secretary, Miss Lillian Brandt, United Charities Building, 105 East Twenty-second Street, New York. Executive committee, Dr. H. M. Bracken, of St. Paul; Dr. J. W. Brannan, of New York; Mr. E. P. Bicknell, of Chicago; Mr. Ed. T. Devine, of New York; Mr. Christopher Easton, of Newport; Professor Irving Fisher, of New Haven; Dr. John S. Fulton, of Baltimore; Mr. F. L. Hoffman, of Newark; Dr. J. N. Hurty, of Indianapolis; Dr. S. A. Knopf, of New York; Dr. Ernest Wende, of Buffalo; Mr. A. M. Wilson, of Boston.

2. *Pathological and Bacteriological:* Chairman, Dr. Mazyck P. Ravenel; secretary, Dr. D. J. McCarthy, Phipps Institute, Philadelphia. Executive committee, Dr. Ed. R. Baldwin, of Saranac Lake; Dr. William T. Councilman, of Boston; Dr. William T. Howard, Jr., of Cleveland; Dr. Hugh M. Kinghorn, of Saranac Lake; Dr. William G. MacCallum, of Baltimore; Dr. Roswell Park, of Buffalo; Dr. William H. Welch, of Baltimore.

3. *Clinical and Climatological:* Chairman, Dr. Norman Bridge; secretary, Dr. S. G. Bonney, Stedman Building, Denver, Colo. Executive committee, Dr. Robert H. Babcock, of Chicago; Dr. Frank Billings, of Chicago; Dr. Vincent Y. Bowditch, of Boston; Dr. Lawrance Brown, of Saranac Lake; Dr. J. P. C. Foster, of New Haven; Dr. Charles L. Greene, of St. Paul; Dr. Ed. G. Janeway, of New York; Dr. H. M. King, of Liberty, N. Y.; Dr. Arnold C. Klebs, of Chicago; Dr. H. R. M. Landis, of Philadelphia; Dr. Charles L. Minor, of Asheville; Dr. J. H. M. Minor, of Philadelphia; Dr. Ed. O. Otis, of Boston; Dr. William B. Stanton, of Philadelphia; Dr. A. Stengel, of Philadelphia; Dr. Joseph Walsh, of Philadelphia; Dr. James C. Wilson, of Philadelphia.

Pith of Current Literature.

PRESSE MEDICALE.

November 19, 1904.

Lecture at the Beginning of the Course on Experimental and Comparative Pathology, By ROGER.

History of Pathology.—Roger reviewed the history of experimental and comparative pathology with special laudation of Rayer, the first occupant of the chair instituted in 1862 in the Faculty of Medicine of Paris. He also pointed out the progress that has been made, the difficulties which have to be overcome, the sources whence the experimenter draws his inspiration, and finally the causes of the errors into which he is so easily led.

November 23, 1904.

Variations in Virulence, and Urinary Surgery, By GUYON.

Intervention in Urinary Surgery.—Guyon considers the important factors in increasing the toxic action of microbes to be the retention of normal secretion in an organ and an increase in the tension of its walls, modified in individual cases by the variations in the power of resistance. In urinary surgery intervention should be avoided when possible at the time when the increase of virulence renders the action dangerous. Intervention between attacks is one of the best guarantees of success. The only exceptions to this rule are when large and free incisions must be quickly made on account of infiltration of urine, urinary abscess, abscess of the prostate, of the kidney, in cases of septic retention, internal ureterotomy, and infection of the bladder, all of which operations are advantageously performed during the height of the inflammation.

November 26, 1904.

Medical Fees in Accident Cases, By FORGUE and JEANBRAU.

Fees in Accident Cases.—Forgue and Jeanbrau consider first, the fees for certificates, second, fees for attendance and operations, third what the physician may do should the patient refuse to pay the bill, fourth, the fee of the medicolegal expert. A valuable paper, but of less interest here because adjusted to French conditions, customs, and laws.

SEMAINE MEDICALE.

November 30, 1904.

Arterial Tension in Acute and Chronic Lead Poisoning, By VAQUEZ.

Arterial Tension in Lead Poisoning.—Vaquez considers that the characteristic feature of the hypertension of the arteries in lead poisoning is the rapidity and the intensity of its variations. A persistent hypertension is apt to indicate cerebral complications, either partial or general in character.

LYON MEDICAL

November 13, 1904.

Artificially Induced Labor Before or at Term, By VINCENT.

Induced Labor Before or at Term.—Vincent considers that labor may be legitimately induced at term to avoid dystocia due to a disproportion between the size of the fetus and the pelvic canal, and that it is not illegitimate to bring on labor at a certain hour, the same as a surgical operation, at

the end of the term, especially when the size of the fetus is such as to give rise to a fear of serious dystocia. He describes the various ways of inducing labor and expresses his preference for Tarnier's metallic dilator.

November 20, 1904.

A Very Simple Means of Regulating the Temperature in Infancy, By THEVENET and MOREAU.

Regulation of the Temperature in Infancy.—Thevenet and Moreau thought to place the fever patient in an incubator made of earthenware with a glass cover. In the lower part of the apparatus, ordinarily used for boiling water, pieces of ice are introduced and replaced as they melt away, but the question of ventilation proved insuperable for them, so they modified their method to the application of a cold coil to the abdomen. With this fever is reduced and nervous symptoms relieved.

November 27, 1904.

1. Resection of the Pylorus in Cancer of the Stomach According to Recent German Statistics, By LERICHE.

2. Fracture of the Base of the Skull, with Signs of Commotion and Contusion of the Brain. Relief of Symptoms by Lumbar Puncture, By LATARJET.

1. **Resection of the Pylorus in Cancer of the Stomach.**—Leriche, after a mention of the discredit into which pylorotomy, originally a French operation, has fallen, and a consideration of the great number of tumors which are found at autopsy to have been anatomically operable at the time of death, points out the great mortality attending the operation and in comparing it with gastroenterostomy says the one is grave, inefficacious, and rarely indicated, while the other is ordinarily easy and always gives relief.

2. **Fracture of Base. Lumbar Puncture.**—Latarjet, in the case reported, found the symptoms to be exceedingly grave and there was evidently fracture of the base. After removal of 20 c.c. of cerebrospinal fluid, there was an immediate improvement. In quarter of an hour there was less headache, the respiration was becoming regular, and two hours later the patient was eating with a good appetite.

RIFORMA MEDICA.

November 30, 1904.

1. Our Results with Opoththerapy in Syphilis, By A. RISSO and A. CIPOLLINA.
2. The Value and Technics of the Method of Ficker-Asakawa with "Typhusdiagnosticum," By L. BORELLI.
3. A Rare Case of Congenital Diaphragmatic Hernia, By ACHILLE ALBANESE.

1. **Serum Therapy in Syphilis.**—Risso and Cipollina give the results of their experiences with serum obtained from animals into which syphilitic material had been injected as immunizants. Their results, they claim, were much better than those of the other authors who preceded them in the same line of investigation. They injected subcutaneously in dogs considerable doses of the blood of syphilitics who were in the fully developed secondary stage of the disease. The injections were repeated three or four times, at intervals of about five days, and a week after the last injection the animals were bled. The whole blood was injected instead

of the serum, because it was thought that the blood corpuscles and other solid elements of the blood probably contain the contagious elements which it was desired to inject. Fourteen patients in the secondary stage of syphilis and two in the tertiary stage were treated with this serum. Of nine syphilitics in the full development of the secondary period, none of whom had had any other treatment, not one showed himself refractory to the serum, and in all of them the effects were far more prompt than those of the mercurial treatment in removing the eruptions, mucous patches, etc. In two patients the result was doubtful at the time of writing, but in these the treatment had been irregular and incomplete. The unpleasant effects of this serum were not any more pronounced than those produced by other serums. There were patients who bore doses of five c.c. each injected daily, without trouble, while others seemed less resistant and developed slight rashes, or sensitive spots. In such cases it was necessary to diminish the dose or else give the injections on alternate days. The authors conclude from their results that the serum which they prepared has a specific action in syphilis, but they do not deny that possibly it is only a stimulant to the resisting powers of the organism just as mercury is said to be (Tarnowsky). The authors do not agree with those observers who state that no specific serum for syphilis can be produced by injections into animals, for the reason that animals are not susceptible to syphilitic infection. It has not been conclusively proved that the lower animals are immune against syphilis, and hence are refractory, for example, to tetanus, but if tetanus bacilli and toxins are injected into them, they yield an antitetanic serum.

2. Ficker's Reaction in Typhoid.—Borelli concludes an investigation as to the value of Ficker's method of diagnosis in typhoid fever, by stating that this new method is fully as accurate and trustworthy as the Gruber-Widal reaction, and that therefore is able to serve as a substitute. When a very rapid reaction is desired, the freezing method of Asakawa may be employed. With Ficker's method one cannot only use the serum, but the whole blood which can be dried either on cardboard or on a glass slide. In using Asakawa's macroscopical method the dried blood may be used on paper, but for the microscopical examination, either the fresh or the dried blood may be used on a slide. The amount of blood needed for any of these tests is not larger than that required for the Widal test.

December 7, 1904.

1. A Reaction Employed to Demonstrate an Excess of Hydrochloric Acid in the Gastric Juice,
By A. CIPOLLINO.
2. The Influence of Soluble Ferments on the Digestibility of Cow's Milk,
By VINCENZO TRISCHITTA.
3. On a New Method of Selective Staining for Spores,
By G. SCAGLIOSI.
4. Perithelioma of the Thigh,
By FERRUCCIO BINDI.
5. Arthropathies and Cardiopathies,
By FRANCESCO SARCINELLI.

1. Reaction for Hydrochloric Acid.—The solutions required for the new test described by Cipollino are: Aniline water; a titrated solution

of sodium hypochlorite; and a solution of hydrochloric acid containing five parts of the acid to a thousand of water. One half c.c. of aniline water is poured into a test tube by means of a graduated pipette. Two c.c. of gastric juice (filtered) are added, and into this mixture are poured four or five drops of the solution of sodium hypochlorite. If the mixture assumes a yellow color, hyperacidity may at once be excluded. If, on the other hand, the mixture turns a violet color, the test should be repeated, using two parts of gastric juice diluted with one part of distilled water. If the violet color still appears then there is hyperacidity, in other words, the acidity is greater than two parts per thousand—the maximum in normal gastric juice. Some authors maintain that three parts per thousand is the normal maximum. If this opinion is held, the test may be performed with equal parts of distilled water and gastric juice. If the pale violet color persists, there is certainly hyperacidity. A dark violet color appears if there is hypacidity. The test depends on the fact that when a solution of sodium hypochlorite is mixed with some aniline water, an intense violet color results. If a solution of HCl over two tenths per cent. in strength is added, the mixture will turn a pale violet. If the solution of HCl is weaker, it will turn a red and then a yellow color, and if the HCl solution is weaker than $\frac{1}{4}$:1000, the violet color will be darker.

2. Ferments and the Digestibility of Cow's Milk.—Trischitta concludes from his experiments that trypsin is the most important ferment in the digestion of cow's milk. A dog fed on milk to which trypsin had been added increased in weight by 600 grammes within eight days. A control dog increased only by 350 with milk alone. Next in importance in the digestion of milk is pepsin, then emulsin. The author concludes that these ferments aid greatly in the digestion of milk and may, therefore, be added with profit to sterilized milk in order to render it more digestible. He suggests that the experiments which he carried on in dogs be repeated in a modified manner in children and infants. Sterilization of milk is necessary as long as we cannot give an infant milk as soon as it has been taken from the cow, and as long as we are not sure of the health of the cow. The addition of a mixture of pepsin, trypsin, and emulsin will obviate the inconveniences and disadvantages of sterilized milk.

3. Stain for Spores.—Scagliosi recommends the following method of staining spores of bacteria. The bacterial material is first fixed in van Gehuchten's or in Hermann's fluids. The author claims to be the first to apply cellular fixatives to the bacterial cell in cultures. He advises that the fixative liquids be poured over the bacterial colonies or smears in agar cultures, etc., and that the cultures so treated be allowed to remain in the thermostat for a sufficient length of time. The method which he proposes has the great advantage of fixing the bacterial bodies in the most favorable conditions, avoiding the disfiguring influences of heat, as ordinarily used. With von Gehuchten's fluid the fixation is accomplished after half an hour's contact; with Hermann's fluid after from ten to fifteen minutes. The material thus fixed is spread on slides

and the alcohol of the fixative is allowed to evaporate in the air at 37° C. The slides are then stained in Ziehl's fuchsin solution, washed in water, with or without the addition of sulphuric acid, and contrast stained in methylene blue solution. They are then dried in the air and mounted in balsam. The spores stain very distinctly with this method. The stain is of value especially for morphological studies in bacteria.

5. Arthropathy and Heart Disease.—Sarcinelli concludes as follows, on the basis of his observations as to the connection of heart disease with affections of the joints. Cardiac complications occur rarely as the result of acute articular rheumatism and the laws enunciated by Bouillaud on this subject are not in correspondence with observed facts. There is a connection between the form of joint affection and the type of heart disease which follows, the opinions of numerous authors to the contrary notwithstanding. The subacute and chronic forms of rheumatic arthritis are often complicated by cardiac affections, but not the acute forms. There are two types of cardiopathy which may occur with rheumatism. One type occurs with the subacute and the chronic form, and the other type with the acute form. While in the cases accompanying the acute forms, the subjective symptoms are not marked, the physical signs are pronounced. On the other hand, in the type accompanying the chronic forms, the subjective and external signs of cardiac insufficiency are prominent.

ROUSSKY VRATCH.

December 4, 1904.

1. On the Physiology of the Intestines,
By N. D. STARZHECO.
2. Repeated Extrauterine Pregnancies, By I. A. VOFF.
3. The Cholera in Baku,
By I. M. LEPLINSKI and I. S. ELIASHVILI.
4. Empyema of the Pleural Cavity, and Its Operative
Treatment (Concluded), By S. S. GRIGOLAFF.
5. Contribution to Our Knowledge of Tetany,
By E. E. VOSS.

1. Functions of the Cæcum, the Small Intestine, and the Colon.—Starzhesco's investigations on dogs with fistulæ at the end of the small, and the beginning of the large intestines were intended to elucidate the functions of the small and the large guts as related to each other and to bring out the physiological properties of the cæcum and the valve of Bauhin. His researches on the intestinal juice from the cæcum showed that this part of the intestinal tract does not secrete any special fluid, unless there is a special stimulus. When such a stimulus is present, however, the secretion of the cæcum begins immediately, and does not depend on the amount or the variety of the food introduced. The juice of the cæcum is capable of digesting independently proteid substances, to convert peptones into crystalloid substances, to saccharify starch, and to invert glucose and maltose. The cæcum, in contrast with the juice of the small intestine, cannot turn protrypsin into true trypsin, and does not contain any true kinase. Yet the juice of the cæcum does improve the action

of the pancreatic juices, especially that of amylase and lipase. Another interesting series of facts developed in this investigation was the function of Bauhin's valve, the purpose of which is to keep back the contents of the small intestine as long as is necessary for the digestive process to be taken up by the colon. While the mucous membrane of the small intestine is exceedingly sensitive, that of the large gut is not at all so. The great bulk of the digestive processes takes place above the ileocæcal valve and by the time this part of the tract is reached most of the food has been absorbed. In fact, only 7 per cent. of the proteids, 2 per cent. of the carbohydrates and from 5 to 6 per cent. of the fats are passed along into the cæcum. Some absorption does go on in the large intestine, however, because the amounts of these classes of substances in the fæces of a normal animal are still smaller. The colon is the least important part of the tract as regards digestion. When the small intestine is diseased, however, a larger amount of undigested material passes into the colon and thus is thrown upon the latter for the purposes of digestion.

2. Repeated Extrauterine Pregnancies.—Voff reports three cases in each of which extrauterine pregnancy had occurred twice. In two cases the first operation for extrauterine gestation had been performed elsewhere, four and ten years respectively, before the second pregnancy. In one case the first operation was performed by the author two years before the second. In view of the rarity of such cases, and in view of the importance of studying them as to their relation to the ætiology of extrauterine pregnancy in general, the author pleads for a more detailed description of all cases which occur hereafter, together with a careful microscopical examination of the removed tubes wherever possible. The interesting feature of the case which was observed during both pregnancies by the author himself, was that at the first operation the right annexa were removed, while the left tube and ovary were found to be perfectly normal. It was in this tube that the second pregnancy was found to have taken place.

3. Cholera in the City of Baku.—Leplinski and Eliashvili in this preliminary communication report the results of their bacteriological examinations of the city water of Baku, where the cholera raged during the month of September of the year just closed. Baku, being situated at the borders of the Caspian Sea, derives its water supply from wells, which give a bitter-salty water that is drunk mostly by the natives, and from the sea itself, the water of which is distilled and drunk chiefly by the Europeans. Samples of water were taken from the sea, from the wells and from baths in the town. During this epidemic the first cholera vibrios were found by the authors in the water of the swimming tanks of the Persian baths, on September 12th. Later these germs were found in samples from wells, of which two hundred have been examined to date. It was noticed that at first the only people to be infected were the Mahometans of the Tcherembekent district, and among these almost exclusively the women. After the vibrios had been discovered in the baths in this district, the morbidity

among the inhabitants of that part of the town was reduced at once to the minimum, inasmuch as the baths were closed by the authorities. These baths undoubtedly were the first and most important sources of the contagion. The baths frequented by Mussulmans only to which the authors refer were peculiarly constructed. They were built partly underground and consisted of a round semidark dressing room, and a bathroom containing a tank lined with stones and filled with water to the height of about five feet, known as the common tank. This tank was cleaned out once a month, or even less frequently, for when the water was drawn off there was liquid mud up to one's knee. In this bathing tank the women of the Mussulmans of the town bathed on a certain day of the week, and incidentally brought the laundry of their families to be washed in the same tank. They would spend all day in the baths, drinking tea, etc. The conclusions of the author emphasize the necessity of prohibiting the use of public baths during epidemics of cholera, and the propriety of a sanitary inspection of such institutions.

4. Operations for Empyema.—According to Grigolaff the place of election for empyema operations is at the eighth rib, up to the scapular line. He does not favor the use of antiseptics in washing the pleural cavity. Mechanical washing with one per cent. solutions of sodium chloride, or with physiologic salt solution may be used only in cases in which the pus is decomposed. One drain is sufficient in all cases, and it may be made shorter and smaller as the case progresses. Tamponage is only to be used when the cavity of the pleura has already healed.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

January 7, 1905.

1. History of the Clinical Recognition of Gastric Ulcer,
By JOHN C. HEMMETER.
2. Blindness and Oculomotor Palsies from Injuries Not
Involving the Optic or Oculomotor Nerves,
By ALVIN A. HUBBELL.
3. Contraction of the Visual Field; a Symptom of Anæsthesia of the Retina in Children,
By L. WEBSTER FOX.
4. An Exact and Secure Tucking Operation for Advancing an Ocular Muscle,
By FRANK C. TODD.
5. The Passage of Different Foodstuffs from the Stomach,
By WALTER B. CANNON.
6. The Diagnosis of Enlarged Bronchial Lymph Nodes,
By ALFRED FRIEDLANDER.
7. The Importance of an Early Aural Examination in Acute Diseases of Children,
By JAMES F. MCKERNON.
8. Some Physical Signs in Infants and Children Not Sufficiently Emphasized,
By SAMUEL McC. HAMILL and THEODORE LE BOUTILLIER.
9. Congenital Dislocation of the Hip. An Argument Concerning the Method of Its Treatment,
By HENRY M. SHERMAN.
10. The Trend of Modern Prescription Writing,
By M. CLAYTON THRUSH.

2. Blindness and Oculomotor Palsies.—Hubbell attempts to determine the possibility of blind-

ness and oculomotor palsies in cases in which there has been traumatism which, however, has not involved directly or indirectly any of the eye nerves. That is to say, can blindness and oculomotor palsies be due to reflex influences? The author believes that they can. Cases are quoted from the literature to uphold this view. In addition ten personal cases are recorded, six of paralysis of the extraocular muscles in which there was no evidence of injury either to the muscles or to their nerve supply, and four of unilateral blindness. In these last four cases it is perhaps not possible to assert positively that the optic nerve was not injured. The author does not think that it was.

4. A New Tucking Operation.—Todd's method is as follows: A flap of conjunctiva is dissected up and turned back, exposing the tendon to be tucked. A special instrument is now required. This (a tendon tucker) consists essentially of two arms which cross each other, so as to form an X, the lower legs of which are joined by a long loop. By turning a screw in the loop end the distal ends are made to approach each other, cross each other and finally retreat from each other, to an approximately parallel position. One arm of the closed tucker is placed below and one above the tendon to be shortened. As arms are made parallel, the tuck is made. This is secured by two sutures at right angles to the tendon. Two other sutures secure the centre of the tuck in the tendon to the corners of the conjunctival flap. This completes the operation. The article is illustrated. The author claims the following advantages for his operation: (1) Exactness. Perfect adjustment of the eye may be secured at the time of operation when tying the silk sutures after the tuck has been taken. (In nearly all advancement operations the operator is obliged to estimate the amount of the effect desired and does not know until his operation has been completed the exact amount of effect that has been produced.) (2) Security. When the operation is completed the stitches cannot slip and the tendon will remain where it has been placed. (3) Ease. The operation is very easy of performance, made so by the use of the instrument. (4) Flexibility. The smallest or the greatest amount of deviation may be produced. (5) Strabismus of high degree. The greatest degree of effect can be produced when accompanied by a tenotomy of the opposing muscle, and thus a strabismus of the highest degree can be corrected by operation on one eye alone if desired.

6 and 7. See this *Journal*, Vol. LXXX, page 330.

8. See this *Journal*, Vol. LXXX, page 331.

9. Congenital Dislocation of the Hip.—Sherman gives his reasons for not liking the method advocated by Lorenz for replacing congenitally dislocated hips. The method is not "bloodless," it is not safe, it is not efficient, except in a very small percentage of cases (ten to twenty per cent.). Worse than all, if unsuccessful, it is

liable to so injure the capsule that a future arthrotomy cannot be performed. The author advocates the following method: (1) Arthrotomy for the purpose of overcoming the most serious obstacle to manual reduction. (2) Manual reduction. (3) Plaster dressing for about nine months. The author briefly analyses twenty-eight cases which he has treated by arthrotomy.

BOSTON MEDICAL AND SURGICAL JOURNAL.

January 5, 1905.

1. A Consideration of Autointoxication and Autoinfection as Cause of Various Mental Disorders (*To be continued*), By L. VERNON BRIGGS.
2. The Geographical Distribution of Tuberculosis in Boston in 1901-3 as Compared with the Distribution in 1885-90, By ARTHUR K. STONE and ALEXANDER M. WILSON.
3. Improved Technics for Finney's Gastroduodenostomy, By ALFRED H. GOULD.
4. Cardiac Collapse During Examination of a Postpharyngeal Abscess; Incision; Circulation Reestablished and Maintained for Four Hours by Massage of the Heart; Death, By DAVID CHEEVER.

3. Improved Finney Gastroduodenostomy.—Gould's paper is the second of a series of four dealing with improved surgical technics. The proposed improvements are three: (1) The manner of placing the clamps. (2) The method of opening the stomach and duodenum and the excision of a piece of the stomach's mucous membrane. (3) The omission of guide sutures. Method.—Two long clamps, protected with rubber, are used. A fold of the anterior wall of the stomach is picked up 3 to 4 inches long, parallel to and about $\frac{1}{2}$ inch from the greater curvature. The ends of the clamp are not freed, but are pushed up tightly until the inner jaw rests against the pyloric sphincter, about $\frac{1}{4}$ to $\frac{1}{2}$ inch below the free edge of the fold, where they are made fast. The duodenal clamp encloses a similar fold, as it goes obliquely across the bowel from the free edge to the pylorus and is pushed up until its inner jaw touches that of the stomach clamp, where it is fastened. The handles of the clamps are next brought together. The adjoining sides of the duodenum and stomach are now sutured. The stomach is incised down to the mucosa. The duodenum is next incised into its lumen and, if necessary, the mucous membrane is trimmed. The bulging mucous membrane of the stomach is now excised. A continuous through and through stitch unites the adjacent edges of the openings in the gut and stomach. This stitch is continued round to within one inch of the point of beginning. The clamps are removed and union of the gut to the stomach completed. A layer of seromuscular stitches buries the first line of sutures. The article is illustrated.

4. Massage of the Heart.—Cheever in the title of his paper gives the principal points relating to his case. The heart was massaged through the ribs by means of rhythmic compressions and not, as has been advised by some, through an incision. The author believes that he was able to

reestablish by this means an already arrested circulation and maintain it, as well as a fair aeration of the blood, for four hours. The general lesson to be drawn is that in cases of extreme exhaustion due to postpharyngeal abscess, it is well to perform a preliminary tracheotomy.

AMERICAN MEDICINE.

January 7, 1905.

1. The Behavior of Native Japanese Cattle in Regard to Tuberculosis (Perlsucht), By S. KITASATO.
2. Is Mortality Necessarily Higher in Tropical Than in Temperate Climates? By COLONEL V. HAVARD.
3. The Treatment of Cancer of the Cervix Uteri in Advanced Stages, By J. WESLEY BOVÉE.
4. An Experimental Study of Lactic Acid Formation, with Special Reference to the Stomach, By E. PALIER.
5. Some Observations Upon Astigmatism, By L. L. DOANE.
6. Fatal Case of Cerebellar Abscess, By JOHN H. ALLEN.
7. American Medicine, By E. J. KEMPF.

1. The Transmission of Tuberculosis.—Kitasato's paper shows that, in Japan at least, the chief if not only source from which tuberculosis is spread is man. The native Japanese cattle are practically free from the disease, while human tuberculosis, including the intestinal variety, has been known since the beginning of medical history. The author presents the following formal conclusions: (1) Human tuberculosis is as frequent in Japan as in the civilized countries of Europe and America. (2) Primary intestinal tuberculosis is relatively common in adults and children, although cow's milk plays no rôle at all in the feeding of children. (3) There are large districts in Japan, where, in spite of the existence of human tuberculosis the cattle remain absolutely free from the disease. In these regions it is not customary to consume either meat or milk from bovines. (4) This is very important proof of the fact that under ordinary conditions human tuberculosis is not infectious for bovines, as the opportunities for infection certainly cannot be lacking. (5) Among Japanese in general very little cow's milk is used and especially is it employed but little for the dietary of children. (6) Under natural conditions the native animals show but very little susceptibility for perlsucht. If large doses of perlsucht bacilli are inoculated into them either intravenously or intraperitoneally, they become tuberculous to a certain degree; they do not seem to be at all susceptible to subcutaneous infection. (7) The imported and mixed race animals are very susceptible to perlsucht. (8) Human tuberculosis is not infectious for native and mixed race animals.

2. Mortality in the Tropics.—Havard concludes that, with care in his habits and diet, the northerner going to the tropics has, in the absence of epidemic, as good chances of health and longevity as in temperate climates, but must resign himself to the loss of more or less of his bodily and mental activity. He arrives at this conclusion after reviewing the recorded mortality of both civil and military populations quartered in the tropics. Most of the author's personal knowledge was acquired in Cuba and the Philippines.

3. **Cancer of the Cervix.**—Bové, after reviewing the chief points of interest connected with cancer of the cervix gives the following advice with regard to its treatment: (1) Severe surgical operations, involving appreciable mortality rates or a marked degree of additional suffering, should not be employed in the treatment of carcinoma of the cervix uteri, except in very early cases. (2) According to the reports of the exhaustive microscopical examinations in serial sections of the tissue surrounding the uterus in cancer of the cervix, we have no means of knowing before operation that eradication is certain in any given case of this disease, and hence such attempts must be reserved for the very earliest and most promising ones. (3) The galvanocautery offers the best prospects for prolonging life, relieving pain, and lessening discharges in all other cases.

4. **Lactic Acid Formation.**—Palier holds that the meaning of the presence of lactic acid in the stomach is not well understood, because the question has been studied from the clinical point of view merely. He has studied it from the laboratory side. That is, he has put various foodstuffs in test tubes and then subjected them to different conditions. From these experiments he has formulated the following laws: (1) Lactic acid develops in all organic substances containing carbohydrates, whether sugar or starch; and in some substances even while yet in solid form, such as bread and meat, for instance, at certain seasons which are especially favorable for bacterial development, some lactic acid exists already; and on dissolving such substances in water the lactic acid reaction can be soon detected. (2) Lactic acid formation is due in all cases to bacterial development, even the so called sarcolactic acid of meat. Furthermore, many kinds of bacteria can by their development bring about the formation of lactic acid in substances containing carbohydrates; but the bacteria usually vary in the different substances. (3) Lactic acid does not give the usual reaction with the usual tests when an inorganic acid is also present in sufficient strength. (4) The lactic acid development is hindered when there is an antiseptic present, such as HCl, for example, acting against those bacteria which bring about the lactic acid development; but the lactic acid that had been formed before HCl was added is not destroyed when the latter is added. It is only masked as far as the ordinary reactions are concerned and its further development arrested; but it can be separated by means known to chemistry. (5) HCl enters in combination with albuminoids, and after some time it does not give the usual reaction, though it was marked when it was first added; and then bacteria appear, and also lactic acid begins to form, the latter in substances containing carbohydrates. The practical clinical significance of the experiments can be stated thus, so far as the stomach is concerned: Whenever the total acidity is 40 per cent. or more after a test meal of a roll of bread and a glass of tea, and the HCl is insignificant or entirely negative, there is alimentary stasis of the previous day or days; for the total acidity of bread and water in a test tube is

only about 20 per cent. at the end of week. Furthermore, the organic acidity in the stomach contents with a deficiency of HCl is mostly due to lactic acid, as comparatively little of the fatty acids develops in such cases.

6. **Cerebellar Abscess.**—Allen reports a case of cerebellar abscess, in which a correct diagnosis was not made, and which terminated fatally. The symptoms from which the patient suffered aroused the suspicion of abscess, but they were not sufficiently definite to justify radical intervention.

1. Disturbances of Digestion in Infants Resulting from the Use of Too High Fat Percentages,
By L. EMMETT HOLT.
2. Medical Quacks, Their Methods and Dangers,
By CHAMPS S. ANDREWS.
3. Anal Fissure,
By WILLIAM M. BEACH.
4. The Physics and Chemistry of Drug Action,
By EDWARD C. HILL.
5. Some Recent Developments in Clinical Pathology,
By FREDERIC E. SONDERN.

1. **Too High Fat Percentages.**—Holt asserts that many physicians do not appreciate that a too high fat percentage is capable of doing a bottle fed baby much harm. Excessively high fat percentages result chiefly from two causes: (1) From the desire of the physician to overcome constipation. (2) From the belief that the richer the dairy milk the better. That is to say, rich Jersey milk, which contains about 5.5 per cent. fat, is used with formulae calculated for ordinary milk which averages 4 per cent. fat. Personally the author has never seen the necessity for increasing the fat of bottle milk above 4 per cent. Five illustrative cases are reported to show how much damage may be caused by high fat content.

2. **Medical Quacks.**—Andrews draws upon his personal experience, as counsel of the Medical Society of the County of New York, for specific illustrations of the various, more or less artistic, ways of swindling the public which are in vogue among the medical fakirs of the metropolis.

3. **Anal Fissure.**—Beach devotes some space to the aetiology and symptomatology of anal fissure. The following treatment is advised: In the early stages laxative and topical treatment will usually suffice. If the stage of a fresh wound is passed then surgical treatment alone will be of avail. Stretching the sphincter is not required. Cutting a few fibres of muscle directly back of and beneath the ulcer will answer the same purpose. The lesion itself should be cut through, the indurated margins trimmed, and the base curetted. All this can be done under local anaesthesia. The after treatment consists in keeping the edges of the ulcer apart and in applying astringents.

4. **Drug Action.**—Hill's paper cannot be condensed. He attempts to give the physical and chemical explanation for the action of the various classes of drugs.

5. A Note on the Treatment of Thrombosis of the Superficial Veins of the Lower Extremities, By C. M. MOULLIN.
6. The Anthropometric Investigation of Hospital Patients, By F. C. SHRUBSALL.

1. **Stone in the Kidney.**—Robinson, in a clinical lecture on renal calculus, tells us that whatever the remote cause may be (food, water, etc.) the immediate cause is an error in metabolism leading to the excessive production and excretion of uric acid, calcium oxalate, or phosphates. The cohesion of these crystals in a matrix of colloid material forms the calculus. The symptoms are variable and indefinite. Three signs stand out: pain, attacks of renal colic, and hæmaturia, but the only constant one is pain. When this is the only symptom the diagnosis is difficult, as it may be simulated by affections of the stomach, colon, or gall bladder. Any stone free to move about in the pelvis or calices is likely to be the most painful, while a stone fixed in both pelvis and calices may exist with little (perhaps dull aching) or no pain. Stones fixed in the parenchyma may give little or no pain. An oxalate stone, which is usually rough, is supposed to cause the most pain, then a phosphatic, and last a smooth uric acid stone. The pain may be a dull ache, behind and under the last rib, or a sharp pain radiating downward into the thigh or the penis. It is only a one sided pain that is any use in diagnosis. The most typical attacks of renal colic are due to a stone travelling down the ureter. Much the same may be seen where a blood clot is passing down the ureter. Hæmaturia is far less common than is generally believed. The blood is usually mixed with the urine without clots. If the bleeding is considerable, casts of the pelvis or ureter may be found. Hæmaturia of whatever degree is not constant; its appearance may be related to exercise or jolting, and it may cease with rest. The use of the x rays as a means of diagnosis is of very doubtful value. Oxalate of calcium should give the best shadow, and uric acid the least. A thick loin, restlessness, or the presence of blood, all prevent good definition. The best method of exposing the kidney is through a lumbar incision behind the peritonæum. The usual incision begins just below the twelfth rib at its junction with the outer border of the erector spinae, and extends forwards for about four or five inches in a line directed towards the anterior superior spine. The incision into the kidney itself should be a vertical one about the convex border, passing well into the pelvis so that the finger can be easily introduced to make a thorough examination. Any stone found should be removed with forceps or scoop. Where the cortex is thinned and riddled with calculous particles, removal of the kidney must be done.

2. **Local Analgesia.**—Barker describes the use of β -eucaine as a local anæsthetic, and finds it difficult to understand why cocaine is still employed. Within one day he has by this method performed the following operations: Amputation through the knee joint for diabetic gangrene; abdominal section and opening of the stomach and jejunum in a case of severe hæmorrhage; removal of a thyroid cyst; Bassini's radical cure of inguinal hernia; and removal of a silver wire from round the patella. The author has never seen any depressing effects follow the use of eucaine. In reaching the nerves of a part hollow needles of varying length are thrust into their immediate neighborhood or across their course at some distance from the area of operation. Abdominal organs are *per se* insensitive to pain. The solution used is as follows: Distilled water, 100 grammes, β -eucaine, 0.2 gramme; sodium chloride, 0.8 gramme; and one in one thousand adrenalin solution 10 drops. All this fluid can be used in an ordinary case if necessary and is quite sufficient for most. Where possible the circulation of the part is to be retarded by ligature or by the application of cold, thus maintaining, and even intensifying the action of the analgetic. The adrenalin retards the blood flow, and the eucaine only reaches the higher nerve centres very slowly, if at all. The solution is isotonic and indifferent to the tissues. As stated above the duration of the insensibility is secured by the admixture of the adrenalin. Without it sensation is only abolished for fifteen minutes, with it for three or four hours, or as long as the anæmia lasts. The insensibility does not become fully developed until thirty minutes after the injection. After this it deepens for a couple of hours. The fluid should not be used too cold or too hot. All dragging upon the parts is to be avoided, lest structures be pulled upon which lie beyond the area of infiltration. This is especially true in abdominal operations. As for general anaesthesia so also for the local preparation of the patient beforehand is most important. But a preliminary fast is not desirable. It should never be suggested to the patients that they may have pain.

3. **Chloroform Anaesthesia.**—Waller's investigations show the following: 1. That ether is less powerful than chloroform, but also less dangerous: so that chloroform should not be used in minor surgical operations. 2. That there is a parallel action of anaesthetics upon nervous tissues and upon cardiac tissues. 3. That chloroform is not an uncertain reagent, but that it produces effects strictly proportional to the mass in which it acts. For purposes of anaesthesia it should be administered in dilution with air at a percentage of not below one per cent. and not above two per cent.

5. **Thrombosis of the Superficial Veins of the Leg.**—Moullin has abandoned the ordinary treatment of thrombosed superficial veins of the lower extremities by rest and lotions, and for some years has at the very earliest opportunity excised the whole thrombosed portion of the vein, with the most excellent results. The wound is sound in a week and the patient can get up cured and freed

from all the risks of embolism, deep thrombosis, or recurrence.

By J. R. MORISON.
9. Note on a Case of Acute Cerebral Abscess,
By A. L. WHITEHEAD.

2. Congenital Intestinal Atresia.—Clogg records two cases of that comparatively rare affection, congenital intestinal atresia. Both cases proved fatal. In 250,000 children the disease (excluding rectal cases) has been observed only nine times. The atresia may be found in the duodenum, the jejunum or the large intestine. The most frequent condition in the jejunum is complete obliteration of the lumen, the two ends being united by a band. Rarely the band may be absent, and the two ends separated for some distance. Atresia of the colon is very rare: the lumen of the intestine below the obstruction is very narrow and the bowel is empty. It seems quite conceivable that intestinal invagination may be a frequent cause of intestinal atresia. Anomalies in the vascular system, embolism, and thrombosis of the mesenteric vessels, and compression of the intestine by an artery are also given as causes: also foetal peritonitis, torsion of the intestine, ulceration, and errors of development. In the small intestine many cases can be traced to Meckel's diverticulum. Most, if not all, malformations in the duodenum are associated in some way with the development of the large glands in this region. Snaring of the intestines by the umbilical ring accounts for some cases of occlusion of the small intestine. The symptoms are vomiting, persistent and increasing in severity; abdominal distention; visible peristalsis; nothing practically is passed per rectum; the anus and rectum are well formed; rapid emaciation and exhaustion ensue, the disease running to a rapidly fatal issue. In general the higher the occlusion, the earlier the vomiting. The character of the vomitus and stools depends upon the position of the obstruction as regards the bile duct. The only possible hope for an infant born with intestinal occlusion is that afforded by surgery. Enterostomy is the course which has been most frequently practised, but it is nothing more than a palliative operation. Anastomosis is the ideal operation, but the shock which accompanies it often

proves fatal. If the obstruction is in the duodenum, and jaundice exists, operation is useless.

3. Intravenous Antitoxine Injection.—Biernacki and Muir report two series of grave cases of diphtheria treated by intravenous injections of antitoxine. In the first series of seven cases there were five deaths, and no evidence that the serum was more effective than when given subcutaneously. In the second series of thirty-eight cases, however, there were only three deaths. In attempting to estimate the beneficial effects of antitoxine given intravenously those cases must be discounted in which a marked improvement follows intubation or tracheotomy, since this may be due mainly, or entirely, to relief of the obstruction. Out of nine patients so operated on only one died. Nevertheless, the authors, even in the second series, could not say definitely of any individual patient that a better result was obtained than might have followed subcutaneous injection.

4. Smallpox Parasites.—De Korté thinks that he has found the parasites of smallpox, vaccinia, and varicella. Storing the lymph in capillary tubes, and keeping it for several months, he makes hanging drop preparations, in which the amoeba-like bodies can readily be found. He gives the protozoon the name of *Amœba variola vel vaccinia*. It is amoeboid, and has for the most part an oblate spheroidal shape, but large encysted forms are also found. It is about one twenty-five thousandth of an inch in diameter. It consists essentially of cytoplasm enclosed in a cell wall, with a rounded or ovoid nucleus. The cytoplasm contains numerous granules or spores. On the warm stage the amoeba constantly alters its contour. Variolous matter contains a large number of amoebæ but relatively few extracellular spores. Absolutely fresh material can be fixed in alcohol and ether, and stained with Löffler's methylene blue; the parasite takes up the stain irregularly, and the nucleus not at all. In human vaccine lymph it is probable that the height of the inflammatory process, the eighth or ninth day, is coincident with the presence of the maximum number of amoebæ. The author has also detected in varicella lymph bodies similar in general characters to those seen in variola and vaccinia.

5. Infantile Convulsions.—Moon states that a serious view should be taken of all convulsions occurring in infancy. In most of the cases the parents have a history of epilepsy or alcoholism, which are predisposing causes of epilepsy. Even repeated convulsions in a normal brain make that brain cease to be normal and create a distinct pathological basis for epilepsy.

6. Hæmoconia.—Love has found in the blood of patients suffering from typhus fever, measles, scarlet fever, smallpox, and syphilis, four varieties of hæmoconia or "blood dust." 1. Protoplasmic bodies containing a number of bright refractile points. These are fragments of ventrophile cells. 2. Small round highly refractile bodies, apparently motile. 3. Rodlike bodies, also motile. 4. Dumb-bell forms, also motile. The last three forms probably belong to the same class. The fact that they do not stain negatives the theory that they are derived from leucocytes.

Letters to the Editor.

DR. WILEY ON METHYL ALCOHOL.

WASHINGTON, D. C., January 4, 1905.

To the Editor,

Sir: By inadvertence in describing the test for methyl alcohol on page 1010 of the *New York Medical Journal* and *Philadelphia Medical Journal* of November 26, 1904, I mentioned phloroglucin as an alternative for resorcin. In point of fact resorcin alone is used with sulphuric acid and phloroglucin with sodium hydroxide. I beg, therefore, my readers to correct the description of the test by taking out the words "or phloroglucin" following "resorcin" in the two places on page 1010.

The test with phloroglucin is made as follows: The oxidation of the methyl alcohol is carried on as described on page 1010 of your issue of November 26, 1904. Acetaldehyde is removed by adding to the liquid remaining in the test tube 6 cubic centimetres of a 3 per cent. solution of hydrogen peroxide or an equivalent amount of hydrogen peroxide if in a different state of dilution. Mix the contents of the tube and filter into a porcelain dish. After three minutes add 2 cubic centimetres of a 10 per cent. solution of sodium thiosulphate. Next add 3 cubic centimetres of a phloroglucin solution obtained by dissolving 1 gramme of phloroglucin and 20 grammes of sodium hydroxide in water and making the volume to 100 cubic centimetres. A bright red coloration indicates the presence of methyl alcohol in the original sample. The intensity of the red color is in some degree proportionate to the quantity of methyl alcohol originally present. When carefully made 1 part of methyl alcohol in 20 parts of ethyl alcohol can be detected by this reaction.

H. W. WILEY.

Acute Myelocytic Anæmia.—Elder and Fowler, in the *Edinburgh Medical Journal*, for December, 1904, conclude their paper, which is mainly an analysis of seven cases of the above mentioned condition, as follows:

1. The course and clinical features of this condition are practically identical with those of the much more common acute lymphocytic leucæmia.
2. The anæmia is generally greater than in the ordinary chronic cases. One of the cases in the authors' series is of the variety described by Leube as leucanæmia on account of the extreme qualitative and quantitative alterations in the red cells. The authors agree with Hirschfeld, however, in regarding it as acute myelocytic leucæmia.
3. The leucocyte count is not always high, it may be little above normal, but it sometimes rises to a figure comparable to that which obtains in chronic cases.
4. Eosinophiles may be absent or few in number, the same being true even to a greater extent of mast cells. As in other cases of a typical leucæmia, many of the leucocytes are difficult to classify, and one frequently observes forms which are morphologically intermediate between large lymphocytes and myelocytes. Non-granular polynuclears are also to be observed. Normoblasts may be absent or plentiful, and megakaryoblasts are sometimes present.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, December 1, 1904.

The President, Dr. RICHARD C. NORRIS, in the chair.

Chorioepithelioma Malignum.—Dr. P. B. BLAND read a paper with this title, and reported the following case: The patient was thirty-one years of age. One maternal aunt died of cancer of the uterus. The patient herself had always enjoyed comparatively good health. She was married at eighteen and had had five labors. The first four were normal, the fifth occurred at the eighth month and was hastened or produced by sustaining a severe fall. Her symptoms began about four months after her last labor and six months before her admission into the hospital. These consisted in more or less vague and indefinite pains in the lower portion of the abdomen, of a dull, aching, boring character. Two months prior to her admission she suffered from a rather free serous and offensive discharge, which soon became tinged with blood. The bleeding progressively increased in intensity. On admission the patient was extremely pale and anæmic, and had lost considerable flesh. Examination revealed the uterus of twice its normal size. It was more or less soft in consistence, the cervix was large, and the os admitted the tip of the index finger. There was no palpable pathological alteration in the tissues outside of the uterus. The patient was prepared for operation, but before opening the abdomen the uterus was dilated and a nodular mass discovered in its interior. Some of this was removed and resembled so strikingly malignant disease that hysterectomy was decided upon and performed.

The uterus was possibly of two or two and a half times its normal size, and the enlargement was uniform. The uterine wall was thickened and showed changes found in subinvolution. Occupying the interior of the uterus, on its posterior wall and in the fundal region, a large, irregular nodular mass was found. This was of a greenish blood coagulum color and of rather tense consistence. The nodules varied in size from a pea to a man's thumb. The mass did not show any line of demarcation between itself and the uterus, but apparently infiltrated the uterine wall to the extent of three eighths of an inch. The ovarian vein of the right side was distended greatly by an organizing thrombus. A portion of this was protruding from the vessel after removal. Microscopical examination of sections of the nodules revealed the tumor to be a typical chorioepithelioma. The patient was living and well eight months after the operation, without any subjective manifestations of recurrence of the disease.

The writer reviewed the early history of chorioepithelioma, and believed from his observation and study that there should be no controversy as to the nomenclature of these tumors. He believed, with Marchand, that they developed, as was recognized in his case, from the epithelial

coverings of the chorionic villi, and, therefore, that chorioepithelioma malignum was an appropriate term. He thought, in discussing the pathology, that the line of invasion in chorioepithelioma was distinctively characteristic of the tumor, differing from carcinoma, in that it was soft, mushy, and sloughing. In carcinomatous tumors the line of invasion, as was well known, was hard, dense, and firm.

Dr. Bland spoke at some length of other neoplasms containing chorionic cells, and believed, with the late observers, that they should be classed with the teratomata and not considered as true chorioepithelioma; for it would be better, he thought, to adopt a nomenclature which would distinguish those closely connected with gestation and those arising independently of it. The author also discussed in detail the ætiology of these tumors, reviewing all the theories thus far advanced as to their causation. He strongly inclined to Ehrlich's side chain theory. The high type of malignancy exhibited by these tumors he believed to be due to the time of their occurrence or their association with the preceding pregnancy. He discussed in full the symptoms and diagnosis of the condition and the prognosis. The latter he believed was extremely grave. It was perhaps the most malignant of all tumors, occurring as it did during the full physiological activity of the patient, and with the physiological process of pregnancy, in an organ in which the blood vessels were greatly multiplied and enlarged and therefore in a state highly favorable for the transportation of malignant cells throughout the body. The outlook for the patient, however, could not positively be asserted to be either good or bad, in view of the fact that spontaneous healing had occurred in some, and that even in extensive cases of metastases after removal of the primary site of infection, patients had recovered.

Dr. BARTON COOKE HIRST said he had seen two cases of chorioepithelioma, one of which began immediately after labor and ended fatally in three months. The patient had at first refused operation, but later returned to the hospital soliciting it, when it was too late. The second case was a metastatic tumor in the brain following hydatidiform mole, from which the patient died about six months after the expulsion of the diseased ovum. There was nothing in the intrauterine examination to indicate malignancy. The most interesting question to the practical man Dr. Hirst considered to be that of diagnosis. He exhibited a drawing of a case seen last year. The woman had been bleeding off and on during pregnancy. She was delivered prematurely between the sixth and seventh months. Three or four days after delivery she had begun to bleed, and profuse hæmorrhage continued until his arrival, when the woman was in a desperate condition. The vagina was packed and the woman sent to the University Hospital. The following day Dr. Hirst called the attention of the class to the causes of hæmorrhage from the uterus after childbirth, and mentioned among the causes retention of some portion of the ovum and, as the rarest of all causes, malignant growth in the womb. Though

rare, it should be borne in mind. He then examined the interior of the woman's womb and found to his surprise that he had removed with the placental forceps a curious brainlike material which macroscopically was most suggestive of malignancy. Specimens were submitted to three different pathologists. Two thought it was chorioepithelioma. The third did not think it was, but as the history was so suggestive, and the appearance under the microscope so suspicious, he recommended hysterectomy. On the advice of the three pathologists and prompted by his own feelings, he removed the uterus. Inside of the womb, near the fundus, but not at the placental site, was to all macroscopic appearances a well developed neoplasm. This was studied carefully under the microscope, and the pathologists to whom it was submitted agreed that it was not chorioepithelioma, but were unable to decide what it was. There was an infiltration of necrotic material and granulation cells which formed a well marked tumor extending beneath the endometrium about half an inch and reaching into the myometrium about one quarter of an inch. He had, therefore, removed the woman's womb on a diagnosis of chorioepithelioma and the operation had proved it to be unnecessary. The patient made a good recovery. Dr. Hirst failed to see how the mistake was to be surely avoided. He considered it easy enough to diagnosticate well marked cases already "inoperable." It was desired, however, to make the diagnosis early. In every case of pathological condition of the endometrium after childbirth there might be seen the same multiplication of syncytial cells and the same invasion of the myometrium as in chorioepithelioma, and no one yet had been able to tell him how to distinguish between the two. By the microscopical appearance of scrapings from a case of retained placental fragments the diagnosis of chorioepithelioma might be justifiable. The only light on the question, in Dr. Hirst's opinion, was that, in addition to the microscopical findings, there must be present a large exuberant neoplasm in the uterus, profuse hæmorrhage, evidence of erosion of the uterine wall, and possibly metastasis. If, however, all these symptoms were waited for, operative results were not going to be particularly brilliant.

Dr. BLAND said that the diagnosis of chorioepithelioma was somewhat difficult, but from the history and the microscopical findings he thought as a rule a reasonably positive diagnosis ought to be made. Dependence should not, however, be placed upon the microscope alone, for the clinical manifestations he considered extremely valuable. To his mind a digital examination of the interior of the uterus was the best means at command to establish the true character of the lesion, though he did not think an absolutely positive diagnosis could even be made by the execution of this procedure. A characteristic of the growth which should be of help was that it was almost always in the fundal region and on the posterior wall. Moreover, the peculiar and characteristic conformation of the basal portion of tumor was so entirely different from that of other neoplasms that that in itself should strongly suggest the

presence of this tumor. Dr. Bland expressed his gratitude to Dr. E. E. Montgomery for the privilege of reporting the case, which had occurred in his service at the Jefferson Hospital.

Posttyphoid Ovarian Abscess.—Dr. BARTON COOKE HIRST reported the case of a young woman, who was admitted into a Philadelphia hospital with symptoms of typhoid fever. One month subsequently marked pelvic pain developed. Two months from the time of admission she was discharged. The pelvic pain continued for three months after her leaving the hospital, when she consulted the writer. He found marked abdominal tenderness, fever, a weak, rapid pulse, and to the right of the uterus an inflammatory mass of the size of an orange. A diagnosis of posttyphoid ovarian abscess was made, based upon the history and physical signs. Upon operation, the ovary was found converted into a single-chambered cyst which on bacteriological examination was found to contain a pure culture of colon bacilli.

Suppurative Cholecystitis with a Gallstone and an Intraperitoneal Abscess.—The second patient was a young woman who had recovered from an attack of typhoid fever. Three months previous to the author's seeing her she had noticed a lump below the ribs on the right side. On examination, a retroverted uterus and a prolapsed ovary were found. The following operations were done: Dilatation and curettement, ventrosuspension, and shortening of the infundibulopelvic ligament. The gall bladder was incised, and a stone and several ounces of pus were removed. An abscess in the peritoneal cavity below the gall bladder was also evacuated. The patient made an excellent recovery. The pus was submitted to a bacteriological examination and found to contain a pure culture of an unidentified bacillus of the colon group.

Dr. MUELLER said that the typhoid bacillus was probably always an inhabitant of the gall bladder during the attack of typhoid fever, producing a slight degree of cholecystitis in many cases, which disappeared upon the subsidence of the attack and required in the great majority of instances no treatment whatever. Sometimes suppurative cholecystitis occurred after typhoid fever, usually in a few weeks or months after the disease had subsided. In the last fifty-five bacteriological examinations in the German Hospital of bile aspirated during operations performed by Dr. Deaver, thirty-two cultures were obtained from the fifty-five, seven of which were typhoid bacillus in pure culture; of the others, in twenty-one the colon bacillus was obtained; in three the staphylococcus, and in one streptococcus. The typhoid bacillus produced widespread lesions of the gall bladder walls, cholecystitis being invariably found in the cases examined. Histologically, the gall bladder showed ulceration of the mucous membrane, serous and cellular infiltration of the walls, and a plastic exudate covering the serosa. In one case to which he had reference a fistula existed between the gall bladder and the stomach. He recalled a case in the service of Dr. Frazier, at the Philadelphia Hospital, of a girl of fifteen who

a year previously had had an attack of typhoid fever and had entirely recovered. She became pregnant, was delivered at term, and two weeks afterward had symptoms of severe cholecystitis. To all appearances she had been perfectly well, yet a calculus had developed within the gall bladder and did not give rise to trouble until a subsequent infection with the colon bacillus drove it into the cystic duct. In cases with a distinct history of typhoid fever it was clearly understood how the infection would be carried to the gall bladder by the blood, either of the general or portal circulation. In the other cases to which he referred there was no history of typhoid, yet there was a pure culture of the typhoid bacillus found in the gall bladder, and in those cases a consideration of the source of infection made it evident that there was some point of focal necrosis within the intestinal canal, not sufficient to give rise to any intestinal lesion, from which the bacillus was carried on to the gall bladder by the portal circulation, giving rise to the cholecystitis.

Myxomatous Degeneration of an Adenomyoma of the Uterus.—Dr. BARTON COOKE HIRST exhibited an illustration of this rather rare condition, the second case only that he had seen. Myxomatous change, he said, ranked among the rarest degenerations of fibroid tumors. Primary carcinoma of the clitoris is likewise rare. Carcinoma of the vulva anywhere was rare, but carcinoma of the clitoris was rarest of all. He had seen six cases of carcinoma of the vulva and only one of carcinoma of the clitoris. Primary carcinoma of the vagina was also rare. In the case referred to the disease attacked the posterior vaginal wall within the posterior commissure and extended two thirds of the way up the vaginal canal, leaving the anterior third of the vagina free of the disease. The most interesting question, in Dr. Hirst's opinion, was that of whether the uterus in all cases must be removed. He resected three inches of the rectum with the posterior two thirds of the vagina, but did not remove the uterus. The remnant of the vagina was made into a narrow canal to carry off the menstrual discharge. The patient recovered from the operation, but had passed from under observation.

Malignant Disease of the Uterus.—Dr. A. J. DOWNES showed a uterus removed the day before from a woman sixty years of age. The specimen showed the features which in some instances are considered "inoperable." The woman was from the South, and in last April had the first sign of hæmorrhage after ten years' cessation. Her case had been correctly diagnosed by a physician in the city, but advice given against an operation. An eminent gynecologist in New Orleans gave the same diagnosis and likewise advised against an operation. Dr. Downes saw her a week before, when she appeared to be in good physical condition. Examination revealed a small mass protruding below what should have been the posterior wall of the uterus, extending an inch down on the posterior wall. The anterior lip of the uterus could be made out. Vaginal and rectal

examinations showed a fixed mass at the site of the cervix. Dr. Downes did a panhysterectomy. He first sterilized the vagina and did not touch it again. The fundus of the uterus was perfectly normal, the cervix was twice the size of the fundus. He removed the uterus through the abdominal incision without the use of a ligature, and the closing part of the operation consisted in clamping off the vagina and leaving it shut. Six months before, the operation would have been an easy one and the case practically curable, for there was evidently no cancerous tissue left after the operation. The electrothermic clamp for hæmostasis was used and practically without loss of blood.

Book Notices.

Toxicology. A Manual for Students and Practitioners. By EDWIN WELLES DWIGHT, M. D., Instructor in Legal Medicine, Harvard University. Series Edited by VICTOR COX PEDERSEN, A. M., M. D., Instructor in Surgery and Anæsthetist and Instructor in Anæsthesia at the New York Polyclinic Medical School and Hospital, etc. Philadelphia and New York: Lea Brothers & Co., 1904. Pp. 298.

Students of medicine and of pharmacy have long felt the need of a comprehensive yet handy-sized textbook of toxicology, and an effort has been made to supply this want in the manual before us, which is one of the Medical Epitome Series intended for the use of students and of practising physicians. In Chapter I the author gives a general definition of the subject, and enumerates in the twelve succeeding chapters the principal poisonous substances, classifying and dividing them according to their physiological action. Thus, we have irritants, specific irritants, metallic irritants, vegetable irritants, animal irritants, poisonous foods, cerebral neurotics, spinal and cerebrospinal neurotics, depressants, asthenics, and ptomaines. The appearance and properties of the individual poison are described, followed by the symptoms of poisoning and the fatal dose, after which come methods of treatment, post mortem appearances, tests, and illustrative cases of poisoning, the latter usually taken from current medical literature.

The work is well arranged, but cannot be said to be quite up to date. In the treatment of carbolic acid poisoning, for example, we should expect to find some mention of the use of alcohol, but references to this are wanting, and the illustrative case of poisoning which is cited is twenty-three years old! In the chapter on ptomaines, the name of the discoverer of tyrotoxin—which, by the way, is not mentioned in the book—is spelled incorrectly. We have been rather disappointed to note a number of inconsistencies in nomenclature, together with numerous minor typographical errors, which must be attributed to faulty proof reading. The chemical symbols employed by the author here and there throughout the work are also open to suspicion, that referring to potassium bitartrate, in particular, being wholly unintelligible. We mention these defects in order that the author may be led to improve the work in subsequent revisions. The newer

synthetic remedies, which are occasionally poisonous, are wholly ignored in the volume, and a chapter on the poisonous properties of such of them as have been found to possess such properties would improve the book.

Physiological Economy in Nutrition. With Special Reference to the Minimal Proteid Requirement of the Healthy Man. An Experimental Study. By RUSSELL H. CHITTENDEN, Ph. D., LL. D., Sc. D., Director of the Sheffield Scientific School of Yale University and Professor of Physiological Chemistry; Member of the National Academy of Sciences, etc. New York: Frederick A. Stokes Company, 1904. Pp. xiv+478. (\$3.00 net.)

The author states very truly that there is no subject of greater physiological importance or of greater moment for the welfare of the human race than that of nutrition. Almost daily the physician is asked how best to maintain the body in a condition of health and strength, and yet there are widely divergent views as to the extent and character of food requirement. While certain dietary standards have been accepted, frequently persons in good physical condition are seen whose diet varies materially from the standard.

The author has sought a more definite knowledge of the true physiological necessities of the body for proteid foods, because if accepted ideas are exaggerated in regard to the daily quantities of these foods necessary to maintain health and strength, then a physiological economy is possible. Fats and carbohydrates, when oxidized in the body, are ultimately burned to simple gaseous products, viz., carbonic acid and water. When proteids are oxidized they yield a series of crystalline nitrogenous products that, while ultimately excreted by the kidneys, are in the body fluids, or may be deposited temporarily and exercise a more or less deleterious influence on the system.

The experiments, which were arranged with great care, were conducted with three classes of individuals: 1. A group of five men connected with Yale University as professors and instructors. 2. A detachment of thirteen men from the hospital corps of the army. 3. A group of eight athletic students. The results of the experiments are tabulated in detail, and show that ordinarily people "consume much more food than there is any necessity for, and that it is more than probable that this excess of food is in the long run detrimental to health, weakening rather than strengthening the body, and defeating the very objects aimed at." The proof is conclusive that the amount of proteid or albuminous food needed daily for the actual physiological wants of the body is about one half the quantity that is consumed by the average man; in other words, 59 grammes of proteid food is adequate for such want under ordinary conditions of life.

The conclusions indicate that the man whose work is mainly mental has no need for high fuel values in his daily ration, because he can maintain bodily equilibrium on far less than 3,000 calories a day. And while a man who must labor hard may need a greater quantity of fats and carbohydrates than is necessary to yield 3,000 calories, one who does a moderate amount of physical work has no apparent need for such fuel value in food.

The work is a most important contribution to dietetics and does great credit to its distinguished author.

A Practical Treatise on Diseases of the Skin. For the Use of Students and Practitioners. By JAMES NEVINS HYDE, A. M., M. D., Professor of Skin, Genitourinary, and Venereal Diseases, Rush Medical College, Chicago; Dermatologist to the Presbyterian, Augustana, and Michael Reese Hospitals of Chicago, etc.; and FRANK HUGH MONTGOMERY, M. D., Associate Professor of Skin, Genitourinary, and Venereal Diseases, Rush Medical College, Chicago; Professor of Skin and Venereal Diseases, Chicago Clinical School, etc. Seventh and Revised Edition. Illustrated with 107 Engravings and 34 Plates in Colors and Monochrome. Philadelphia and New York: Lea Brothers & Co., 1904. Pp. 938.

The authors have expended a great deal of labor in the preparation of the latest edition of this textbook of dermatology. Every subject has been given the benefit of the latest researches in a most actively cultivated specialty. A number of new diseases have been added and, while the nomenclature remains cumbersome and the synonyms are in various languages, this is necessary in the present stage of our knowledge of the subject and the international interests of the contributors. The chapters devoted to radiotherapy, phototherapy, and general pathology of the skin are clear and suggestive. It is rather disappointing to find, in view of Sabouraud's recent work in clearing up the confusion in regard to pityriasis and seborrhea of the scalp, that the errors of the Vienna school are still endorsed. It is a pity that a volume of nearly 1,000 pages should be printed upon such heavy paper; six pounds in a book is rather unwieldy and might well justify a division into two volumes. The half tone illustrations are very good, which cannot be said of the colored plates. Any lithograph of a skin lesion is subject to the personal interpretation of the artist who makes the painting, of the lithographer who prepares the stone, and of the artisan who prints the plates, with an inevitable disappointment and expense to every one. These may be platitudes, but the increased cost of lithographs to the reader is not justified by their value, which is nothing unless they are facsimiles. As a whole the volume deserves the warmest praise, and the authors should receive congratulations upon the full maturity of a treatise the first edition of which appeared just twenty-one years ago.

The Surgical Treatment of Bright's Disease. By GEORGE M. EDEBOHLS, A. M., M. D., LL. D., Professor of the Diseases of Women in the New York Postgraduate Medical School and Hospital, etc. New York: Frank F. Liseicki, 1904. Pp. 332.

The operation of decapsulation of the kidney is the subject of this work. The author's name is everywhere prominently associated with this procedure, though an unfortunate controversy has arisen as to the title to priority in its employment.

Of necessity, considerable space in the book is devoted to this controversy. Whatever may be any reader's opinion of the merits of the question, it must be conceded that Dr. Edebohls has written of it temperately and with dignity.

As to the value of the operation itself, it must be said to be still *sub-judice*, with perhaps a growing tendency to look upon decapsulation as probably of little permanent efficacy in arresting any one of the various morbid conditions of the kidney familiarly grouped under the name of Bright's disease. But our experience must be much greater than it is now before we can decide that the operation is not a hopeful resource.

Applied Materia Medica. A Textbook Intended for the Use of Nurses in Hospital Training Schools. By J. HENRY SCHROEDER, Ph. G., M. D., formerly Lecturer on Materia Medica in the Jewish Hospital Training School for Nurses, Cincinnati. Cincinnati: The Robert Clarke Company, 1904. Pp. ix+113. (\$1.25.)

The author of this little manual has contrived to bring together within a very small compass a remarkable amount of information concerning the drugs commonly used in wards and sick rooms. The descriptions of drugs are necessarily abbreviated, but they have lost none of their scientific value in the process of condensation, and the matter is presented in a manner that makes reading easy, quite fulfilling the wish of the author "that the nurse may pursue with pleasure and profit the study of this subject" (*materia medica*). It is a book that can be confidently recommended to students of nursing and to those having to do with the teaching of nursing.

BOOK AND MAGAZINE NOTES.

One Hundred Years of Publishing is a handsome little volume giving the history of the house of William Wood & Company, the second oldest publishing establishment in New York. The booklet is neatly printed and handsomely illustrated with portraits and pictures of the various establishments Messrs. Wood have occupied.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Die Angeborene Pylorusstenose im Sauglingsalter. Von Dr. JUSSUF ISRAHIM, Privatdozent für Kinderheilkunde. Mit 1 Tafel und 1 Abbildung im Text. Berlin, 1905: S. Karger. Pp. 120. [M. \$3.50.]

A Treatise on Diseases of the Nervous System. By L. HARRISON METTLER, A. M., M. D., Associate Professor of Neurology, College of Medicine of the University of Illinois; Professor of Nervous and Mental Diseases in the Chicago Clinical School, etc. Complete in One Volume. Profusely Illustrated. Chicago, 1905: Cleveland Press. Pp. 989.

Ten Lectures on Biochemistry of Muscle and Nerve. By W. D. HALLIBURTON, M. D., F. R. S., Professor of Physiology, King's College, London; Editor of Kirke's Handbook of Physiology. With Illustrations. Philadelphia, 1904: P. Blakiston's Son & Co. Pp. xvi+160. [\$2.00 net.]

Manson's Eye Worm of Chickens (*Oxyspirura Mansonii*). With a General Review of Nematodes Parasitic in the Eyes of Birds, and *Notes on the Spiny-suckered Tape-worms of Chickens.* By B. H. RAMSON, B. Sc., A. M., Scientific Assistant in Charge of the Zoological Laboratory Bureau of Animal Industry. Washington, 1904: Government Printing Office. Pp. 72.

Miscellany

Reaction Times as a Test of Mental Ability.—Whipple, in the *American Journal of Psychology*, for October, 1904, summarizes his article as follows:

1. The reaction experiment, as conducted in the psychological laboratory, is primarily a qualitative experiment for the synthesis of the action consciousness. When due regard is paid to the objective conditions, to practice, and to the direction of attention most observers can readily be trained to adopt any of the three types of attention. The quantitative results are uniform for all observers for a given direction of the attention.

2. The reaction experiment of the anthropometric type, as conducted upon school children, is a rough and ready quantitative experiment which has yielded results of very questionable value as adjudged by the laboratory standards. The constant individual differences between groups of children, which have sometimes been assumed to indicate differing grades of mental ability or general intelligence, are largely the products of faulty experimental conditions and cannot in any event be referred either in theory or practice to constant individual differences in mental ability.

3. This examination of the reaction experiment suggests that many other experimental studies of school children have been vitiated by the neglect of those cautious in procedure and interpretation that laboratory practice has taught. As an illustration, the pitch discrimination of an unmusical observer is shown to be subject to wide variation when the test conditions are slightly modified.

4. The outcome of the reaction time test (and indeed of any psychophysical test) upon school children will depend not only upon the objective conditions of the test, upon the nature of the instructions given, etc., but also to an appreciable extent upon the ability of each child to understand and carry out the instructions given. When, therefore, a test is affected in this way, any assumed correlation between the quantitative results and the general intelligence of the group of children tested is in reality but a correlation of general intelligence with itself.

The Psychology of Day Dreams.—Smith, in the *American Journal of Psychology*, for October, 1904, summarizes his study of this subject in the following observations: Day dreaming appears to be a normal and well nigh universal phenomenon in children and adolescents, and may continue throughout life. It is especially characteristic of the years of adolescence. The content of the day dream is chiefly determined by environment, though its forms like those of night dreams are influenced by age, health, and degree of mental development. In early childhood day dreams are usually made up of memory images, actual experiences or stories being reproduced with little

change. The latter tendency is further illustrated by the insistency of children that stories told to them shall be repeated without any change in the details. The future of childhood is usually a definitely circumscribed and near future, and motor activities and eating figure largely in the content of childish dreams. With the dawn of adolescence the variety and complexity of content is increased and the range is widened. Dreams of the future are usually of the vague future with boundless possibilities. The instinct emotions become an evident factor, and dreams of love are frequent. Altruistic and egoistic emotions are both greatly intensified. The day dreams of adult life show a closer connection with actual life than those of childhood and adolescence. Dreams of the future were more in the form of plans with the possibility of accomplishment. The day dreams of old age are infrequent and are usually concerned with the remote past. Though environment exercises an important influence upon the development of the imagination and there is a possibility that it may be dwarfed and starved by repression, much is due to differences of mental endowment, and day dreaming in a marked degree is often associated with high intellectual endowments and creative ability. Day dreaming like any other mental activity may become excessive and pass over into pathological states, and in consequence of the fact that it is usually enjoyable, and a passive state, it is peculiarly liable to this source of danger. Sex differences are especially marked in day dreams, many of them being so characteristically masculine or feminine that the sex of the writer is unmistakable. While this is in part undoubtedly due to environment and conventional training, it also suggests that in the more automatic workings of the mind there may be a fruitful field for the investigation of the question of how far mental differences between men and women are innate and fundamental, and how far they are due to artificial causes.

Mania.—Wernicke, in the *Alienist and Neurologist*, for November, 1904, observes that in addition to mania there are maniacal states which are phases of composite psychoses occurring in stages or combinations of two or more fundamental forms. Mania may be related to melancholia in three ways:

1. A mild form of the one disease generally appears in the convalescence of the other and terminates it. The duration of this change, which often appears after the patient's condition has apparently become normal, may be a few days or a few weeks. 2. Mania is the most inclined to recur of all the psychoses. Years usually elapse between the early attacks, then the intervals become shorter, and finally the periods of disease may exceed in duration those of health. A similar experience is rarely observed in melancholia. Occasionally, instead of a recurring mania there is a melancholia which partakes of the better prognosis of mania. Occasionally, also, a melan-

cholia may be succeeded by a mania, this being known as the representative melancholia. 3. A combination of mania and melancholia frequently occurs in which one seems to be excited by the other. They are separated by an interval of apparent health which may last for days and weeks, or the period may be very brief and escape observation. This disease has been termed circular mental disease, or *folie à double forme*. Its prognosis is very bad, and in many cases it seems to be incurable.

The treatment of mania is usually impossible outside of a hospital for the insane. Acute pure mania never becomes chronic mania, which is a particular form of disease. Chronic mania has all the essential characteristics of acute mania, but they are so modified that the conditions of a chronic stable condition are combined with it.

Concerning Death from Chloroform.—Stiles and MacDonald, in *Fortschritte der Medezin*, for October 10, 1904, observe that inasmuch as death seldom comes as a late result of the use of chloroform as an anæsthetic, it is not improbable that there was a preëxisting cause in case of such death which may be looked upon as a predisposition to the unfavorable result. Such a predisposing factor may be found in some precedent condition of disease or in a peculiar idiosyncrasy to chloroform. Liver disease is a cause which must never be overlooked. According to Guthrie, fatty degeneration of the liver is the real predisposing factor, and chloroform simply intensifies it. The authors are not convinced, however, that fatty degeneration of the liver may not be due to the action of chloroform upon an organ which was previously healthy. The predisposing factor is believed by other writers to reside in diseased kidneys, a diseased vascular system, or in some other organ. On the other hand, some individuals who have severe organic lesions withstand chloroform readily. Preëxisting lesions are therefore not necessarily a contraindication to the use of chloroform. It is quite probable that idiosyncrasy plays an important part in the use of this substance. Many writers ascribe to chloroform a directly destructive action upon the red corpuscles, oxidation being deficient, and this leading to the deposit of fat within the organs. The more probable explanation is to be found in its poisonous effect. Chloroform is an intense poison to protoplasm, and is thus likely to cause changes in the organs and interrupt their functions. Experimental investigations with chloroform revealed fatty degeneration in the liver, kidneys, and heart, and it probably was present in other organs, but it was not certain that the fatty liver did not result from infiltration rather than degeneration. The symptoms of late chloroform poisoning resemble those of other auto-intoxications, for example, diabetic coma. There has also been observed an increase of acetone in the urine, and the most recent physiological investigations seem to show that the fat and not the albumenoids or carbohydrates is the source of this substance.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending January 6, 1905:

Smallpox—United States.			
Place.	Date.	Cases.	Deaths.
Colorado—Larimer County.	Nov. 1-30.	1	1
Dist. of Columbia—Washington.	Dec. 24-31.	1	1
Illinois—Chicago.	Dec. 24-31.	11	3
Illinois—Danville.	Dec. 17-31.	2	1
Michigan—at 32 localities.	Dec. 17-31.	Present.	
Missouri—St. Louis.	Dec. 17-23.	18	1
South Carolina—Georgetown.	Nov. 16-Dec. 31.	8	
Tennessee—Memphis.	Dec. 24-31.	3	
Tennessee—Nashville.	Dec. 24-31.	8	Two cases imported.
Smallpox—Foreign.			
Austria—Prague.	Dec. 3-10.	15	
Ecuador—Guayaquil.	Dec. 7-14.	1	1
France—Lyons.	Dec. 3-10.	1	
France—Paris.	Dec. 10-17.	4	1
Great Britain—London.	Dec. 10-17.	2	
Gt. Britain—Newcastle-on-Tyne.	Dec. 10-17.	19	
Great Britain—South Shields.	Dec. 10-17.	5	2
India—Bombay.	Nov. 31-Dec. 6.	14	1
Italy—Catania.	Dec. 8-15.	1	
Italy—Milan.	Oct. 1-31.	1	
Mexico—City of Mexico.	Nov. 19-Dec. 10.	3	1
Norway—Christiania.	Dec. 10-17.	1	1
Russia—Moscow.	Nov. 27-Dec. 8.	1	2
Russia—Odessa.	Dec. 3-10.	1	
Russia—St. Petersburg.	Dec. 3-10.	5

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending January 4, 1905:

- BROOKS, S. D., Surgeon. To report on January 10, 1905, to chairman of board of examiners at Fort Stanton, N. M., for the purpose of determining his physical condition.
- BROWN, F. L., Pharmacist. Granted leave of absence for thirteen days from December 19, 1904. Granted extension of leave of absence for two days from January 1, 1905.
- GREGORY, G. A., Acting Assistant Surgeon. Granted leave of absence for seven days from December 30, 1904.
- GREENE, J. B., Passed Assistant Surgeon. Granted extension of leave of absence for seven days from January 3, 1905.
- LINLEY, W. J., Acting Assistant Surgeon. Granted leave of absence for thirty days from January 16, 1905.
- LUMSDEN, L. L., Passed Assistant Surgeon. Relieved from duty at the Immigration Depot, New York, N. Y., and directed to proceed to Philadelphia, Pa., and report to the Medical Officer in Command for duty. December 29, 1904.
- NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for seven days from December 25, 1904, under paragraph 191 of the regulations.
- SALMON, T. W., Assistant Surgeon. Relieved from duty at Philadelphia, Pa., and directed to proceed to the Immigration Depot, New York, and report to Surgeon G. W. Stoner for duty. December 29, 1904.
- WAKEFIELD, H. C., Acting Assistant Surgeon. Granted leave of absence for three days, under paragraph 210 of the regulations.

Boards Convened.

Board convened to meet at Washington, D. C., January 5, 1905, for the physical examination of candidates for the position of Second Assistant Engineer, Revenue Cutter Service. Detail for the board—Assistant Surgeon-General G. T. VAUGHAN, chairman. Assistant Surgeon A. J. McLAUGHLIN, recorder.

Board convened to meet at Fort Stanton, N. M., January 10, 1905, for the purpose of making a physical examination of Surgeon S. D. BROOKS. Detail for the board—Surgeon P. M. CARRINGTON, chairman. Assistant Surgeon NORMAN ROBERTS. Assistant Surgeon H. G. EBERT, recorder.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 7, 1905:

ELMER, M. K., Assistant Surgeon. Detached from the *Hancock* and ordered to the Naval Hospital, New York, N. Y., for treatment.

FEREBEE, N. M., Medical Director. Having been examined by a retiring board and found incapacitated for active duty, on account of physical disability incident to the service, retired from active service on December 31, 1904, under Section 1453, Revised Statutes.

McMURDO, P. F., Acting Assistant Surgeon. Detached from the Navy Yard, League Island, Pa., and ordered to the Naval Recruiting Station, Baltimore, Md.

PAYNE, J. H., Passed Assistant Surgeon. Detached from the *Marietta* and ordered home to await orders.

ROSS, JOHN W., Medical Director. To be placed on the retired list on January 11, 1905, under provisions of Section 1444, Revised Statutes, upon which date he will reach the age of sixty-two years. Ordered to continue duty with the Isthmian Canal Commission after retirement.

STEELE, JOHN M., Surgeon. Detached from the Naval Recruiting Station, Baltimore, Md., and ordered to the *Colorado* on January 10, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending January 7, 1905:

BYRNE, CHARLES B., Colonel and Assistant Surgeon General. Detailed a member of the army retiring board to meet at Fort Leavenworth, Kan., vice George W. Adair, Lieutenant Colonel and Deputy Surgeon General, relieved.

DAVIS, WILLIAM B., Major and Surgeon. Relieved from duty at Honolulu, Hawaii, and ordered to the Philippine Islands for duty.

DEVEREUX, J. R., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Meade, S. D., and ordered to Fort Logan, Colo.

FARR, CHARLES W., First Lieutenant and Assistant Surgeon. In addition to his present duties will perform the duty of attending surgeon, San Francisco, Cal.

GER, CHARLES C., First Lieutenant and Assistant Surgeon. Retired from active service on account of disability incident thereto.

MEARNS, E. A., Major and Surgeon. Granted thirty days' leave, to take effect upon expiration of his present sick leave.

OWEN, W. O., Major and Surgeon. Ordered to Fort Leavenworth, Kan., for examination by an army retiring board.

REILLY, JOHN J., First Lieutenant and Assistant Surgeon. Ordered to proceed from Jackson Barracks, Louisiana, to the United States Army General Hospital, Fort Bayard, New Mexico, for treatment.

SILER, JOSEPH F., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Logan, Colo., and ordered to Fort Meade, S. D., for duty.

WOODSON, R. S., Captain and Assistant Surgeon. Relieved from duty at Fort Clark, Texas, and upon discharge from the Army and Navy General Hospital, Hot Springs, Ark., ordered to Fort McDowell, Cal., for duty.

YOST, JOHN D., First Lieutenant and Assistant Surgeon. Relieved from duty at San Francisco, Cal., and ordered to Honolulu, Hawaii, for duty, relieving William B. Davis, Major and Surgeon.

Births, Marriages, and Deaths*Born.*

GOLDBERG.—In Buffalo, N. Y., on Saturday, December 31st, to Dr. and Mrs. Jacob Goldberg, a son.

Married.

FULLER—THOMSON.—In St. Louis, Missouri, on Wednesday, December 28th, Dr. Allen Garfield Fuller and Miss Holmes Lackland Thomson.

PERRY—CREW.—In New Orleans, Louisiana, on Wednesday, December 28th, Dr. C. Seldon Crew and Miss Iris Perry.

PROPPER—PROPPER.—In Camden, New Jersey, on Thursday, December 29th, Dr. Julius Propper and Miss Gizelle Propper.

RHOME—PETERSON.—In Philadelphia, on Wednesday, January 4th, Dr. Byron Luther Rhome and Miss Lily Blanche Peterson.

SEEBASS—THIES.—In Denver, Colorado, on Monday, December 19th, Dr. Alfred R. Seebass and Miss Herta Thies.

WALDEN—BURWELL.—In New York, on Monday, December 26th, Dr. Richard Channing Walden and Miss Daisy Bissell Burwell.

WALKERTON—JOHNSON.—In Washington, D. C., on Wednesday, December 28th, Dr. Bathurst B. Bagby Walkerton and Miss Alpie C. Johnson.

Died.

ADAMS.—In Washington, D. C., on Sunday, January 1st, Dr. Arthur C. Adams, in the fifty-first year of his age.

ANDERSON.—In Chicago, Illinois, on Saturday, December 24th, Dr. Axel Morris Anderson, in the thirty-third year of his age.

BARNUM.—In Cassville, N. Y., on Sunday, January 1st, Dr. David Albert Barnum, in the sixtieth year of his age.

BEALE.—In Charlottesville, Virginia, on Thursday, December 29th, Dr. C. W. Beale, in the eighty-first year of his age.

BEEBE.—In Chicago, Illinois, on Friday, December 30th, Dr. Ellen Beebe, in the fifty-sixth year of her age.

CALDWELL.—In Pittsburgh, Pennsylvania, on Tuesday, December 20th, Dr. Merlin Caldwell, in the thirty-first year of his age.

DEVORE.—In Ripley, Ohio, on Thursday, December 29th, Dr. Earl Devore, in the twenty-seventh year of his age.

EAGLETON.—In Ocala, Florida, on Wednesday, January 4th, Dr. James M. Eagleton, in the seventieth year of his age.

GRIFFIN.—In Philadelphia, on Sunday, January 1st, Dr. Frederick Griffin, in the forty-ninth year of his age.

HOYL.—In Fort Valley, Georgia, on Monday, December 26th, Dr. J. D. Hoyl.

JONES.—In Clayville, N. Y., on Sunday, December 25th, Dr. J. E. Jones, in the seventy-third year of his age.

MINTON.—In New York, on Monday, January 2nd, Dr. D. S. Minton, in the sixty-sixth year of his age.

O'HARA.—In Buffalo, N. Y., on Sunday, January 1st, Dr. Arthur P. O'Hara, in the forty-fourth year of his age.

PATRICK.—In St. Paul, Minnesota, on Friday, December 30th, Dr. J. B. Patrick, in the forty-ninth year of his age.

PHOLON.—In San Francisco, California, on Thursday, December 29th, Dr. William Pike Phelon, in the seventy-first year of his age.

POMEROY.—In St. Louis, Missouri, on Friday, December 30th, Dr. John Reynolds Pomeroy, in the fifty-sixth year of his age.

RAY.—In Denver, Colorado, on Friday, December 30th, Dr. John Ray, in the forty-eighth year of his age.

ROSS.—In Kansas City, Kansas, on Saturday, December 31st, Dr. William Alexander Ross, in the eighty-eighth year of his age.

SMITH.—In Brooklyn, N. Y., on Tuesday, January 3rd, Dr. Evan F. Smith, in the fifty-fourth year of his age.

SMITH.—In Louisville, Kentucky, on Saturday, December 31st, Dr. Richard Henry Smith, in the sixty-seventh year of his age.

WILKINSON.—In Louisville, Kentucky, on Saturday, December 31st, Dr. Monroe Wilkinson, in the sixty-eighth year of his age.

WOOD.—In Owensboro, Kentucky, on Monday, January 2nd, Dr. A. C. Wood, in the eighty-first year of his age.

YOUNG.—In St. Louis, Missouri, on Thursday, December 29th, Dr. Hiram W. Young, in the thirty-fourth year of his age.

Lectures and Addresses.

THE ABUSE OF WATER DRINKING IN DISEASE.*

By MORRIS MANGES, A. M., M. D.,

NEW YORK,

PROFESSOR OF CLINICAL MEDICINE, NEW YORK POLYCLINIC MEDICAL SCHOOL; VISITING PHYSICIAN TO MOUNT SINAI HOSPITAL.

In accepting your president's invitation to address you this evening, it seemed best to me to select some topic of every day interest. I have, therefore, decided to consider briefly the abuse of water drinking, especially as prescribed by physicians.

In what I have to offer on this subject there will be but little that is new, inasmuch as the facts set forth are available to all of you in the textbooks which are accessible. Unfortunately, however, too many physicians are indifferent about acquiring information at first hand and prefer rather to follow the crowd or some popular opinion as they successively take up some new shibboleth. This idea they will follow as a fad and use in a most careless and indiscriminate way. Failing to get good results, instead of studying the cause of the failure, they will decry the method. The results of investigations made by careful students they will pass by unheeded and they will scorn or ridicule any precise directions. In the recoil which follows their over enthusiastic faddism they not only destroy their own efforts; but unfortunately, the carefully and slowly gathered results which are based upon real investigation are set at naught and lost.

The abuse of water drinking is not, as is usually supposed, an American vice, but is practised in every part of the world. It is not by any means confined to the city, but is seen in its full glory at the various mineral springs, where the temptation to "drink all you wish for five cents!" seems too great to be resisted. To what extremes this

water drinking at the spas can be driven I myself saw ten years ago at a famous New England spring, where the "champion water drinker" of this resort, a chronic nephritic, whose record was sixty-five goblets a day, was pointed out to every visitor and his feat considered one to be emulated. That such extremes may easily be followed by fatal results is proved by the deaths which have been reported after following the "water cure" of Cadet de Vaux, who recommended for gout the drinking of six to eight ounces of water as hot as possible every quarter of an hour; forty-eight drinks of this kind, that is, about ten litres, to be taken during the day.

Before considering the abuse, it may not be amiss to point out briefly some of the accepted facts about the effects of water drinking in health and in disease. This subject is one which is full of difficulties, since many of the older researches must now be modified in the light of the newer doctrines of osmosis, electrolytic phenomena, etc. The uncertainty of our views on the subject and on the causation of œdema and dropsy, the exact definition of hydræmia and plethora, etc., has been well shown by Kraus in his recently published treatise on *The Dietetic Treatment of Cardiac Diseases*.¹

Water once within the body is no longer water, but must be considered in its relations to the various salts, colloids, etc., with which it comes in such intimate contact.

The normal quantity¹ of water for the healthy adult individual, exclusive of the water contained in the food, is about one and one half to two litres a day. Of this two thirds appears in the urine, one third being retained in the body.

Only a small portion of the water which is taken is absorbed by the stomach, the maximum quantity being ten per cent.; the other ninety per cent. is passed on into the intestines. A fact which is seldom recognized is that not only is the absorption of water in the stomach very slight, but that even the excretion of water into

* Read at a meeting of the New York County Medical Association.

¹ *Handbuch der Ernährungstherapie*, von Leyden und Klempner, 1903, Vol. 41, p. 366.

the stomach may take place under the conditions pointed out by von Mering.

Another most important fact is that every drop of water introduced into the system must be excreted from it, directly or indirectly, by the heart; hence the larger the quantity of liquid introduced, the greater the amount of energy demanded of the heart for its disposal.

Water drinking has certain effects on the body, as is well stated by Hoffmann.² The functions which are principally affected are first, the metabolism; second, the temperature; third, the circulation, especially the heart; fourth, the glandular secretions; and, fifth, the peristalsis. The most important of these are the metabolism and the circulation.

The effects upon the metabolism are contradictory, but the following may be accepted:

"The increased drinking of water does not increase the breaking down of the albumins. It is true that such an increase causes a greater excretion of urea, but this does not depend upon the increased production of urea, since the effects disappear very promptly if the increased drinking of water is continued for several days; hence it cannot be doubted that this is only dependent upon a greater washing out of urea, which, however, is only a temporary effect. The question is a difficult one. I am inclined to agree with the views of von Noorden, which are expressed as stated. Nevertheless, the metabolism as a whole must be distinctly increased, as may be inferred from the effect upon the heart, the circulatory activity, and the peristalsis. This increase of metabolism after the free drinking of water takes place, especially at the expense of the carbohydrates and fats."

The effects upon the circulation have been well shown by Baruch,³ who emphasizes the importance of considering the relations of temperature, the quantity taken, and the duration of the contact of the water with the mucous membrane. Taken in small quantities hot water raises the pulse rate and lowers the blood pressure; cold water diminishes the pulse rate and raises the blood pressure; lukewarm water (that is, at a temperature of 77° to 86° F.) lowers blood pressure. *Water at ordinary temperature (60°) has very little effect.* These effects cease in about twenty minutes. They are due to the influence exerted upon the vasomotor centres rather than to a dilution of the blood. The greater the quantity of water above 200 c.c., the greater the effect

upon the blood vessels. This effect, however, does not last longer than three minutes. The imbibed water begins to appear in the tissues within an hour and the entire quantity is eliminated in three and one half hours.

Diuresis does not depend upon the quantity of water introduced into the body, but upon the blood pressure in the kidneys. Excretion is also influenced by the temperature of the body, as is well shown by the report of Sahli, quoted by Baruch,⁴ who found that in hypodermoclysis in cases of mercurialism the diuretic effect ceased as soon as the patient had fever.

Finally as regards the mysterious relation of water drinking at meals to obesity. This resolves itself into the very simple explanation given by Oertel and Schwenninger, that this depends merely upon the fact that more food can be eaten when a large quantity of water is taken with meals, and less food is relished when the quantity of water at the meals is very much diminished.

Turning to the practical side, it may seem paradoxical to say that the abuse of water drinking has already been discussed in the presentation of the above. These abuses are committed by every one of us in his routine work. Usually no harm is done, even though we fail to achieve the results desired. But the contrary is true in the not infrequent cases where we add to the burdens of an already taxed heart and circulation, and where we thoughtlessly augment the embarrassments of organs we are striving to relieve.

I do not propose to consider all of these conditions, but I will direct your attention to only the more important of them.

Most striking of all is the abuse of water drinking in chronic nephritis. Patients require no urging to drink as much as possible, since the laity firmly believe that copious libations and the treatment of Bright's disease are synonymous. The larger the quantity of water consumed, according to the patient's reports, the more benignant and encouraging becomes the attitude of the attending physician. That any harm might follow such a course is beyond his belief. To doubt the efficacy of "kidney flushing" is the rankest heresy; that good might even result from reducing the daily amount of fluids to normal quantities is incomprehensible. And yet such is the case. It is to von Noorden⁵ that we are indebted for having called attention to this, and for having had investigations made by several of his pupils (Ritter, Dapper, Rzetkowski, and Mohr) to corroborate his contentions that when the heart

⁵ *Sammlung klinischer Abhandlungen*, 2. Heft, pp. 56 to 63.

is no longer competent, the daily quantity of water should be restricted to one and one quarter litres (not including the water contained in the food, which averages 500 to 700 c.c.).

In the earlier stages, also, when good compensation exists, this restriction is advisable as a prophylactic measure. Von Noorden has proved that in both stages the elimination of the important salts is not lessened by this restriction. Even in the nephritis of diabetes he does not hesitate to restrict fluids when the cardiac condition demands it.

In the early days of this restriction the patients often complain of thirst, which, however, soon disappears. On one day in the week the patient is allowed to drink as much as he pleases. This insures the removal of any nitrogenous salts which might perchance have accumulated.

Von Ziemssen has also observed good results from the restriction of fluids in contracted kidneys, especially in cases where there are distinct evidences of arteriosclerosis.

Ewald could also corroborate von Noorden's views.

My own experience during the past few years has been the same, as the results obtained in these cases have been decidedly better since the use of water has been more rationally controlled.

Von Noorden has also observed cases of chronic parenchymatous and even acute nephritis in which the regulation of water has been useful. Baruch⁶ also emphasizes the importance of this in acute nephritis and prefers the use of small quantities of cold water every half hour. "If the enormous labor which this overfilling of the system with fluids inflicts upon the embarrassed circulation is considered, it would not be difficult to see the advantage of smaller quantities given for reflex effect. Comparison of clinical results has too frequently convinced me of the superiority of the latter method."

In heart diseases the abuse of fluids is less evident, but none the less serious in its consequences. Not only do many physicians fail to reduce fluid in these patients, but they even order flushing at the spa and at home to patients with gout, chronic rheumatism, gravel, hepatic and gastric disorders, etc., who have manifest or undetected organic disease. This is especially true at the spas where the routine use of stencilled treatments wrecks many a compensation or converts latent into actual cardiac disease.

To quote from a former paper on The Causes of Failure of Compensation in Diseases of the

Heart,⁷ which I read before the Academy of Medicine in 1900: "Many a compensation is shattered at Carlsbad and other resorts under the so called guidance of physicians. How many more are wrecked by the patient's own efforts in Banting, thyroid medication, etc.! Far too many paunches are flattened, livers shrunken, and gall bladders cleansed, dyspepsias cured, vain women's figures restored to youthful lines and suppleness with the high sacrifice of cardiac compensation. Small wonder, then, that Carlsbad physicians are now sending their patients to Nauheim for the after cure!"

The other abuse of water drinking in cardiac diseases lies in the failure to reduce the quantity of fluids. I refer to the value of the dry diet in many of these cases.

The significance of the influence of water drinking may be appreciated if we consider the striking results in Dennig's researches.⁸ After placing four adult individuals in nitrogenous equilibrium under a normal diet, they were subjected to several successive periods of alternate normal quantity of fluid (that is, about 2 litres), and periods of six days during which the amount of fluid allowed was reduced to half a litre. On the six days during which the normal amount of liquid was allowed, the amount of water excreted varied between 49 and 71 per cent., whereas during the dry periods the amount was increased to from 111 to 173 per cent. The far reaching inferences from these experiments need no further comment. Their practical significance is attested by the good results which often follow the restriction imposed by the dry diet. The chronic hyperæmia of the kidney, the existence of dropsy, and the hydræmic plethora, and anæmia in advanced cardiac conditions are sufficient indications of the need of great care in warning patients against too much liquid in these conditions. As already stated, every drop of water taken into the body means additional work for the heart. Our aim is to regulate the blood pressure in the kidney rather than to crowd more work upon the already struggling heart by carelessness in fluid regulation. Indeed, the cardiac tonics often reassert their action if the quantity of fluid is restricted.

In chronic gastric and intestinal disorders the significance of this abuse can be more readily recognized; but, nevertheless, the warnings are unheeded. Many a patient bears within him the indelible records of what Salisbury and Banting régimes can do. So, too, have marks been left by the milk diets which have been imposed upon

⁶ *Loc. cit.*, p. 292.

⁷ *Medical Record*, February 16, 1901.

⁸ Quoted in detail by Kraus, *loc. cit.*, p. 365.

feeble women and men, the splashings of whose large atonic stomachs have fallen upon deaf ears. Their physicians pay just as little heed to the significance of the small amounts of urine secreted by patients with dilated stomachs, or to the importance of von Mering's researches that water may even be excreted into such stomachs. Of what significance is the fact which they all learned at the medical school that the stomach practically absorbs but little water, provided they can induce these patients to drink freely? Water out of sight is out of such physicians' minds!

As regards the effects of large quantities of water in metabolic disorders, the abuse of water drinking will last till patients and their doctors worship at other shrines than that of their mystic Baal, uric acid. I have already given the views of Hoffmann upon the effect of water drinking on the metabolism. I shall also give those of the distinguished Berlin physiologist, Rubner, who says:⁹ "Formerly a distinct influence upon the metabolism was attributed to water drinking, and it was supposed that the splitting up of albumins was decidedly increased by it. This, however, is incorrect. Copious water drinking may for a short time cause a washing out of nitrogenous products from the body; but water has no effect upon the splitting up of the albumins and upon the general metabolism."

Furthermore, as regards the excretion of uric acid, Minkowski¹⁰ has shown that the older researches are valueless, since the uric acid tests fail to react when the urine is too dilute. He also quotes the researches of Schoendorff, who concludes that water drinking has very little practical effect upon the uric acid excretion; and also those of Laquer, Zagari, and Pace, who found that water drinking was followed by a slight increase of uric acid excretion, but this was much less than the increase in the excretion of urea.

Minkowski's directions represent the latest views upon the regulation of water drinking in these conditions; he advises that it be so regulated as to increase the total daily amount of urine a little above the normal, i. e., to about one and one half to two litres. In general, two to three litres daily may be regarded as a sufficient quantity for the total fluids for this purpose. My own belief is that three litres is too high an allowance if, as is so often true in these cases, there is the slightest suspicion concerning the condition of the heart or blood vessels. The rational use of smaller quantities or the employment of alkaline and saline mineral waters of the Vichy or Hom-

burg, or even Wiesbaden types, will meet this indication.

As regards free flushing for the removal of calculi or gravel, etc., one should always first ascertain the condition of the circulation and then be sure that the increased intake of water is represented by an adequately greater amount of urine. Should this fail to occur, an investigation into the cause of the failure should be made before blindly ordering more water. If the necessary rise in the renal blood pressure has not been obtained, it is much better to resort to cardiac tonics with or without the alkaline diuretics.

In passing I would refer to a method of flushing, which is successfully practised by Dr. T. T. Gaunt, of this city. He puts the patients to bed and allows nothing but a goblet of cold water every hour. Although this régime is kept up for a week or longer the patients do not complain of hunger; neither do they complain of any inconvenience from the method. I believe the reason for the success of this method can be found in the fact that any possible strain upon the circulation is reduced to a minimum by putting the patient to bed.

In acute infectious diseases and in septic conditions, in which free diuresis means so much in the successful outcome, we must also guard against the dangers which may follow from crowding too much water at ordinary temperature. These patients are already on a fluid diet, and the motor and secretory functions of the stomach are lessened as a result of the fever. We can readily guard against any abuse if we carefully watch for any evidences of dilatation of the stomach. The water should always be given cold and in frequent small quantities. In septic cases where energetic and prompt results are desired I have frequently obtained good effects from resorting to the use of frequent small doses of cold alkaline mineral waters to which a weak Moselle or Rhine wine has been added.

In conclusion, I would state that the practice of simply directing the patient to drink as much water as possible, as is so often done, without considering the condition of the heart, circulation, and kidneys, cannot be too strongly condemned.

The question of the abuse of water drinking in other conditions might be considered at much greater length, but enough has been said to show how much harm may be done to the patient by the simple off-hand direction to "drink as much water as you can."

THE SURGICAL CURE OF INTRACTABLE DYSPESPIA, DEPENDING UPON GASTRIC ULCER AND ITS COMPLICATIONS.*

By WILLIAM D. HAGGARD, M. D.,

NASHVILLE, TENN.,

PROFESSOR OF GYNÆCOLOGY, MEDICAL DEPARTMENT, UNIVERSITY OF TENNESSEE; FORMERLY PROFESSOR OF GYNÆCOLOGY AND ABDOMINAL SURGERY, UNIVERSITY OF THE SOUTH.

Ulcer of the stomach, with its complications and sequences, is the most constant non-malignant lesion answerable for intractable dyspepsia. Moynihan, the great English authority upon stomach surgery, says: "It has been the immemorial custom to look upon dyspepsia as due chiefly, if not solely, to deficiency in the quantity or quality of the gastric juice, to some lack of adequate power in the stomach as a secreting organ. But dyspepsia of the intractable, constantly recurring form, is more often a matter of physics than of chemistry."

This utterance crystallizes the recently acquired surgical conception of dyspepsia and, in the correlated cure which surgery affords, adds a most welcome and important contribution to internal medicine. Intractable dyspepsia has ever been among the opprobria of therapeutics, and now to have a simple, safe, radical cure for its most inveterate forms constitutes about the most noteworthy addition of the last decade to the resources of our art.

In the light of recent experience it appears that many of our cases of obstinate dyspepsia are due to the ravages of ulcer or the relics which it leaves behind, and that the condition has to be appreciated to be properly diagnosed. The only way to recognize any important, if somewhat less frequent, pathological state is to be constantly on the alert for it. It was so with extrauterine pregnancy, with appendicitis, and with gall stones. Stomach lesions, if placed under the same scrutiny, will be as easily and frequently diagnosed. These conditions entail great suffering and incapacity and as Murphy says, they are up to this hour grossly neglected by the physician and the surgeon, with few exceptions.

Ulcer of the stomach occurs in from 2 per cent. to 5 per cent. of the population (Ewald). Fridler, in 2,200 autopsies, observed fresh or healed ulcers in 20 per cent. of women and 1½ per cent. of men. The ulcers and scars were frequently the seat of carcinomatous degeneration. Hauser believes that cancer develops in 6 per cent. of ulcers. Graham found a history of ulcer from one to fifteen years in 16 out of 18 patients operated on for cancer. Man-

sell Moullin says, when an ulcer once becomes chronic, a cure, in the full sense of the word, is seldom attained by medical treatment. Their acute course is beset by the dangers of hæmorrhage and perforation. Hæmorrhage causes death in from 3½ per cent. to 11 per cent. (Muller) of all cases. Perforation occurs in from 6.5 per cent. (Dreschfield) to 18 per cent. (Habershon) of all cases. The fatality of this catastrophe is well nigh 100 per cent.

It is, however, to the chronic ulcer and its complications that this communication has especial reference. The chronic patients are not so liable to these immediate dangers, but the constant pain is most distressing and emaciation from chronic starvation precludes the possibility of work. The dyspeptic is utterly wretched: he cannot forget his ailment: his thoughts are centred upon his stomach; his diet, his beverages; his symptoms occupy his whole attention and he has none to devote to the ordinary affairs of life. He is a pessimist and a misanthrope.

Mayo Robson enumerates the following complications of gastric ulcer:

1. Local peritonitis, or perigastritis, ending in adhesions.
2. Local peritonitis, ending in suppuration and a localized abscess.
3. Subphrenic abscess.
4. Abscess of liver, pancreas, or spleen.
5. Fistula between the stomach or pylorus and adjoining organs, or even with the surface of the body.
6. Acute perforation of the stomach wall.
7. General peritonitis.
8. Hæmatemesis and melæna.
9. Dilatation of the stomach.
10. Tumor of the stomach or pylorus.
11. Cicatricial stenosis of pylorus.
12. Hourglass stomach.
13. Spasm of pylorus producing intermittent narrowing (Reichmann's disease).
14. Atonic motor deficiency.
15. Severe gastralgia.
16. Persistent vomiting.
17. Tetany.
18. Acute or chronic pancreatitis.
19. Profound anæmia resembling the pernicious form.
20. Pressure on, or stricture of, the bile ducts, with jaundice.
21. Catarrh of gall bladder from adhesions producing attacks like those of cholelithiasis.
22. Great loss of flesh and strength, ending in phthisis.
23. Cancer secondary to ulcer—"ulcus carcinomatosum."

Seventy-five per cent. of chronic ulcers are in the pyloric region. This fact has important bearing on the later development of pyloric obstruction and upon the surgical correction of the symptoms arising therefrom. While the acute ulcer occurs most frequently in young women who are anæmic and under thirty years of age, the chronic ulcer affects those in middle and advanced life and occurs

* Presidential address before the Middle Tennessee Medical Association, at Springfield.

oftenest in men, 72 per cent. vs. 28 per cent. in women (Seymour Taylor).

The pain below the ensiform cartilage in a chlorotic female under 30 years of age, increased upon taking food, and reaching its maximum intensity about two hours after, and relieved by vomiting, which contains an excess of HCl, is significant of ulcer. If there is hæmetemesis, which occurs in 64 per cent. of cases (Leube) and melæna, the diagnosis is practically certain. There is often a fixed finger point tenderness with thickened ulcer or one that has contracted adhesions. These cases do not require the stomach tube for diagnosis.

In the chronic cases, pain and vomiting are usually present, with tenderness on pressure over the pylorus between the costal arch and ensiform cartilage. Vomitus of a fœtid character and in large quantities, is frequent, and often contains mucus, and sometimes material like coffee grounds. This is indicative simply of the presence of blood in the stomach and other means must be resorted to to discriminate ulcer from cancer. These symptoms are often in abeyance for weeks and even years. The presence of the ulcer may be unexpectedly declared by the occasional advent of serious hæmorrhage or perforation.

Most of the symptoms, however, are from some of the complications; the contraction of a pyloric ulcer in healing causing obstruction with dilated stomach, or the presence of perigastric adhesions; and, where dilatation is present, the prolonged retention of food is evident by the rejection of food in the morning that was taken the night before. Loss of weight is almost constant and may be extreme. Pyloric tumor from induration, or adhesions may be present, and suggest the tumor of malignancy. The induration may be so suspicious in its mimicry of cancer that it is not extravagant to say that many patients with chronic ulcer have been mistaken for sufferers from cancer and allowed to die, that might have been saved by accurate diagnosis and prompt operation. Chronic ulcer is usually smooth; cancer nodulated, rough, and uneven.

Next to the pylorus the posterior wall of the stomach is the most frequent site for ulcer, and in this location, the pain, instead of being in front, is under the left scapula or at the head of the ninth and tenth ribs. Lying on the back increases the pain, which is relieved by standing, leaning forward, or lying on the abdomen.

The most characteristic features of gastric ulcer are its persistence and recurrence. In spite of the most careful dietary supervision, rest, and even rectal alimentation, as soon as solid diet is resumed, the former symptoms of pain, vomiting, and bleeding again assert themselves. This may be repeated

over and over again. The probable explanation is that the ulcer, which often attains considerable size, may contract attachments to adjacent structures, especially if, as is very frequent, it happens to be upon the posterior wall and adherent to the pancreas. It may be likened to an old leg ulcer that has become attached to the periosteum covering the tibia. Contraction is impossible and cicatrization is interfered with every time the patient walks.

Hæmorrhage from a chronic ulcer is a different thing from hæmorrhage in an acute ulcer. In the latter the hæmorrhage, while sharp, does not invariably tend to recurrence and the patient quickly recovers from the temporary depression. In chronic ulcer, the hæmorrhage, though small in amount, recurs with brief intermissions of a few hours or days, and the frequent repetition produces a condition of most profound anæmia.

It is not regarded as good surgery to operate for hæmorrhage in acute ulcer, because the oozing seems to come from numerous erosions and not from any vessel. It is manifest that operation would be unavailing in that form of hæmorrhage. In the other form of ulcer, the base is hard and infiltrated, and the edges evidence the long standing of the disease; the eroded vessel is unable to contract and retract in the indurated and thickened tissue, and therefore spontaneous closure is unlikely. Young patients, the subject of acute round ulcer, rarely have fatal hæmorrhage. It is stated by Hood that no death from hæmorrhage in a young female with gastric ulcer occurred in Guy's Hospital in twenty years.

Operation in the chronic ulcer can easily determine its site on account of the induration; the ulcer can be excised or its base ligated; a quickly performed gastroenterostomy seems to be competent to cure the condition.

Cases of a very severe single hæmorrhage might be subjected to operation before recurrence, provided the hæmoglobin is or can be brought above 35 per cent. When the hæmorrhage occurs frequently, and when there is soreness, operation is indicated. In the acute cases, the operative mortality of nearly 40 per cent. is almost prohibitive.

The question of perforation is important and interesting. Perforation of the chronic gastric ulcer takes place with varying frequency. The lowest estimate of its incidence is 3.2 per cent.; the highest statistic ratio, that of Fenwick, is 28.5 per cent., while Robson calculates that from 15 per cent. to 20 per cent. perforate. It therefore occurs with sufficient frequency to demand that any sudden, severe, stabbing, and altogether unbearable pain in the epigastrium followed by collapse, become the subject of the closest scrutiny. The anxious, agonized

facies, the cold, clammy perspiration, livid lips, and blanched features tell too plainly the havoc that is being wrought on the interior. The abdomen, which is at first rigid and retracted, soon becomes distended by the consecutive peritonitis which seals the doom of the victim in 96 per cent. of these so called hopeless cases. But are they hopeless? Mikulicz was able to find only one case that was saved, out of 35 operations between 1885 and 1893, but between 1894 and 1896 there were 68 operations, with 36 deaths, or a recovery of 47.06 per cent.

Prompt operative interference should be made in these cases. If operation is done in the first twelve hours, 81.5 per cent. of the patients will get well; in the second twelve hours, 36.4 per cent. survive, and in the third twelve hours, only 12.5 per cent. If the subjects live over forty-eight hours, then about half of them can be saved. (Adapted from Mayo Robson.)

The appalling fact that the dangerous complications of hæmorrhage and perforation are attended with such high mortality, with or without operation, constitutes the most eloquent plea possible for a surgical cure of all chronic ulcers before these disastrous sequences supervene. All cases that have resisted careful medical and dietetic treatment demand operation.

Ulcer is a surgical disease like appendicitis, but has much less chance of recovery. One writer compares it to ulcer of the rectum, of the tongue, and of the lower extremity in the necessity for surgical treatment. Ticomi takes the advanced position that it should uniformly receive radical treatment, which he believes to be as necessary as the radical treatment of hernia. While I cannot endorse this, believing as I do that the majority are medical from first to last, yet I agree with von Leube, the most ardent advocate of purely medical management, when he says "if a gastric ulcer is not cured in four weeks' treatment it cannot be cured by medical treatment at all."

We must not ignore the mortality of gastric ulcer, which Heydenreich puts at 25 per cent. and Einhorn estimates as directly and indirectly the cause of death in 50 per cent. Contrast that mortality with the optimistic statement of Wyllis Andrews, that the surgical treatment of gastric ulcer should and will yield ultimately as good results as the interval operation for appendicitis.

Greenough and Joslin say that out of every two patients seen in a hospital with gastric ulcer, one will ultimately die. Contrast that gloomy outlook with the report of Moynihan: 100 gastroenterostomies for gastric ulcer with only two deaths.

Even when gastric ulcer heals, the frequency of its location at or near the pylorus begets in many instances, as a result of the cicatrization, a stenosing

obstruction that often results in a dilated stomach. In 1902, out of 252 routine stomach tests, Graham found 135 cases of dilatation of the stomach due to pyloric ulcer and cancer. When the ulcer, in its next most frequent site the posterior wall, cicatrizes it often produces a mesial contraction that results in the hour glass stomach. In some instances a trifid stomach is formed.

In any location an ulcer is prone to necrose deeply and, as the result of infection, to produce adhesions in adjacent viscera. Perigastric adhesions are especially vicious when they occur around the pylorus, acting from without as an obstructive agent and inducing a train of symptoms that is a type of the mechanical form of dyspepsia, not amenable to medicinal cure, but requiring surgical relief. I have seen adhesions about the pylorus from a recent cholecystitis produce such obstruction as to cause vomiting of all ingesta and the patients had to be nourished per rectum until relieved by operation.

The frequent occurrence of gastralgia for a long period, in cases where an investigation of the gastric functions fails to detect any abnormality, should lead to suspicion of adhesions.

The history of these dilatation cases extends usually over many years, probably. Pain, vomiting, and perhaps hæmorrhage, exacerbations, and remissions are conspicuous. Finally the infrequent vomiting assumes the enormous quantity indicative of retention and stagnation.

The routine examination of stomach cases very easily demonstrates the presence of dilated stomach. When the tube is introduced and removes the test meal, the patient having been requested to lie down, the stomach is pumped full of air with a Davidson syringe. Its outlines are then easily discerned by inspection, percussion, and auscultatory percussion. Occasionally a tumor is thus developed near the pylorus which may be a high lying pyloric ulcer greatly indurated. Dilatation with pyloric tumor, of course always raises the suspicion of cancer, but the chemical examination in cases of ulcer will usually show an excess of HCl, whereas in cancer there is generally an absence of HCl, with the presence, however, of lactic acid.

I shall not go minutely into the important and sometimes difficult differentiation of cancer of the stomach, but referring again to non-malignant dilatation, the splashing sounds can be demonstrated and the causative pyloric obstruction is often confirmed by actually seeing the left to right peristalsis.

These are the mechanical conditions resulting from chronic ulcer and its complications, which produce the invalidism and utter misery of the dyspeptic whose sufferings are too often regarded as chemical or due to motor insufficiency, and whose emaciation, from the chronic starvation of regur-

gitated food, is sometimes looked upon as a part of the cachexia of cancer. Indeed many cases of this character with tumor have, even after exploration, been diagnosed as malignant, until, as the result of the gastroenterostomy that was done as a palliative resort, the patient's ulcer was cured and he got entirely and permanently well. In the treatment of most cases of chronic and incorrigible dyspepsia, depending upon the existence of chronic gastric ulcer and its complications, gastroenterostomy has demonstrated its competency to cure.

The explanation of these cures lies in the rapid emptying of the stomach and the resulting physiological rest which allows the ulcer, frequently more than one, to heal. The stomach is simply a hopper for food, and in order to drain it, which is the object in all cases of ulceration, the most dependent point must be chosen.

The anastomosis of the jejunum is usually made either anteriorly (the method of Wolfler) or retrocolic (the method of von Hacker). Much discussion has arisen as to which is the preferable method, but the Mayos, who have had the largest experience in gastric surgery in America, after employing both methods, have found their results to be equally good with either. They demonstrated, however, and established the principle that in either operation the desideratum was to make the opening at the lowest part. When this was done, the difference between the anterior and posterior openings was actually found not to be half an inch.

The discussion as to whether the Murphy button or simple suture should be used is not momentous. The results with each have been very satisfactory. The button is simpler for the operator who is not dexterous with the suture. It requires a shorter time, although some operators employ the suture with great speed. Moynihan commonly completes the entire operation in thirty minutes, and has performed it in seventeen minutes. The tendency seems to be toward the simplification of all surgery and the discarding of all mechanical aids to gastrointestinal anastomoses.

In the performance of stomach operations great care should be exercised in the preparation of the patient. His nutrition should be improved by rest in bed, rectal alimentation, and measures conducive to increased metabolism. The mouth should be sterilized and all carious teeth extracted. Stomach lavage is a necessity to alleviate the stagnation of retention. The last lavage should be some hours before operation and all fluids should be evacuated by putting the patient in Trendelenburg's position, if necessary. A neglect of this precaution has caused drowning of patients from the large quantities of fluids ejected during anesthesia.

The following technique of gastroenterostomy, as

observed in the practice of the Mayos, has been the simplest and altogether the most ideal method that I have employed. A three and a half inch incision through the right rectus muscle gives ample space for careful exploration of the stomach and adjacent viscera. The finger determines the patency of the pylorus, which should allow the finger and thumb to meet easily. Often the indurated ulcer can be felt as a hard, thickened area, or seen as a puckered spot through the peritonæum. Frequently where the ulcer cannot be felt, there are "sentinel glands" at the greater curvature that indicate its presence. The posterior method utilizes the jejunum just as it lies normally against the stomach with the mesocolon intervening. In the operation, this is nicked and, with careful avoidance of the middle colic artery, torn more widely. The omentum and colon have been turned up over the stomach. The posterior wall is pushed through the mesocolon aperture and a suitable point selected near the greater curvature and about its centre. A fold, 3 inches long, is grasped in a Doyen forceps. The jejunum is picked up at the plica jejunoduodenalis, and at a point about 3 or 4 inches therefrom (Mikulicz) it is also grasped in forceps. The remainder of the stomach, omentum, and viscera are returned to the cavity and nothing is visible but the two forceps holding the viscera and carefully surrounded with gauze, to be anastomosed outside of the abdomen.

The jejunum is sewn transversely to the stomach for a distance of 2 inches by a continuous seroserosure suture of Pagenstecher linen. The viscera are then opened and an ellipse of mucosa is excised from each, to give a larger and an unobstructed calibre to the anastomotic ring. A second over and over suture now unites all coats of the cut margins of each viscus and is continued around in front, completing the union of the inner circle. The clamps are removed. The first suture is then resumed through the serosa, around the inner line until it meets the point of first introduction, where it is tied and completes the anastomosis.

The inner suture, going through all the coats, is hæmostatic, and the outer, which includes only the serous and subserous, protecting and approximating.

The mechanics of this procedure depends upon the fact that the short limb of the jejunum goes straight from its junction with the duodenum to the anastomosis. It has no slack to drag upon its new attachment. The transverse union of the jejunum does away with the loop which has always bred mischief. A similar operation is used by Czerny, and Peterson says there has been no case of vicious circle in 215 operations by this method. I shall, therefore, not describe the various ingenious but, according to this, unnecessary procedures to over-

come that hitherto troublesome and fatal complication.

Immediate improvement is the rule and continues and becomes permanent in the great majority of cases. Emaciation disappears, the dyspepsia vanishes, and the patient can take solid food with ease, which to the former sufferer is almost unbelievable.

I shall not go into the various other operative procedures applicable to gastric ulcer and its consequences, as drainage is the essential, and gastroenterostomy may be taken as the type.

It may be concluded, therefore, in this new and important field of surgical usefulness, that the hitherto neglected and distressing cases of otherwise incurable dyspepsia have a reasonably certain and safe assurance of restoration to function and happiness by modern gastroenterostomy and allied operations.

THE PATHOLOGY AND TREATMENT OF DIABETIC GANGRENE OF THE LOWER EXTREMITY.*

By HORACE J. WHITACRE, B. S., M. D.,

CINCINNATI, O.

Gangrene in the lower extremity is a symptom of grave significance, which is often presented to us as the first evidence of serious and incurable disease. It may occur in this region as a result of a variety of conditions. This variety in causative factor has led to the classifications of a senile type of gangrene; diabetic gangrene; the gangrene of frostbite; symmetrical gangrene; gangrene from embolism, thrombosis, or injury to the main arteries; a gangrene caused by bacterial infection (streptococcus, *Bacillus aerogenes capsulatus*, and bacillus of malignant oedema), and others. The present paper will deal mainly with diabetic gangrene, incidentally with the senile type, and will be devoted to a report of nine cases with conclusions.

CASE I.—The record of this case is incomplete, inasmuch as very meagre notes were preserved, yet it will serve a purpose. The patient, male, fifty-two years of age, unmarried, Englishman, waiter, presented himself for treatment, suffering from an infected corn which had become gangrenous. An area of gangrene the size of a twenty-five cent piece was found on the inner side of the left foot over the metatarsophalangeal joint. This was surrounded by a wide area of inflammatory reddening and swelling. The urine contained sugar, yet he had suffered no symptoms previous to the gangrene which caused him to consult a physician, and did not know that he had diabetes. He was a liberal drinker, had been

a waiter for years, and had always enjoyed good health. Two days after admittance to the hospital the second toe became gangrenous. Within three days the third and fourth toes also became discolored and a dusky zone appeared on the dorsum of the foot. The temperature was moderately elevated throughout. A Syme's amputation was made as a conservative operation. The vessels were found to be obliterated, yet the surface of the wound bled freely and the operation was completed. The flaps were sutured. On the third day gangrene appeared in a large part of the posterior flap. A circular amputation was then done through the lower part of the thigh. The artery at this point was decidedly atheromatous. The flaps, as well as the fascial planes, again sloughed in large part, as did also the surface of the wound. The stump was now dressed open, general treatment was directed to the diabetic condition, and the sloughs were allowed to separate. The patient made a slow recovery. His stump healed after the opening of numerous abscess tracts, which had formed along fascial planes, the sugar disappeared from the urine, and the man was discharged from the hospital in a very satisfactory condition. He was well six months after the operation, when he passed from observation.

CASE II.—A Polish Jew, thirty-five years of age, and a pedler, gave a history of having suffered most intense pain in the toes of both feet for about three months. He was certain that he had not frozen his feet during the winter which had just closed. He had been treated in the out patient clinics for this pain without relief, and was sent to the hospital because of a gangrene in the third and fourth toes. The patient was not well nourished, but seemed to be in good health, with the exception of his feet. Sugar was found in the urine, but he presented none of the constitutional symptoms of this disease. The arteries could not be felt at the ankle. Amputation was decided upon, but it was deemed wise to expose the anterior tibial artery in the upper third of the leg before deciding upon a site for amputation. This artery was found to be completely occluded, and amputation was done above the knee. The patient made a satisfactory recovery, and was discharged with no sugar in the urine.

A dissection was made of the arteries below the knee. The anterior tibial artery was completely obliterated. The posterior tibial was obliterated below the middle third, while the upper two thirds still retained a very narrow lumen.

CASE III.—Mrs. M., sixty-two years of age, a woman of slight build and minimum adipose tissue, was sent to me from Rising Sun, Indiana, with gangrene of the second and third toes of the right foot. This gangrene had appeared after a slight injury to the middle toe. The patient had always enjoyed good health and did not know that she suffered from diabetes until her physician, Dr. O. P. M. Ford, found sugar in her urine, when consulted relative to the gangrene. When she entered the hospital the gangrene was confined to the toes and an expectant line of treatment was applied. The patient was kept in bed

* Read at the meeting of the Mississippi Valley Medical Association at Memphis, Tenn., 1903.

and the foot was rendered first aseptic, then perfectly dry; hot water bottles were placed alongside the foot and the entire extremity was slightly elevated. An antidiabetic diet was given. The urine contained three per cent. of sugar. Gangrene appeared in the fourth toe and within seventy-two hours had extended to the dorsum of the foot. Amputation was advised. I was prevailed upon, against my better judgment, to attempt an amputation in the middle of the leg. At the time of this amputation the arteries were found to be almost occluded, yet hæmorrhage was free and the amputation was completed. The patient recovered well from this operation, but the flaps became discolored on the fourth day and were extensively gangrenous on the seventh. The temperature became elevated with this change. An amputation above the knee was very rapidly made seven days after the first operation. The patient never became satisfactorily conscious after this second operation. The wound showed no evidence of slough, but the patient became progressively more difficult to arouse and to feed, and died, six days after her second operation, in profound coma.

I believe that in this case a primary amputation above the knee would have resulted in the recovery of the patient. A study of the arteries of the leg demonstrated a complete obliteration of their lumen below the upper third. The popliteal artery was greatly narrowed and sclerotic, while the femoral at the site of division was rigid and presented atheromatous patches.

CASE IV.—Mr. H., sixty-two years old, manufacturer of ladies' hats, married, of Jewish extraction, of temperate habits, had enjoyed good health up to the time of the present illness. This illness began with an injury inflicted in the close paring of a corn in the sole of the left foot. Seven days after this injury the adjacent skin became sensitive to the touch and reddened. An area of gangrene three fourths of an inch in diameter then appeared at the base of the middle toe. Dr. W. H. DeWitt, the family physician, was called at this stage. His examination revealed the following facts: The patient, a fleshy man, had been in the best of health and had not consulted a doctor for years. He had not lost flesh recently. Appetite good (not voracious), bowels regular. The urine had been passed in the usual amounts and seemed to the patient to be normal. There were, in fact, no subjective symptoms. The urine was found to contain a high percentage of sugar and no albumin. The treatment instituted was as follows: The patient was confined to the house and urged to keep the foot elevated as much of the time as possible; a strict diet was enforced; and arsenic was given internally.

The small slough separated after a few days, leaving a deep undermining cavity with sloughing base and walls. There was no extension of the gangrene superficially, but the deeper tissues did not show the slightest granulation; indeed, the purulent discharge increased and the process seemed to be extending upward along the tendon

of the middle toe. This cavity was cleansed daily with hydrogen peroxide or dry cotton swabs and dressed with a ten per cent. balsam of Peru application. The temperature varied from normal to 99.5° F. The urine still contained three and one half per cent. of sugar after the diet had been well established.

Nine weeks after the appearance of the primary spot of gangrene I was asked by Dr. DeWitt to see the patient, because of imminent gangrene of the middle toe. The patient was now put to bed. Every effort was made to render the foot aseptic and to mummify the gangrenous toe by dry powder dressings. The foot was enveloped in a voluminous cotton covering, placed between hot water bottles, and elevated about six inches. The internal medication was continued and the patient urged to drink at least one gallon of distilled water per day. He exceeded this amount after the second day.

The pain that he had suffered seemed to be entirely relieved by the elevated position of the foot. A line of demarcation formed promptly and the gangrenous toe was disarticulated at the end of six days, without hæmorrhage. The infectious process in the sole of the foot did not progress so favorably. More pus was discharged, the probe could be inserted upward for two inches and a half to three inches, and the temperature reached 102° F. Coincident with this extension of the infectious process there appeared a ring of hæmorrhagic bleb, and under this a band of gangrene which almost completely encircled the base of the great toe. The entire toe then became insensitive, cold, and purple. The temperature now reached 103° F. Three days after gangrene had appeared in the great toe a zone of dusky discoloration and hæmorrhage bleb formed on the dorsum of the foot. Permission to operate was granted and the patient was sent to the Jewish Hospital.

Operation under chloroform. A tourniquet was not applied. The leg was raised high in the air and an attempt made to amputate at the knee, leaving the cartilages. The popliteal artery was found to be practically closed, however, and the amputation was made at the middle of the thigh. Even at this location the artery was found to be extensively calcareous and rigid, yet there was no reason to think that the artery would be found to be in better condition three, four, or even five inches higher up, and a heavy ligature was carefully applied. The wound was not sutured, its edges being held in place by gauze dressings. The patient endured the double operation well, and showed no evidence of shock. A tourniquet was loosely wrapped around the thigh, above the dressings, and allowed to remain here for two weeks, for immediate use in case of secondary hæmorrhage. Three days after operation the entire circumference of the skin flap was found to be gangrenous for a varying zone, as was also the entire surface of the wound. The bone protruded from the retracted tissues. The temperature remained practically normal, except for one rise to 100.2° F. for three hours. The total amount of urine passed in twenty-four hours varied from 1500 c.c. to 1780 c.c. This urine contained ten per

cent. of sugar. The patient was extremely restless or delirious.

This picture presented was certainly dismal. The stump was maintained in a perfectly aseptic condition and the surface of the wound sprinkled with digesting powder, to dissolve the necrotic tissues. In the course of three weeks the stump presented a perfectly healthy granulating surface, the mind was much clearer, the appetite good, and the sugar had gradually declined to three per cent. One week after the amputation a gangrenous spot, the size of a silver dollar, was found over the right heel. This was unquestionably a decubitus slough. This leg was at once suspended in an improvised hammock and there was not the slightest extension of the slough.

For four weeks after the operation this patient presented the most unusual symptoms. He recognized his family and his attendants and would respond rationally to the first few questions propounded, but for the remainder of the time he was delirious to a degree that disturbed the entire hospital. His nights were hideous to himself and to his nurses; indeed he required the constant attention of an able bodied male nurse to restrain him. After the trial of morphine, chloral, codeine, bromides, and trional, without results, hyoscine hydrobromide, $\frac{1}{100}$ grain, relieved the delirium and gave him sleep.

After the third week the improvement in both local and general conditions was entirely satisfactory. The temperature was normal, the appetite good, the urine was passed in normal amount and contained two per cent. of sugar; the wound presented a perfectly healthy granulating surface and the patient was able to sit up for a great part of the day. The stump will be completely healed in another fortnight. The sugar has entirely disappeared from his urine.¹

CASE V.—J. E., forty-three years old, German, male, married, night watchman, had suffered from varicose veins of the leg for a long time. He had otherwise enjoyed fair health until a few weeks before, when he began to lose flesh and strength, even though his appetite was very good, indeed voracious. He had been drinking large amounts of water. In January, 1903, he bruised his right great toe. This injury left a dark red area of congestion on the inner half of the tip of the toe, and he was led to call his family physician, Dr. A. G. Kreidler, by reason of the fact that this bruise had become larger, instead of smaller, during a week of home treatment. Dr. Kreidler found a well marked area of gangrene on the tip of the toe, a circular area of gangrene over the site of a bunion on the metatarsophalangeal articulation, and demonstrated five per cent. of sugar in the urine. I was asked to see the patient at once and recommended the same line of expectant treatment that has already been detailed—diet, aseptic mummification, elevation, and dry heat. He was also given codeine and a preparation of arsenic internally. In one week the general condition of the patient had greatly improved, the sugar percent-

age had decreased one half, and the gangrenous process was arrested. Three weeks later the sugar had disappeared from the urine, the gangrenous sloughs had separated, the wounds were about healed, and the general health was excellent.

This patient remained on the diet and resumed his duties as a night watchman. He has again consulted Dr. Kreidler within the past few days, relative to a similar area of congestion on the opposite foot, with the statement that his diet list became so insufficient that he had been forced to eat other things. The urine was again found to contain a high percentage of sugar. He has been placed under rigid dietetic, medicinal, and local treatment, with very favorable results, and there is fair reason to believe that he will again recover from the threatened gangrene.

Pulsation could not be felt in the posterior tibial or the dorsalis pedis arteries at the time of my examination, but I am informed by Dr. Kreidler that pulsation returned in about two weeks after the onset of the gangrene. The radial and the temporal arteries show undoubted signs of arteriosclerosis.

CASE VI.—Mr. S., seventy-six years old, German, retired merchant, had always enjoyed excellent health, and had led an active life. After slight injury he developed an area of discoloration about half an inch in diameter, on the inner half of the tip of the great toe. This formed a blood blister, which gradually increased in size, and Dr. J. C. Buttemiller was called. The gangrene continued to extend until the inner half of the great toe became involved as far as its base. A second circular area of gangrene appeared two days later in an old bunion on the inner side of the metatarsophalangeal articulation, and attained the size of a twenty-five cent piece. In addition to this spot the dorsum of the foot became much reddened and a small blister formed. Sugar was not found in the urine of this patient. The expectant line of treatment, which has already been outlined, was applied to this case with most gratifying results. The gangrene was arrested, the sloughs separated promptly, and the patient recovered.

CASE VII.—Mrs. K., sixty-eight years of age, had suffered greatly with corns in the soles of the feet. Many chiropodists and several physicians had been employed from time to time to treat this condition. In August, 1903, she was treated by a careless chiropodist, who infected the corn. He continued to pare the same and other corns with the knife that he used to clean up the ulcer, and the foot became inflamed. On September 10th, the second toe of this foot became insensitive and turned purple, then black. Dr. J. C. Buttemiller was called at this stage and I saw the case in consultation a few hours later. The entire second toe was black, yet a line of demarcation had formed. An area of inflammatory redness extended to the ankle on the dorsum. The sole of the foot was covered by a thick, horny callus, in the centre of which there was a deep unhealthy ulcer from which an ichorous pus was discharged. There was much pain in the foot. The tempera-

¹Three weeks after paper was read: The wound has almost healed, patient has been on a regular diet for three weeks, with no recurrence of the sugar in the urine, and the general health is excellent.

ture was 100° F. The urine was loaded with sugar. The general condition was good. A wet dressing of aluminum acetate was applied, to reduce the inflammation and the foot was elevated. The patient was asked to drink at least one gallon of water daily, and was given acetanilid 7½ grains and sodium bicarbonate 15 grains three times a day, as internal medication. On the following day the redness had become greatly reduced and the dry treatment was instituted. Local conditions now remained about stationary for three days, but the temperature became higher and ranged from 100° to 103° F. Five days after I first saw the patient, and nine days after the beginning of the gangrene in the toe, a dusky discoloration and a hæmorrhagic bleb formed on the dorsum of the foot, at the base of the gangrenous toe. Amputation was urged and granted. The patient was removed to the Jewish Hospital and a circular amputation made in the lower third of the thigh. This was done with the leg high in the air and without tourniquet. The femoral artery was much narrowed by an endarteritis obliterans at the seat of ligature. The tissues were so lax that two catgut sutures were applied to the deep tissue, and two silkworm gut sutures to the skin. Otherwise, the tissues were held together by the dressings. The patient stood the operation perfectly well and required no stimulation. Hot salt solution was given per rectum every three hours, in order to supply her tissues with abundant water. Her condition remained fairly good for four days, but she slept most of the time. On the fourth day she took her food less readily, her mental condition was less satisfactory, and both her pulse and respiration became very rapid. She died five days after operation. The arteries in the amputated leg showed the same advanced changes that have been found in preceding cases. Both arteries were totally obliterated at the ankle. The posterior tibial at its middle had narrowed to a diameter of one eighth inch, and this lumen was filled by a recent blood clot. The popliteal artery was much narrowed, but still open. The lumen of the femoral artery formed a triangle at the seat of ligature.

CASE VIII.—Consists only in the report of the findings in a popliteal artery which was removed from a case of diabetic gangrene operated on by Dr. N. P. Dandridge. This artery shows the same marked degeneration of the intima that has already been reported in other cases. This artery presents the same degree of change that has been associated with total obliteration of the branches at the ankle in other cases. While much conclusion is not justified the specimen will serve as additional evidence.

CASE IX.—A negro, thirty-two years of age, presented himself at the Cincinnati Hospital, with a well developed gangrene of the leg. No history of any value could be obtained from him. An amputation was made by Dr. N. P. Dandridge at the junction of the lower and middle third of the thigh. The patient recovered promptly. The femoral artery was very greatly narrowed in this case and the entire popliteal artery was totally

occluded by the organized tissue of an obliterating endarteritis. The popliteal vein contained a recent thrombus. This case is included in the present report because of the age of the patient and the interest that attaches to the arterial change. The endarteritis was probably of syphilitic origin in this case.

(To be concluded.)

ON RUBIDIUM SALTS, WITH SPECIAL REFERENCE TO THE USE OF RUBIDIUM IODIDE IN OPTIC ATROPHY.

By PAUL BARTHOLOW, M. D.,
NEW YORK.

Comparatively little attention has been paid to the interesting subject of the uses and effects of the rubidium compounds. What literature there is will be found in many ways insufficient. At best it appears to be tentative, the chief essays in this field being devoted to the object of tracing analogies between this rather rare element and the other members of the same series, such as potassium (principally), cæsium, sodium, beryllium, etc. With potassium, rubidium stands in such close relation, with respect to physical and chemical properties, the behavior of both to reagents being exactly similar, that the discovery of their separate existence might have been deferred indefinitely but for spectrum analysis (1). The spectroscope, in fact, revealed the new prodigy to Bunsen and Kirchhoff in the mineral waters of Creuznach and Durckheim, the element showing itself by two characteristic red absorption bands in the extreme red portion of the spectrum (2). Rubidium is univalent, belongs to the alkaline group of metals, and appears in the pure state as a silvery substance, of very slight density. Its specific gravity was found to be 1.50, and quite recently its combining weight has been fixed at 85.4 (3). It is a fugitive substance, when isolated; volatilizing readily, and igniting spontaneously in moist air. In nature it is widely diffused, though never in great quantities (4). Bunsen extracted it from lepidolite; and it is also found in the ashes of many plants, in the crude potash obtained from the residue of beet sugar manufacture, and in tobacco leaves, coffee, tea, and cocoa (5). Rubidium appears to be useful to the building up of plants, though in what way is not definitely known; for the vegetable organism has the power of assimilating it in association with sodium and potassium. Whether it plays any part in the organization of human structures is at present a matter of pure speculation (6).

In the view taken of the rubidium compounds by physiologists, the most prominent place has

been occupied by the chloride. In general, as may be deduced from the researches of Richet (7), Botkin (8), Brunton and Cash (9), Harnack and Dietrich (10), this salt possesses properties, and exerts effects, similar to those of potassium chloride, but distinctly less powerful. For example, Grandaue found that an injection into the jugular vein of a rabbit or dog of one gramme of rubidium chloride in 15 grammes of water produced no obvious disturbance (11). On the other hand, such an injection of potassium chloride in these animals caused death within a few minutes. It is generally inferred, and the inference is true as regards any ordinary dose, that rubidium chloride is scarcely one half as toxic as potassium chloride. Under artificial conditions, however, where the dose is very large and the resistant mass very small, e. g., in frogs or turtles, effects that are, probably speaking, toxic have been observed. Under such conditions, first a stimulant, and then, with increasing doses, a paralyzing action on the heart have been noted, an action compared to that of digitalis or barium. Such resemblance would seem to be figurative, for Brunton and Cash observed that the barium salts were antagonistic to rubidium. With respect to their practical utility, it cannot be said that researches into the effects of rubidium chloride in such animals as the frog, the rabbit, and the guinea pig, are very satisfactory, for little more can certainly be deduced from them than that, in sufficient doses, intravenous injections cause a progressive enfeeblement of the heart, and arrest it, though not invariably, in systole. In practice, it must be remembered, as Professor Naunyn (12) pointed out, that neither rubidium nor potassium is toxic when given medicinally, or by the mouth, in man; and universally this fact goes a great way towards a settlement of the question. In one particular, as regards the action of rubidium chloride on animals, opinions are contemporaneous that it paralyzes striated muscle fibres. Clinically, with respect to the iodide or bromide, I have not observed that they have any effects that can be separated from the probable effects of iodine or bromine ions, freed by the dissociative force of an aqueous solution; and, as these salts, iodide and bromide, form a reaction with the sodium chloride of the blood, it would seem probable that the rubidium chloride thus coming into existence in the organism does not, at least in the conditions of practice, exert any distinct effect on muscle tissue, or in particular on cardiac muscle.

That rubidium salts are not in any sense heart poisons is the opinion of Leistikow after extensive experience (13). Upon the motor nerves

rubidium chloride has little action, but not improbably, as many investigations imply, it may, in very large, overwhelming doses, depress the heart by stimulating the vagus and higher inhibitory centres. In medicinal doses, this and the other rubidium salts are supposed by most to support the heart and raise slightly the arterial tension (14).

From this general review of the rubidium salts, let us turn to a brief examination of the effects of rubidium iodide in practice. So far it has been used chiefly in syphilis, as a substitute for potassium iodide, in individuals who were intolerant of the latter, or in whom its prolonged use had caused iodism, or, again, in those who had heart disease. Employed in this way, the benefits of rubidium iodide are asserted without qualification by a number of the best authorities, as, for example, Neisser (15), Jadassohn (16), Leistikow (17), Wolff (18), Schöler (19), v. Mering (20), Jacobson (21), Vogt (22), and Braunschweig (23), who are all, I think, that have published their views of its medicinal properties. It is principally of service in the skin and visceral phenomena of syphilis. Leistikow also reports a case of acute polyarthritis of gonorrhoeal origin in which rubidium iodide effected a cure. There can be little doubt in the mind of any one who has read these reports, or who has made trial of the salt, that it is less irritating than potassium, affects the stomach less, that with even less probability can it be thought likely to cause violent catarrh of mucous membranes, muscular weakness, or the graver oedema of the glottis. Without intending a panegyric on a useful remedy, I believe that the soundness of these deductions seems scarcely open to objection.

Some less obvious properties, which I thought could be traced in the physical nature of rubidium iodide, and which I endeavored to ascertain by some investigations, led me to consider that it would be of value in cases where very delicate structures were diseased, and where, on account of their anatomical situation, it was a matter of great difficulty to reach the morbid process—in atrophy of the optic nerve. These properties are: (a) The non-irritating character of a five per cent. solution; (b) its great diffusibility; (c) the power, which this solution has of drawing water from the circulation and causing a vigorous movement of red blood corpuscles to the site of application; (d) the chemical activity of the ions of rubidium and iodine freed by the dissociative force of the aqueous solution. In addition, we may postulate two things—that it is the "free ions only that react," that it is the iodine ion more

than the rubidium ion whose maximum effects we desire to attain. It is known that electrolytic dissociation goes on freely in solutions of the iodides of the alkaline group and that their action is proportional to their dissociation. In solution, rubidium iodide splits up more rapidly than the other iodides; the ratio was determined by Erdmann as follows (24):

Lithium iodide.....	107.4;
Sodium iodide.....	119.1;
Potassium iodide.....	140.
Rubidium iodide.....	144.3.

From these observations, it would appear (25) that rubidium iodide might be the most active agent of the group.

To such theoretical considerations it may be added that rubidium iodide has been recommended in a general way in the treatment of eye diseases by Bunge (26). Three or four drops of the following solution are instilled:

Rubidium iodide.....	25 grains;
Distilled water.....	1 ounce.

For some time I have used this solution, which is limpid, non-irritating, and painless, in the case of a patient who has suffered for years from tabes, and in whom troublesome symptoms of optic atrophy have been superadded, e. g., concentric diminution of the field, with progressive loss of acuity of vision. As the history showed, these symptoms were in all probability caused by the action of a postsyphilitic toxine. The eye trouble seemed to have antedated the tabes, and to have shown itself by a sudden attack of hemianopsia. On direct examination by daylight, the discs presented an appearance of extreme pallor, indicating a degeneration of nerve substance and growth of connective tissue. The calibre of the vessels was narrowed. The light reflex of the iris was lost. The patient was a man of 55 years of age, of neurotic heredity, and it was interesting to note that the signs of an original neurasthenia interpenetrated the tabetic phenomena, especially the ataxia. Under observation of strange or curious eyes, the incoordination was strikingly increased. The general condition was remarkably good, and the heart and kidneys were normal. The vexations that followed as a consequence of failing vision induced the patient willingly to try the most energetic measures. We employed by turns injections of mercuric chloride, of iodipin, of strychnine into the temporal region to the limit of safety, but without arresting but in a temporary manner the deterioration of sight. Beginning August last, the instillation of rubidium iodide has been pursued methodically, with short intervals of cessation. For three

weeks no improvement was discernible. At the end of five it began to be evident that he could use his eyes more effectively, from his manner of walking, advancing towards an object, etc. The outlines of objects became a trifle more defined, and the patient himself voluntarily admitted that he "saw better." Owing to the badness of vision, the test types were of little avail, but from rough tests it appeared November 1st that the area of sight had enlarged sufficiently to make the fact certain.

It is useful to ask how far this improvement might justly be ascribed to the remedy, how far to one of those sudden changes for the better to be observed in this malady. Upon a skeptical appraisal of the two factors, it seems to me that the improvement was more distinct and lasted longer than one of the periodic gains occurring at intervals in the long course of the disease, and that the remedy is entitled to some credit. As a means that promises some accomplishment in cases so unfavorable, it is worthy of attention.

157 WEST FORTY-SEVENTH STREET.

Dr. Leonidas H. Laidley has resigned his position as medical director of the World's Fair at St. Louis.

THE PRESENT STATUS OF RAILWAY EMERGENCY WORK.

By U. F. MARTIN, M. D.,

NEW YORK.

(Concluded from page 57.)

FIRST AID INSTRUCTION.

Turning to the question whether employees shall be instructed as to how these packages may be utilized we again find diametrically opposed opinions. There are men, who opposed the first aid package, who here agree as to the advisability of giving some instruction to the men. There are others who oppose both schemes, relying upon the surgical aid that can be obtained in the vicinity. As to how much and in what way this knowledge shall be imparted to the men, there is also considerable difference of opinion. A glance at the tabulated answers will show this. Speaking favorably of such teaching, the employees of the Grand Trunk Railway in Toronto and vicinity have had the benefit of similar instruction by Dr. Bruce L. Riordan for many years past, and a large number of classes have been held with most encouraging and practical results. They now intend to make the instruction more widespread.

Here are some views as expressed by different railroad surgeons in answer to a letter sent out by Dr. M. J. Kenefick, of Algona, Ia.:

Dr. Denney, of the Chicago, Burlington, and Quincy, replies: "We have first aid packages at certain points on our lines, but at many places where doctors can be had on short notice, we have not been paying much attention to this, excepting at some of our larger division points." Dr. Plummer, of the Rock Island, says: "There has never been any instruction in first aid to the injured given to the employees of our road. We had a limited number of the emergency boxes containing dressings suitable for first aid in our trains and in some of our stations, but the management of the road has seen fit during the last year to cut down our supply of them, so in the matter of first aid we are doing practically nothing." Dr. Bouffleur, of the Chicago, Milwaukee, and St. Paul, writes: "I am sorry to have to reply, No! Some of the earlier attempts on our roads were so unsatisfactory that some of our officials do not believe it practical. A scheme of limited first aid is being considered and will, I am sure, be of much service when fully inaugurated." Dr. Owens, of the Chicago and North Western, states: "There has been no systematic instruction in first aid." Dr. Sueve, of the Chicago Great Western, answers: "No, only to foremen at shops. Accidents usually take place where switching is done, and in Iowa, at least, there is usually a doctor at

that station or near it. First aid instruction is going on all the time through the public and medical presses, and through treatment by physicians; employees see what the doctor does and learn the principle of aseptic surgery."

One cannot study the statements continually made by railroad surgeons, without coming to the conclusion that it is of considerable importance to instruct men thoroughly in what *not* to do in case of accident. Dr. J. D. Williams, in a paper recently read before the railroad club of Pittsburgh, voices this sentiment when he says "that the prayer of the injured is not always 'Oh, Lord, save me from mine enemies;' but it is 'Oh, Lord, save me from my friends.'" He had in mind the treatment administered to wounds by ignorant but overzealous persons where it has been packed with tobacco "chews," covered with old germ bearing cobwebs, or soaked with black oil or kerosene. First aid instruction is not meant to turn men into amateur surgeons, but to prevent them from simply making bad worse, or from introducing needless complications which the railroad surgeon has to contend with or the railroad claim agent subsequently to settle for.

Two illustrations will be sufficient to demonstrate clearly the superior advantage of having men trained, not after any theoretical pattern, but according to some practical working scheme. The following instances may be found cited in the *Railway Surgeon*: "A fireman who had cut the artery in his wrist on a broken pane of glass in the round house one night in the mountains, was taken fifty miles on a light engine to the nearest doctor with a wound so badly bound up, that it bled constantly, and the injured man had been given several 'horns' of whiskey 'to keep up his strength,' with the result that the heart action had been stimulated and had so pumped out more blood. In this case the surgeon literally saved this man from his friends."

Dr. C. R. Dickson, of Toronto, is authority for this account of intelligent first aid service in mines: "An example is found at the Carbondale colliery at Jermy, Pa., and the attending surgeon at the emergency hospital is, as might be expected, a very enthusiastic believer in the practical value of first aid. Dr. M. J. Shields has practised during the whole of his professional career, about fifteen years, in the coal mining districts of Northeastern Pennsylvania, where a great many of the employees come from Great Britain, bringing with them their splendid training in first aid. Being a practical man, he appreciated the advantages of such training, and early in 1900 organized a first aid society of twenty-five men. The colliery employs four hundred men and has five

Railroad.	Question 1.	Question 2.	Question 3.	Question 4.	Question 5.	Question 6.	Question 7 and Remarks.
Boston & Maine.	Facts not obtainable.	No knowledge of any accident where waiting was for a length of time.	Not practicable.				
Bangor & Aroostook.	Facts not obtainable.	Facts not obtainable.	Perfectly feasible to equip passenger trains with a small emergency box.	We have nothing of the kind.	Yes	No	Not practical for so small a road.
Boston & Albany.	Facts not obtainable.	Facts not obtainable.	We provide each train with a small emergency box, but these are seldom used. As a matter of fact, we are frequently obliged to remove some of these cases because the material has deteriorated to such an extent as to become useless.			None and the very few accidents occurring would not justify the expense of maintaining a hospital car.	We have surgeons located at several places on the road, with a territory of twenty to thirty miles, and it is therefore possible to secure medical aid in case of accident.
New York, New Haven, & Hartford.	Facts not obtainable.	Facts not obtainable.	Yes				
Pennsylvania.	Facts not obtainable.	Facts not obtainable.	Equipping all baggage, mail, express, work and freight cars with terminals and offices and important stations with first aid boxes. Cars also provided with stretchers.	Yes	Employees to be so instructed by medical officers.	Company has plans for transportation of injured men in emergency by using a hospital car, but nothing as yet done toward building any of these cars.	
Lehigh Valley.	Facts not obtainable.	Facts not obtainable.	All our passenger trains are equipped with emergency cases, as well as freight stations along the line.	Yes	Yes	Yes	Yes.
Atlantic Coast Line.	Facts not obtainable.	The men who need hospital care after injury have had first aid quite well equipped, and were afterward sent to a hospital.	This is practicable, but it means a degree of care over supplies that is difficult to maintain. The provision of "first aid" material with the material men's service, but so far we have not reached a definite decision in the matter.	No	I doubt if the train men could be educated to render anything like efficient first aid. The application of the simple measures in a "first aid" package.	Yes, but it is used more for the transportation of sick men to the hospital than for injured men. The latter are sent in by express and easiest train.	This would be expensive beyond the value of the equipment. The infrequent use of the car would lead to neglect, and its condition would not always be adjusted to the best interests of the injured.

Railroad.	Question 1.	Question 2.	Question 3.	Question 4.	Question 5.	Question 6.	Question 7 and Remarks.
Casapeake & Ohio.	Surgeons are located in general terms along the line of the C. & O., every station having a first aid kit, and that prompt medical aid can be rendered in every emergency. We have never had any serious results from delay in obtaining medical aid.	only a short time.	The emergency boxes No. 1, except stretchers might be furnished each passenger car and first aid kit, but not think it necessary, because we are able to render such aid along the line of the road.	No, except stretchers.	No; for the first dress ing frequently done on the line of the U. S. army stretchers, which these are placed either in caboose or baggage car of each train, and general hospitals belonging to the railroad on the line.	Yes, for transportation of smallpox cases to detention hospital.	No; our stretchers are constructed on the lines of the U. S. army stretchers, which these are placed either in caboose or baggage car of each train, and general hospitals belonging to the railroad on the line. special arrangements with railroad companies and general points for the care of injured patients unable to be moved to the general hospital.
Grand Trunk.					Arrangements being made whereby our boxes of the Grand Trunk will be in strict accordance with the standard system of instruction in first aid, and the injured patients are instructed in the International Association of Railway Surgeons. The instruction are to be held at Port Huron and other points shortly.		Referred to Interstate Commerce Commission. Have medical and surgical departments, with physicians located at numerous points along the line. Their retainers are required to answer promptly calls for aid both for our passengers and employees injured on the line.
New York, Chicago, & St. Louis.	Facts not obtainable.	Facts not obtainable.	We consider it feasible to provide first aid boxes with a supply of medicine for each car, and to have first aid kits in each car, and to have first aid kits in each car, and to have first aid kits in each car.	Yes.	Consider it practical.	No.	Feasible, but it does not seem necessary.
Albany.	Facts not obtainable.	Facts not obtainable.	Possible to provide first aid boxes with a supply of medicine for each car, and to have first aid kits in each car, and to have first aid kits in each car.	No.	No.	No.	It would not be practicable. We have a hospital system.
Marquette.	Facts not obtainable.	Facts not obtainable.	Taking up the question of providing cars with small emergency boxes, and to have first aid kits in each car, and to have first aid kits in each car.	We have some supplies. Think it practical on our trains for emergency work.	No.	No.	Not feasible. The company appoints a good many local surgeons at different points along the line, and the injured are quickly provided with the care of a competent surgeon.

Railroad.	Question 1.	Question 2.	Question 3.	Question 4.	Question 5.	Question 6.	Question 7 and Remarks.
St. Louis & San Francisco, "First Aid System."	Facts not obtainable.	Facts not obtainable.	Considering the matter of first aid to injured, "first aid to injured."				
Chicago, Milwaukee, & St. Paul.	Facts not obtainable.	Facts not obtainable.	No answer.				
Colorado Midland.	Facts not obtainable.	At least immediate medical aid.	Yes, our company provides emergency boxes, provided by our medical department.	Medical boxes always on hand for emergency work.	Our trainmen are so instructed.	No	Not feasible or practicable for this company.
Rock Island System.	Facts not obtainable.	Facts not obtainable.	Consider it feasible to provide each passenger with a small emergency box for "first aid."	We have at present time supplies on some of our trains.	Considers it practical to have trainmen re-instructed a few such times.	No	Think it would be a good plan to have a hospital car, but the present mode for transporting injured passengers proved to be very satisfactory.
Chicago Great Western.	As far as known, only one.	One hour.	It is feasible, but in my opinion useless and unnecessary, because it runs through a populous country and doctors are always available. It would cost 100 times out of 100 at or near stations, and when they occur away from stations and the emergency boxes are not to be gotten at because of steam, smashing up, etc.	No. We have had, but have discarded them because we found it impracticable.	Not on our lines; but on lines running through a sparsely settled country, yes.	No	In our opinion unnecessary and impracticable, because they would only be of questionable use when accident occurred near their station.
Chicago, Burlington, & Quincy.							Reply to inquiries that we have not the information you ask for.
Union Pacific.							Referred to Interstate Commerce Commission Report.
Chicago & North-western.	Referred to Interstate Commerce Commission Report.		Our experience has not indicated the necessity thereof.	On work trains only.	Not practised to get any definite result.	In connection with work train.	Its use would be very limited except in a section of country not well settled. The above section and communication between towns and the appliances and help securable in ordinary towns does away with the necessity of such appliances.
Northern Pacific.	Facts not obtainable.						Have two large hospitals on this system where employees are cared for, and outside of hospital points we employ local surgeons, who, in case of accidents, employees receive immediate attention and aid.
Chicago & Alton.	None.	Immediate aid.	Provide each passenger car and caboose with a small emergency box.	Yes	Yes	No	Do not think it necessary with plan adopted.

Railroad.	Question 1.	Question 2.	Question 3.	Question 4.	Question 5.	Question 6.	Question 7 and Remarks.
Missouri, Kansas, & Texas.	Facts not obtainable.	Facts not obtainable.	Discontinued use of and adopted policy of employing local surgeons. Their location is such that a train is never further than 10 miles from a local surgeon.	All surgeons are provided with supplies, and in case of accident are immediately called upon and given. All trainmen carry a list of their names and addresses.	Impracticable, for the reason that experienced persons in many instances did more harm than good.	No.	Company maintains a large hospital at No. 10, has arrangements with hospitals at sundry other important points.
Seaboard Air Line.	Facts not obtainable.	Facts not obtainable.	Consider it feasible to provide every passenger car and caboose with emergency boxes for first aid to injured.		Employees should be properly and thoroughly instructed how to use appliances.		
Missouri Pacific.	Facts not obtainable.	Local surgeon hastened to injured immediately.	Do not consider it feasible to have such supplied. Have tried it and failed.	All private cars for passenger use are provided with both medical and surgical cases. All work and wrecking trains are provided with first aid boxes of both medicines and dressings.	You cannot make uneducated persons like surgeons. They can do little with surgical dressings.	No; think it would be superfluous in their system.	Have two large general hospitals and eleven emergency stations. We can pick up a man and send him on to the hospital almost as quick as your city ambulance could do the same work.

main gangways. He divided his men into squads of five, distributing one squad along each gangway. The chief of each squad was selected, after passing an examination on first aid to the injured, and in his care was placed a small box containing simple appliances. Each member of the squad carries a first aid packet with him, and there is a folding stretcher in each gangway. As is customary in first aid training the men are taught to forward a short description of the accident by the messenger who summons the doctor. An actual example of such a message follows:

FIRST AID ASSOCIATION,
JERMYN, PA., June 4, 1903—1 p. m.

Dr. SHIELDS:

Sir: Ed. Powers requires your attention at his home. Had his head squeezed between car and mule; right eye black and swollen; cut on eyebrow will require stitch; blood running from right ear, right side of face contused and swollen. Several minor bruises about face. No injuries about body.

Respectfully,
(Signed) DOWD.

What kind of instruction, and how much, should be given is the question that naturally comes to mind. One chief surgeon remarks that corporations, like railways, organized and conducted primarily for profit to stockholders, are not likely to take kindly to any suggestion for reform unless it can be shown that there is a business side to the proposition. There should be no difficulty, he thinks, in showing that there is a great loss annually of time and money to the roads by reason of improper aid to the injured, rendered at the hands of uninstructed employees. There are two or three elementary principles that should be understood by employees which can be taught them in five minutes. Such instruction has been well outlined by Dr. Brockman as follows: "This instruction should be brief, to the point, and cover the following topics: *a*, how to stop hæmorrhage; *b*, the importance of keeping the patient warm and removing him to some house or car; *c*, how to handle a victim of a fracture with the least pain and injury; *d*, how to protect open wounds; *e*, how to treat burns.

"*a*. Every workman should know in a general way the location and course of the large vessels in the extremities and where pressure can be best made over them to control dangerous hæmorrhage. He should be taught that slow bleeding from a lacerated or crushed extremity will probably stop if the limb is elevated for a short time, but if the flow is profuse, i. e., from an artery, it will be necessary to apply constriction above the knee or elbow. He can in a few minutes be taught to apply the Spanish windlass until the flow stops,

that he must then take off every half hour to see if the wound will bleed again. By this intermittent pressure there will be but little danger of gangrene.

"b. Every workman should be taught the importance of getting the injured man to some warm place as soon as possible, for cold has much to do with causing shock and death in the seriously injured.

"c. He can be taught readily how to bandage the legs together or to a board or long stick so as to hold the broken bone as still as possible, or how to make a temporary splint out of a blanket, that will hold the limb in position until it can be attended to by the surgeon.

"d. Most important of all is how to treat open wounds, for these constitute the great majority of the serious accidents and here is where he should be instructed to do the least that will meet the indications. These are to stop serious hæmorrhage, and by the use of some sterile material to protect the wound from further infection.

"e. He should be taught how to protect the burned surface with a suitable dressing."

Dr. A. O. Williams suggests that as every railroad man carries a time card and all their work is governed by that card, it should be utilized for this purpose also. Incorporated into these cards and made a part of their study, should be some of these first principles instilling cleanliness, the adding of heat, when necessary, and the means of controlling hæmorrhage.

Over the Pennsylvania system the employees to be instructed will include all passenger and freight trainmen, including engine men and firemen, and other employees at terminals, yards, shops, etc. Instruction will be given by the medical members of the relief department at convenient points. It is to consist of instruction how to place the injured on stretchers, how to transport the injured, simple directions for taking primary care of wounds, fractures, burns, shock, etc., without the use of drugs; also instruction regarding emergency treatment of pain, unconsciousness, convulsions, and heat prostrations.

As a criticism upon this teaching of laymen, one doctor expresses the novel opinion that where surgeons are many and good, such instruction would seem to be *really trespassing, infringing, on the rights of physicians and surgeons*, and doing the injured person an injustice. In his opinion, it is fundamentally impossible to teach train men a few lessons on how to render proper first aid, and thinks the best that can be done is to teach them what not to do. As far as hæmorrhage is concerned, nearly all the injuries resulting from rail-

road accidents are of a crushing nature, so that the application of a tourniquet is not needed. His experience in the question of straightening legs in case of fracture by these men has been that the condition has been made worse, and, in one instance, a simple fracture was converted into a compound. "About all the benefit to the medical profession," he writes, "is that it affords some of our new railroad surgeons a chance to give instructions to men in shops and employees along the line, which will help to advertise them."

TABLE IV

Shall Railroad Employees be Instructed in First Aid?

Yes.

Northern Pacific.

THE HOSPITAL CAR.

Upon the subject of hospital cars, there seems to be more definite opinion, the majority being against their introduction as unnecessary in railroads running through well populated districts. Running through sparsely settled country can hardly be charged to such railroads as the Pennsylvania, the Lehigh Valley, and the Erie, all three of which either have them by this time or are having such cars built. An illustration of the cars to be placed in the service of the Erie Railroad was published in the *Medical Record* for May 7, 1904. The article is a sample of the difference of opinion held upon this topic by men apparently equally competent to judge. Dr. Sanford writes: "It may be safely said that there is not a physician or surgeon present, who does not believe that the need of establishing such a system of hos-

pital cars upon our railroads is imperative, and it would seem to be the duty of railroad corporations to make such provision for the prompt relief of injured passengers. As we recall the memory of the distressing railroad accidents of past years, the more impressed we must be by the horrors of these recent recurrences in the West and South. It is a sad thought to picture the mangled and dying on beds of snow, or often in the dingy room of some wayside cabin, or even as was recently the case, in a barn, being cared for by a chance physician who perhaps himself only escaped total disability, assisted by the willing laity in his feeble efforts to alleviate the sufferings of the many injured, while miles away, after much delay, a relief train is being prepared as quickly as possible, but slowly and inadequately supplied with a few surgeons, and possibly a nurse, to be sent to the scene, hampered in their work by lack of facilities. Allow the comparison with the immediate departure of a hospital car with its staff of a goodly number of surgeons and nurses, prepared for all emergencies." It was with the intention of securing, if possible, data that would corroborate such delays in the care of the injured, that the first two questions were asked. The negative answer in all letters, except one, where one hour was stated as the time, would lead one to think that such occurrences were very rare, or that they were forgotten as soon as possible. One thing is true, that serious accidents are more numerous in the vicinity of switches, and therefore not far from town, so that the baggage cars, etc., can quickly be appropriated for use in transporting the injured to hospital. Another reason for its failure to meet with approval is the necessary cost of building such cars, as proposed by Dr. Sanford, and maintaining them. Each of these cars will be 50 feet long, and heavily constructed, and everything will be painted white, as in a hospital ward, the floor being covered with white rubber in block form. Each hospital car will be divided into two compartments, one 36, the other 14 feet long, separated by heavy sliding glass doors of frosted plate, wide enough for a stretcher to pass through. The larger compartment, corresponding to a hospital ward, will contain eight white enamelled iron bedsteads. There will likewise be two swinging beds, suspended from the roof, to do away with all jarring motions. Each bed will have a frame for enclosing the bed with white curtains.

Dr. D. S. Fairchild has described a car which has been constructed on the Chicago and North Western road, and has been attached to the wrecking train at Clinton, Ia. This car was

overhauled and reconstructed by the men themselves, outside of regular working hours, and the only expense attached to it was the material used, as the men gave their services free of charge. The actual cost to the railroad was not more than \$100. An old coach was secured and the inside torn out and refitted. In one end, five sections were made, each having an upper and lower berth, accommodating ten persons in all. Adjoining these sections on one side, are three closets, one the water closet, one a clothes closet, and the third, the surgeon's supply press; in this last closet are shelves of various sizes, in which supplies are kept, in a compact and accessible form. The central part of the car has two tables at one side, arranged like those in a dining car; on the opposite side, is a writing desk and a seat, running parallel to the side of the car. This portion is well supplied with windows. At the other end, is a cupboard and ice box, and opposite to this a cooking range. In the top is placed a stretcher, also an operating table. Whenever the car is called, this table is taken down and firmly placed, one end resting on the side table, the other end, being supplied with folding legs, rests on the floor.

Answers to the letters sent out show that the following four railroads have hospital cars of some kind, usually attached to a work train: The Atlantic Coast Line, the Lehigh Valley, the Chesapeake and Ohio, and the Chicago and North Western. The Pennsylvania road has plans for a car suitable for the transportation of invalids, which may in emergency be used as a hospital car, but nothing as yet has been done toward building any of these cars.

CONCLUSIONS.

As a result of the study of the present status of railroad emergency work, the following conclusions seem justifiable:

Questions 1 and 2.—Data are difficult to obtain, but the answers would indicate that a delay, of considerable period and involving avoidable loss of life, was rare.

Question 3.—The balance of proof is in favor of the supply of trains with some form of emergency package such as could be of service in the hands of laymen, preferably such packages as devised by Dr. Crutcher, of the Chicago and Alton, or by Dr. Brockman, of Ottumwa, Ia. In addition to this, the surgical chest for use of the doctor in the baggage car, simple yet efficient. The objection that it is usually destroyed in the smash up is true only in head-on collisions.

Question 4.—A considerable number of railroads are adopting such a plan. A few have tried

and found it wanting, and have discarded the package.

Question 5.—With the adoption of the emergency package, all are agreed as to the advisability of some simple plan of instruction to railroad employees. Its practical working is doubted by some, but others are equally positive of its beneficial result.

Question 6.—The hospital car, while a distinct advantage at the time of an accident, is still problematical as to its value, on account of its infrequent use, and consequent neglect; also on account of its cost of introduction and maintenance. One car would not be sufficient, but a system of hospital cars would have to be instituted.

MERALGIA PARÆSTHETICA, FOLLOWING TYPHOID FEVER.

By L. L. VON WEDEKIND, M. D.,

U. S. S. *Cincinnati*,

SURGEON, UNITED STATES NAVY.

The patient, an officer, aged 30 years, was, in November, 1903, admitted to the United States Naval Hospital, Cavite, P. I., as with febris enterica. The admission diagnosis was confirmed in a few days. A typical, but very severe type presented, and in January, the patient had a relapse, extending the time of treatment in hospital to over ten weeks, and the convalescence at the end of this time was slow. To obtain the benefit of a different climate he was sent north, to the United States Naval Hospital at Yokohama, Japan, arriving there in March, 1904, where he remained for a period of ten weeks, returning in May, 1904, to duty, when he was assigned to this ship. From the date of his illness to the time of his return to duty, some six months elapsed.

Upon reporting for duty I noted that he showed the evidences of a recent illness, and though both willing and anxious to do duty, it became evident that his willingness was away ahead of his ability, and he was consequently relieved and sent home to recuperate.

Immediately upon reporting for duty in May, the patient became an officer of the watch and I noticed his somewhat peculiar gait, but for a time made no mention of or comment upon it, supposing it to be a personal peculiarity. He would rest against anything while on duty which might be convenient, and after a tour complained of being tired and of pain in his legs. He never expressed a desire to exercise ashore. Knowing of his previous illness and that he had been in hospital, I inferred that the weakness and pain in his legs was natural to a condition of completed convalescence after a six months' rest, also that with exercise on deck, he would, in the

course of a short time, gain not only increasing strength and vigor, but that the regular exercise and out door life were the best possible means to perfect recovery. After the lapse of about a month, noting no improvement, I inquired as to the cause of his peculiar walk and received the following history:

While under treatment in Yokohama, and for no apparent reason he can assign, he was suddenly attacked with left facial paralysis, this condition remaining for twenty-one days. During his illness, while in the Philippines, he noticed that his thighs had to a greater or less degree lost sensation; that, while in bed, his hands touching the thighs, the sensation was in places, different, and that occasionally he had a very peculiar tingling sensation in the areas of anæsthesia. Owing to his illness, this condition seems not to have impressed him as being peculiar, for he referred it to his general illness, and therefore made no mention of it as it was in no way disagreeable, being called to his attention only when his hands happened to touch the anæsthetic spots. While completing his convalescence in Yokohama, leading a pleasant out door existence in very pleasant surroundings, exercising purely for pleasure and not overdoing the exercise at any time, he noted no ill effect, but found, on the contrary, a diminution of the tingling and a decided diminution of the anæsthesia; though the borders of the anæsthetic zone remained fixed, the sensation to touch was gradually returning.

During his first tour of duty after joining this ship he was very tired and found that in addition to the anæsthesia and tingling, each of which returned during the first watch, he also suffered from myalgia in the thighs and legs, and found his feet swollen and tender. On account of an almost complete rest of a few days between tours and to the subsidence of all symptoms which had occasioned discomfort, he made no mention of his condition, and found upon the completion of the second tour a similar state of affairs, with cessation after a complete rest. His appetite being excellent at the time and his digestion perfect, he very naturally concluded that his strength had not fully returned, but would in due course, and so, until I questioned him, he made no complaint, other than of extreme weariness, and he used to mention in mess that his legs pained him.

An examination shows almost complete anæsthesia of the external and anterior aspects of each thigh, the outline on each being identical, one spot about the size of a silver dollar, of exquisite hyperæsthesia along the inferior line of demarcation on the right thigh only. Digital pressure in this spot discovers pain deep seated, such as would be noted in a subperiosteal abscess, but under the hyperæsthetic spot only, and under pressure only. The zone of anæsthesia is like "inlaid boards," the tingling similar to "the after effect of striking the funny bone." Myalgia is general in both thighs and legs after continued exercise, disappearing completely after a long rest. A spot on the right side of the chest three inches below and to the right of the nipple, which he terms "a heat spot," will suddenly flare up and burn for a moment and as suddenly cease.

I have questioned very closely as to the normal sensation in the soles of the feet, but he denies any loss in this region, still the manner of and the awkwardness and uncertainty noted in his gait, both upon reporting and since, suggests a difference there, as well as a loss of complete control of coordination.

The general nervous system is badly shattered, as he has little if any control, and irritability, very foreign to him, is constant. What is usually termed lumbago is present now and again. The right foot, I have occasionally seen, both in walking and sitting with the right leg crossed, to drop, exactly as in wrist drop, but this is not constant and the patient has control. Still it is present at times, and that it is not an attitude, its presence in walking demonstrates.

The treatment has been rest, strychnine, and massage; the results, not great. Judging, however, from his condition when he reported for duty and his statement regarding the return of sensation during convalescence from typhoid, the ultimate outcome should be good.

The exact area, conditions, and symptoms in each thigh, with the exceptions noted above, indicate the involvement of the same nerve on each side, and at its origin and in addition to the external cutaneous, especially on the right side (the pressure?), may include the strands of some others.

The patient's discovery of the anæsthetic spots, during his attack of typhoid, fixes the origin of the present trouble, and doubtless also that of the facial paralysis. The personal history is absolutely negative.

Actual Indications for Vaginal Hysterectomy.

—Richelot, in the *Revue de chirurgie*, for November 10, 1904, establishes a parallel between abdominal and vaginal hysterectomy. He discusses these two methods in connection with uterine fibromata, cancer, and pelvic suppuration. He favors abdominal section for fibromas of moderate size as well as for those which are very large. If, however, the fibromatous uterus is small, movable, hard, painful, and disposed to bleed, and if the abdominal wall is thick, he advises vaginal hysterectomy. With regard to cancer there have been many illusions as to the abdominal method. Statistics show unequivocally that even if the connective tissue and the glands are removed, recurrence will follow as quickly after the abdominal as after the vaginal method.

The author believes that he has rendered good service to at least 18 or 20 per cent. of the cases in which he has performed vaginal hysterectomy for cancer, survival in these cases continuing from three to twelve years. He believes it will be unreasonable to look for results which will be much better than these, and he therefore states that he shall continue to operate for cancer by the vaginal method. With reference to pelvic suppuration the abdominal method enables one to see the field to better advantage and remove only that which is strictly necessary. If, however, the tubal collections of pus are very septic, it is better to remove them by the vagina and perform vaginal hysterectomy.

THE VASODILATORS AND CONTRACTORS.

By GEORGE W. GREENE, M. D.,

AUBURN, N. Y.

We are taught in works on therapeutics that alcohol dilates the arterioles and at the same time causes increased vigor of the systole. So much is the systole increased that, notwithstanding the dilated arterioles, the blood pressure is materially raised. It is, therefore, theoretically as well as clinically the ideal heart stimulant. There are very few physicians who would not give alcohol in sudden heart failure, as, for example, in syncope or heart failure in pneumonia.

It would seem, looking at it from a theoretical standpoint, that it would be the ideal treatment in hypertrophic dilatation with degeneration. But here sadly enough theory and practical experience are seriously at fault. I have repeatedly seen serious cardiac insufficiency occur in people who were habitual indulgers in alcohol. More than that, I think that the use of alcohol renders the prognosis unfavorable. But here digitalis, a drug which contracts the arterioles as well as the heart, and causes prolonged systole and very materially raises the heart pressure, is the drug of all others. I seriously doubt if there will ever be found a substitute for digitalis. Dr. Oliver Wendell Holmes calls it the opium of the heart.

There is another drug, however, with almost identically the same physiological effects. I refer to ergot. But who ever heard of giving ergot in heart trouble? It is alleged that the indication for digitalis is low arterial pressure, but to show that this is not true I will simply point to chronic myocarditis; those cases where there is evident cardiac insufficiency with dispnœa, and dropsy of the feet, cases without valvular trouble where the heart goes tip tap, tip tap. These cases have marked low arterial pressure, yet in them in my hands digitalis is worse than useless, positively injurious. In these cases the nitrites, of which nitrite of sodium is the type, occasionally accomplish wonders, and yet the nitrites lower blood pressure by dilating the arterioles. They relieve the heart by taking the load off, and rest the heart by giving it less to do. To illustrate:

About a year ago I had an old man who without valvular trouble was water logged, with very evident pulmonary œdema. He was unable to lie down, his heart sounds, though clear, were short and sounded like the ticking of a watch, yet this hopeless man under two grains of nitrite of sodium every three hours so far recovered that he resumed his work of a gardener.

Another use of the vasomotor contractors and dilators, of which medical literature says very lit-

tle, is their use in headache. When the patient looks like a corpse, he is almost always relieved by a full dose of nitrite of sodium or nitroglycerin, while in the congestive variety, where the face is red, the eyes are suffused, and the carotids throbbing, a full dose of fluid extract of ergot will work wonders. Ergot and nitrite of sodium are physiological antidotes; so also are digitalis and nitroglycerin, and yet no less an authority than Da Costa combines them. The only reason that they are not both inert is that the nitroglycerin evaporates and leaves the digitalis.

Another use of the vasodilators which is highly extolled is in the treatment of arteriosclerosis or cirrhotic kidney. They dilate the arterioles and lessen the danger of apoplexy. If two grains of nitrite of sodium are combined with one hundredth of a grain of bichloride of mercury, they will, at least theoretically, absorb the new connective tissue. I think this fact has been proved clinically. I believe after repeated trials that the nitrite of sodium is of great value in the treatment of anemia. It dilates the arterioles and hastens the elimination of the waste material. This waste material contracts the arterioles, which hinder the elimination and thus keep up a vicious circle, which can be completely counteracted by vasodilators, of which I think nitrite of sodium is the type.

I approach the subject of the treatment of pneumonia with misgivings, for almost every physician has his own idea of the treatment. On only two drugs is there unanimity of opinion, alcohol and strychnine. There are very few physicians who do not give them at some time during the disease. I myself give alcohol only when it is indicated by heart failure.

Digitalis is highly recommended, because it raises blood pressure, but I never heard of its companion drug ergot being used. Many very competent observers condemn it. No less an authority than the late Dr. Loomis was one of these. Dr. Elsner has lately recommended adrenalin chloride. A man with pneumonia is like a man running up hill. His heart is beating at twice its normal rapidity, and he is using up strength which will be needed before he has passed the crisis. I believe in veratrum viride in this condition, and I give it for two or three days in sufficient doses to soften the pulse. When the heart begins to fail I give strychnine and alcohol. Pneumonia is a self limited disease, and is probably the least affected by treatment of any disease. In the Massachusetts General Hospital they have kept an accurate record of the pneumonia cases and the treatment for a hundred

years. Dr. Loomis, when studying these records, drew a line showing the death rate; the higher the death rate, the higher the line. During this time every kind of treatment was in turn in vogue, yet strangely enough the line was practically straight. Dr. Loomis used to classify pneumonia as follows: Cases which you could not kill, cases that cannot be saved, and cases in which judicious treatment will turn the scale favorably.

There is one other class of cases where vasodilators are of great value. I refer to eclampsia. During an attack of eclampsia and immediately preceding it, there is an enormous rise of arterial pressure. It has become a recognized plan of treatment in epilepsy to advise the patient to carry pearls of nitrite of amyl, and when an attack is impending to crush one on a pocket handkerchief and inhale. During puerperal convulsions, Playfair recommended veratrum viride in large doses, and Edmunds advises it without regard to dose. I believe its action is due to the dilatation of the arteries of the brain. If I am ever so unfortunate as to have a case of puerperal eclampsia I shall inject 10 minims of solution of nitroglycerin.

Death from chloroform is caused by extreme vascular dilatation, the victim, in fact, bleeding to death into his own veins. Judging from the therapeutics of adrenalin chloride, the idea struck me that perhaps it would be a suitable prophylactic to inject 10 minims of adrenalin into a vein before administering chloroform. I wrote to Professor Hare, stated the facts, and asked his opinion. He answered that the best surgeons now used it for that purpose. In the last edition of his book I see he now recommends it.

To conclude, the vasomotor dilators and contractors are among the most important therapeutic agents we have at our disposal.

The Bradford Street Hospital, Brooklyn.—Charities Commissioner Tully is planning to make the Bradford Street Hospital, in East New York, one of the largest and most modern institutions of its kind in this borough. The commissioner made formal application to the Board of Estimate on January 13th, requesting it to authorize the purchase of 100 additional feet of land north of the present hospital building. The question of enlarging the present hospital has been agitated for a long time by the citizens and civic organizations in East New York. The building was formerly used as a station house in the old town of New Lots, and is in a deplorable condition. It is not fireproof, and there are no fire escapes from the upper floor.

DELAYED RESULTS OF A WOUND OF
THE BRAIN.

By PHILIP F. O'HANLON,

NEW YORK,

CORONER'S PHYSICIAN.

It has been said at various times by observing members of our profession that the coroner's office does not often furnish much to the literature of medicine. Be this as it may, there is good reason for this dearth of information from the channel in the fact that the life of a coroner's physician is pretty well taken up with attention to his duties. In the borough of Manhattan alone some six thousand cases a year are despatched by those employed to do the work. Out of this number of cases between 1,500 and 2,000 autopsies are made. To any one familiar with the distances between cases it would be an easy matter to compute the time taken up in travel alone. Travel entails fatigue and the latter is not conducive to pen pushing of facts after all are through for the day. I will be glad to break the ice in this matter, if it meet with any benefit to my brothers and relate facts as they come along, facts, mind you, not opinions. This being so, I will of course be excused from having to elaborate or argue on the subject. It is a fact that a number of persons die, and the deaths reported to this office upon being investigated post mortem do not explain any cause, even after chemical and microscopical efforts have been made; and these examinations are made in the laboratories of our medical colleges by most competent and hard working investigators.

Imperfect clinical histories is one of the most irritating conditions presented in many of the hospital coroner's cases. Effort properly directed by the industrious internes would, if persisted in with proper spirit, largely tend to eliminate this unhappy fact; the gentlemen devoting their time and the best days of their career would be gainers to as large an extent as the coroner's physicians, and the medical world and the public in general would reap an advantage far beyond the most lurid dreams of the imagination.

No fiction penned can picture stranger truths than those seen by us. Books do not begin to tell such facts, that seem to be almost beyond belief, and, when related, do not awaken responsive credit. To relate a case in point:

During the excavation for the foundations of a large department store here some years ago a man by name McD. had an altercation with the night watchman, in which he made an effort to hit the latter with an iron crowbar. The watchman pulled out a pistol and at close range fired

and the disturber fell to the ground. Upon examining him it was found he had a wound of the temporal bone. He was taken to a large hospital where the "scalp" wound was dressed. The next morning, the man walked into Jefferson Market Police Court and there made a complaint against the watchman. Time passed, two months elapsed, McD. working all this time. A little later he was taken with fits in the street, brought to a hospital, and a diagnosis was made of epilepsy. He was allowed to go out again, and, to make a long story short, McD. used to "throw a fit" quite often and quite as often the old diagnosis, epilepsy, followed as a matter of course. One day he was taken to a large down town reception hospital, and it so happened that an x ray of his head was made and McD. went again upon his merry way. Time passed on and anon McD. wound up in Bellevue because of the usual epileptic attack on the street. He remained at this hospital, where a diagnosis of brain abscess was made, and in due time McD. reached the coroner's room at the morgue.

An autopsy made revealed a bullet resting beneath the anterior lobe of the right hemisphere at the base, to all purposes a harmless foreign body so far as the lead itself was concerned. The track of this bullet was plainly visible through the brain tissue, beginning at the left temporal lobe and passing across to where it was found. An examination of that part of the brain broken down into an abscess showed a small piece of lead, to which adhered a sharp piece of bone, which had set up the irritation which resulted in the formation of the abscess. Investigation showed that McD. had been shot 18 months before, at the time and place stated in the foregoing narrative, and no one was found who suspected the true cause of the trouble, except the x ray enthusiast who had a skiagraph, and to whom I went, relating the case, and this skiagraph showed the bullet to be in the place where I found it at the autopsy.

Rather interesting, is it not? Some day when I again have a few moments I will continue to relate what may be of interest, even though it staggers belief. I think this case "puts it up" to the gentleman of crowbar fame of whom the books speak to the astonishment of the medical student reader. Organs particularly capable of giving symptoms during life with no corresponding post mortem lesions are the heart and the brain, and many a good premium life insurance companies have lost by too great importance being attached to symptoms that afterwards clear up and are not due to disease of these organs.

121 WEST NINETY-FIFTH STREET.

NEW YORK MEDICAL JOURNAL

AND

PHILADELPHIA MEDICAL JOURNAL.

A Weekly Review of Medicine.

ESTABLISHED IN 1864.

Edited by

FRANK P. FOSTER, M. D.

Published by the

A. R. ELLIOTT PUBLISHING COMPANY.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, JANUARY 21, 1905.

A WORD ABOUT IMPROVEMENT.

To Our Readers:

We respectfully call your attention to the *New York Medical Journal and Philadelphia Medical Journal* for the first issue of the new year.

The *Journal* will be vastly improved for 1905 over any previous year in its history.

For instance, the first issue of the new year was made up of 52 pages, or 104 columns of text matter, which makes it the largest weekly medical journal on the Atlantic seaboard.

Its contents were as follows:

Lectures, one.....	4 pages,	8 columns
Original articles, six, by eight authors.....	21 "	42 "
Subscribers' discussions, three authors.....	3 "	6 "
Therapeutical notes.....	1 "	2 "
Editorials, ten, one signed.....	4 "	8 "
News items.....	5 "	10 "
Pith of current medical literature.....	8 "	16 "
Proceedings of societies.....	1½ "	3 "
Book notices.....	1½ "	3 "
Miscellany.....	1½ "	3 "
Official news.....	1 "	2 "
Births, marriages, and deaths.....	½ "	1 "

Total, 52 pages, 104 columns

There were also forty pages of clean, ethical advertisements from houses whose commercial standing and products are beyond reproach.

For typographical effect, quality of paper used, and for press work, the *Journal* stands to-day unequalled by any weekly medical journal in the world.

We ask your careful scrutiny of the first issue for 1905, which was but the forerunner and criterion of the numbers which are to follow.

A. R. ELLIOTT PUBLISHING COMPANY.

THE BUFFALO CAMPAIGN AGAINST CANCER.

Since our last issue went to press the newspapers have contained accounts of an alleged 'successful serum treatment of cancer discovered in the Gratzkoff Laboratory of the University of Buffalo—at least of its measurably successful employment on mice inoculated with a disease resembling cancer in its gross features. Our readers will recall the fact that a number of months ago the newspapers proclaimed the discovery in the same laboratory of the germ of cancer. That announcement proved to be fallacious—premature, as the newspapers now put it—and a realization of its fallacy is said to have led the medical officers of the laboratory to resolve not to give out anything more for publication without the most complete evidence of its truth. This resolution became known to members of the profession in Buffalo, and they consequently entertain a general belief, as we have taken pains to ascertain, that the present announcement is not "premature."

The story is that a mouse affected with cancer was received at the laboratory some time ago from Copenhagen; that from that mouse there were inoculated from 150 to 200 other mice, "all of which now have cancer;" and that treatment of these inoculated mice with a serum prepared in the laboratory has produced the disappearance of small tumors and arrest of the growth of larger ones. It purports to have been given out from the laboratory that the experiments thus far made justify the application of the treatment to human beings, though it is admitted that the disease in the mice must yet be studied for a much longer time before it can be said that the investigation has been followed to its legitimate conclusion. Thus far, it appears to be sarcoma rather than carcinoma. As to the final result, the profession can only hold its judgment in suspense, but we certainly hope that the Buffalo laboratory will be found to have added materially to our knowledge of cancer.

THE ACCURACY OF CLINICAL THERMOMETERS.

Two important factors have contributed much to bring about the present unsatisfactory conditions in the clinical thermometer industry, unsatisfactory alike to the manufacturer, the dealer, and the user. One of these factors has arisen

from the somewhat unreasonable demands of those who use these thermometers, and is due to want of information as to the degree of accuracy essential in the use of a clinical thermometer. The dealer, as a result, finds it difficult to dispose of a thermometer that has so small a correction as 0.1° F., the demand being for thermometers that need absolutely no corrections, and these conditions would hold even if the certificate showed an error of only 0.01° . The mere fact that any correction is required, although entirely negligible, seems to mean to the uninformed user, and indeed even to the well informed, that the thermometer is not a good one. These conditions have led the dealer to demand of the manufacturer thermometers with accompanying certificates that have zero corrections at all points of the scale for every thermometer, and here the second factor is introduced that has played so harmful an influence. It is almost impossible for the manufacturer to meet this demand honestly. It would mean the rejection of a very large percentage of even his most carefully made goods, and it could therefore be done only at a very marked increase in cost over the prevailing rates, and all this without any real advantage to the user.

Unfortunately, some manufacturers have yielded to the pressure of competition and have furnished certificates with their thermometers showing zero corrections at all points of the scale, regardless of the real amount of correction required. It is no uncommon experience with the salesman to find a dealer who cares little whether the thermometers are in error by 0.1° or even 1° so long as the salesman will furnish him with certificates showing a zero correction at every point of the scale. The demoralization in the industry to which this has led can hardly be overestimated. It has resulted in filling the market with thermometers which are in many instances entirely untrustworthy, that have never been tested, but which are nevertheless sold with certificates showing all zero corrections. To their credit be it said, a number of manufacturers have made a determined stand against these conditions.

At the suggestion of all the interested parties,

the United States Bureau of Standards some time ago began the certification of clinical thermometers on a limited scale, and has now tested over ten thousand thermometers. With a view to increasing the general reliability of the product by removing as far as possible the factors previously discussed, and at the same time safeguarding the interests of those who use clinical thermometers, the Bureau of Standards is now considering the question of issuing a certificate under the following conditions: When a thermometer shows at the so called normal point (98.6°) an error not exceeding 0.1° and at other test points an error not exceeding 0.2° , the bureau proposes to issue a certificate containing the statement that it "has negligible errors." These errors are, in the opinion of the experts of the bureau, negligible for the order of accuracy that is essential in clinical thermometry. Thermometers having errors greater than this would then receive the usual form of certificate stating the magnitude of the corrections at the several test points. The proposed new form of certificate of the Bureau of Standards will not state the amount of the corrections, inasmuch as they are considered entirely negligible.

The proposed "blanket" certificate is intended to relieve the manufacturer and the dealer of the unreasonable objection made by the user to a thermometer having these small errors, and at the same time to guarantee to the user a degree of accuracy sufficient for every purpose. The Bureau of Standards directs attention to the fact that this proposed step is along the lines followed by the great German testing bureau, the Physikalisch-technische Reichsanstalt, which engraves on the thermometer the word "fehlerfrei" (meaning free from error) if the corrections at the three test points do not exceed 0.05° C. (about 0.1° F.). The proposed certificate of the Bureau of Standards would insure the same degree of accuracy at the "normal point," and is a little more liberal at the other points, where the demand for accuracy is admittedly less.

It is only fair to point out that in the proposed certificate of the Bureau of Standards the thermometer receiving it would read within about 0.1° of correct temperature near normal and with-

in 0.2° at other points. If a thermometer was broken or another substituted this would of course introduce the remote possibility of an apparent change of 0.4° in a patient's temperature, should it so happen that the first thermometer had read 0.2° high and the second thermometer 0.2° low, for example. At the present time the Bureau of Standards issues a certificate giving the magnitude of the corrections required at four test points, and certification is refused if the correction exceeds 0.3° F. The Imperial German Bureau has established a maximum limit of 0.1° C. (0.2° F.), while the maximum variation allowed by Kew Observatory (England) is 0.4° F.

These questions have been raised in the *Journal* with a view to getting further information as to what may be considered a "negligible error" in clinical thermometry, and with this end in view the editor invites a discussion of the subject by those who are interested and have given the subject some thought. It is of interest to note in this connection that the German Imperial Testing Bureau, as stated above, regards a correction of 0.05° C. (0.1° F.) as entirely negligible. The proposed certificate of the Bureau of Standards shows that it, too, is of the same opinion, going somewhat further (0.2°) at points other than the normal point. The important question is, Does the physician draw any conclusions as to the condition of his patient from an observed variation of 0.2° , 0.3° , or 0.4° F.? We should like to hear from our readers on this subject, as the Bureau of Standards would no doubt be largely guided by a consensus of expert opinion in the matter.

THE PHYSICIAN AS AN INVESTOR.

I.

From the amount of literature advertising "fake" schemes for investment with which the desk of the physician is flooded, it is evident that the wily fakir puts a very low estimate upon the intelligence of the profession. That this estimate is deserved, most of us who are in a position to know would scarcely deny. The fakir starts after the young physician as soon as his sign is swung to the breeze, and pursues him throughout his after-life with enthusiasm proportionate to the doctor's real or supposed financial success. It would seem

that the wily schemer holds the view that the readiness with which the physician can be induced to part with his hard-earned dollars is inverse to the difficulty with which he acquired them. The attitude of the physician regarding such little moneys as he may accumulate reminds me of the story of the Irishman who, by dint of seventeen years' hard work in carrying the hod, had accumulated something like \$400. He was induced to go to the races one day, and very promptly lost every dollar he had. One of his compatriots was condoling with him upon his loss, whereupon he retorted: "It's all right, Moike; come aisy, aisy goes."

About the first proposition that is submitted to the young doctor is a life insurance scheme. He is induced to buy life insurance upon the specious plea that he can pay at least a part of it, if not all, in life insurance examinations. This, he is informed, will give him a large acquaintance and a permanent position with the company. I do not know what the custom of the larger companies is at the present time, but in times past some of the most substantial life insurance organizations have been parties to schemes of this kind. Having secured the doctor's money, or, in the event of the *quid pro quo* being altogether life insurance examinations, the doctor's time and skill, he is promptly dropped by the agent, who then seeks new fields to conquer in the shape of other aspiring and struggling young practitioners.

Once the young physician has begun to progress, actually or presumably, as the case may be, he begins to be besieged by men who have easy money schemes. These schemes involve simply the backing of the promoters' ideas with the victim's money. It is strange that the doctor cannot comprehend the situation, yet he rarely does. The doctor is not victimized quite so easily as he once was, for if there has been any change at all, it must be in the direction of improvement—there was no room for retrogression. It is necessary to make the bait a little more glittering than before. The wily one approaches us now with a scheme for planting coffee beans on the top of Popocatepetl, and reaping gold dollars at the rate of a hundred a bean. We might be a little suspicious of this, but we find upon the list of directors—perhaps occupying high offices on the company's tempting paper—one or more

physicians of high standing. At the head of the subscription list appears the name of Professor So-and-so, a distinguished physician or surgeon, who has just subscribed (?) to five or ten thousand dollars or more of the company's stock. We are instructed to call the professor up by telephone and receive full particulars. We do so, and are assured by him that "it is really a shame to sell any of that stock, as the insiders want it all, but just to oblige Dr. Easy Mark and a few others of the professor's friends the company has consented, after considerable pressure, to sacrifice a small amount." Of course, the distinguished professor confirms the report that he has some stock in the company. He does not state, however, that he was one of the original promoters, nor that the amount of outlay which he has made in the purchase of his stock might be inserted in a mosquito's eye and kept therein for an unlimited time without reddening the conjunctiva of that diminutive insect.

It is high time that the physician awoke to a realization of certain fundamental facts of finance. I will briefly present several of the most important of them.

1. The man who has a profitable mining, land, or agricultural scheme to finance is not compelled to go into the office buildings of our cities or to the modest dwellings of our country practitioners and look up doctors for the purpose of inducing them to invest their hard-earned dollars. Had I a really excellent mining or other scheme to promote, I think I could spend my time much more profitably among capitalists than among doctors or other professional men. The amount of unused capital in America that is lying in wait for judicious and profitable investment is so great that even the fools should be able to understand the situation.

2. The legal rate of interest is established by our general financial and commercial conditions. This legal rate is supposed to be a safe rate, yet our men of great wealth, when they desire to make investments, buy government bonds, the interest upon which is about half the usual legal rate of interest. They do this because they consider the bonds the only investment which is absolutely safe. This is a hint that the physician who has a few hard-earned dollars which he is tempted to invest in wild cat schemes would do well to remember.

3. The most important point is this: With every

one per cent. of interest promised above the legal rate, the danger compounds. The difference in safety between an investment which promises five or six per cent. and one which, it is alleged, promises ten per cent. is something staggering.

4. It is well to remember that most of the men who have lost money in speculation have done it while "backing another man's game." The professional gambler considers this a very dangerous practice. As he expresses it, "something always goes to the 'kitty,'" whose remorseless maw will inevitably break the outsider if he plays the game long enough. The little commission charged for turning deals on the stock exchange or grain market is the equivalent of the amount that is paid to the "kitty" in a gambling game. This amount, trivial as it is, constitutes terrific odds against the man who is playing the game from the outside. It is the fleece of which the lamb must inevitably be shorn in time.

As an illustration of the readiness with which some doctors can be induced to go into wild cat schemes, a case which occurred in Chicago some months ago is a pertinent illustration.

As stated in the daily press, the particulars were as follows: A highly respectable gentleman, who practises medicine incidentally and poses as a moral educator generally, made complaint against certain race track gamblers, alleging that they had swindled him out of five thousand dollars. The swindling was conducted as follows: The doctor was informed that the gamblers had a "sure thing" on the races. This was to consist in tapping the wires over which returns were made to the various pool rooms of the city. Private and preliminary information as to the results of the races was thus to be obtained in ample time to enable the coworkers in the scheme to place bets. There was no wire tapping done. The doctor was shown a room in which fake telegraphic instruments had been installed, and gave up his money like the lamb that he was. The moral of this story is that it is better to be plucked as a lamb, and done with it, than to form a copartnership with wolves for the purpose of shearing other lambs. There should be honesty among lambs as well as among thieves.

It is high time that the physician should regard the individual who enters his office with a specious scheme for investment with promises of large re-

turns as being on the average worthy of the same respect and treatment that would be accorded a pickpocket. Such promoters should be refused an audience primarily, and if they succeed in gaining an audience should be treated with the degree and kind of consideration they deserve.

G. FRANK LYDSTON.

THE TUBERCULOSIS PROBLEM AND MR. HENRY PHIPPS'S PHILANTHROPY.

It would indeed be ungracious on the part of the medical profession to let the recent gift of \$1,000,000 by Mr. Henry Phipps to the city of New York for the establishment of model tenement houses pass by unnoticed. Few American philanthropists have identified themselves so closely with the tuberculosis problem as has Mr. Henry Phipps, formerly of Pittsburgh, now of New York. As is well known, he established in Philadelphia that admirable institution for the study, prevention, and treatment of tuberculosis, known as the Henry Phipps Institute, which is under the able guidance of Dr. Lawrence F. Flick, the well known authority on tuberculosis.

The solution of the tuberculosis problem cannot be accomplished if all energies are centred in one direction only. There are to my mind five distinct branches to be followed to attain the one end. These are, first, the sanitary housing of the poor; second, the education of the masses regarding the prevention of tuberculosis; third, taking care of and isolating, as far as practicable, the advanced and hopeless cases; fourth, the establishment of sanatoria to cure the curable cases in adults and children; fifth, the thorough training of medical men in the early recognition of tuberculosis.

No matter how many sanatoria and special hospitals we may have for the treatment and care of the consumptive poor, as long as unhygienic and insanitary tenements exist, the education of the masses will be of little avail, and the filthy and crowded rooms with lack of air and light will only help to create a continued supply of consumptives to fill the sanatoria and special hospitals.

By the establishment of the Institution for the Study, Prevention, and Treatment of Tuberculosis in Philadelphia, Mr. Phipps, with a sagacity which cannot be too much admired, has given to that and

other cities an example of how the four last mentioned methods should be accomplished; the education of the masses, the care and isolation of the hopeless cases, curing the curables, and offering facilities to medical men for a thorough study of tuberculosis and its early recognition.

Through his gift to New York, the other day, Mr. Phipps pointed out the first and primary factor in the solution of the tuberculosis problem, to provide sanitary homes for the poor. He thus struck at the very first evil responsible for the spread of tuberculosis among the poor, for it is obvious that the education of the masses regarding the prevention of tuberculosis by teaching to them the necessity of fresh air, sunlight, and clean environments cannot bring forth good results so long as they are compelled to live in insanitary tenements with insufficient light and air and lack of hygienic necessities.

To make no mistake in his noble enterprise, Mr. Phipps has called to his aid experienced sanitarians and philanthropists, among whom are such men as Isidor Straus, John W. Arbuckle, Dr. E. R. L. Gould, W. S. Hawk, Charles A. Moore, George E. Gordon, John S. Phipps, Charles Stewart Smith, Robert W. de Forest, Alfred T. White, Myles Tierney, and Charles S. Brown. As a result of a preliminary meeting of these gentlemen a board of trustees has been formed to which Mayor McClellan's name has been added in an ex officio capacity.

There is perhaps no class of people who can appreciate Mr. Phipps's gift better than the medical men of New York, particularly those who have had occasion to become familiar with the condition of the old fashioned tenement houses and the sufferings which the gloomy surroundings and lack of air and light produced among the unfortunate sufferers from tuberculosis and other diseases. What a boon it will be to the many scrofulous and anæmic children, and how much less of infantile suffering there will be in these buildings in the hot summer, for to these model tenement houses there will be attached playgrounds for the children and breathing spaces for the adults.

Let us hope that Mr. Phipps's generous gift will be an impulse to other philanthropists to do likewise; that every large city in the United States may

have an institution for the study, prevention, and cure of tuberculosis, such as Mr. Phipps has given to Philadelphia; and that model tenement houses will be created through private and public philanthropy everywhere in the United States where there are men, women, and children who must now live like cliff dwellers or in hovels unfit for human habitation.

S. A. KNOPF.

PRECOCIOUS SEXUAL DEVELOPMENT.

Perhaps one of the most remarkable cases of sexual precocity recently observed is one recorded by Stein (*Deutsche medizinische Wochenschrift*, 1904, No. 35; *Berliner klinische Wochenschrift*, December 12th). A female child six months old menstruated regularly, synchronously with the mother. Its breasts and genitals were unusually developed, and the latter were provided with hairs two thirds of an inch long. No internal examination was made.

A DIRECTORY OF TUBERCULOSIS INSTITUTIONS.

A very useful publication entitled *A Directory of Institutions and Societies Dealing with Tuberculosis in the United States and Canada* has just been issued by the Charity Organization Society of the City of New York. It has been compiled by Lilian Brandt, the society's statistician. Such a book cannot but be frequently of use to medical men.

THE PAMPERED STOMACH.

When we see an otherwise sensible man take for his entire luncheon day after day that which would not satisfy a cat, those of us who are under the impression that the organs of the body were made to work, and not to loaf, are apt to reflect that many men do a deal of worrying over things that Nature is perfectly competent to take care of.

Obituary.

THOMAS H. MANLEY, M. D.,

OF NEW YORK.

The fact that such an uncommonly robust man as Dr. Manley should have died at a comparatively early age will come as a surprise to our readers. They will recall his ardent enthusiasm in the pursuit of professional investigation, his devotion to the improvement of surgery, and the assiduity with which he recorded the results of his observations. His loyalty to the best interests of the profession, always directed along the most ethical paths, will long be remembered, and it will serve as a stimulus to many a young man in need of encouragement.

News Items.

Society Meetings for the Coming Week:

MONDAY, January 23rd.—Medical Society of the County of New York; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, January 24th.—Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Va., Academy of Medicine and Surgery; New York Medical Union (private).

WEDNESDAY, January 25th.—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; New York Dermatological Society (private); American Microscopical Society of the City of New York; Philadelphia County Medical Society; Auburn, N. Y., City Medical Association; Berkshire, Mass., District Medical Society (Pittsfield).

THURSDAY, January 26th.—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Mass., Society for Medical Improvement (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.; New York Celtic Medical Society.

FRIDAY, January 27th.—New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, January 28th.—New York Medical and Surgical Society (private; annual); Harvard Medical Society, New York (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 12, 1905:

	January 7.		January 12.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	122	11	189	6
Diphtheria and croup	300	45	307	43
Scarlet fever	227	22	281	17
Smallpox	3	..
Chickenpox	138	..	202	..
Tuberculosis	282	168	338	160
Typhoid fever	47	11	56	9
Cerebrospinal meningitis	24	..	26
	1,116	281	1,376	261

Increasing Work of the Morgue.—Over 10,000 bodies were received at the New York Morgue in 1904. In 1903 about 8,000 bodies were cared for, while in 1902 the number was only about 5,000.

Testimonial to Dr. Sheil.—Members of the medical staff connected with the health department of the Bronx have presented a beautiful loving cup to Dr. Gerald Sheil, assistant sanitary inspector for the borough, in appreciation of his courteous treatment of those under his direction.

The Manhattan Eye, Ear, and Throat Hospital.—Plans for the new home for the Manhattan Eye, Ear, and Throat Hospital, which is estimated to cost \$600,000, have been filed. The building is to be a nine story fireproof structure, containing every modern convenience, with two wings equipped with sun parlors. It will be built at Nos. 208 to 216 East Sixty-fourth Street.

City Medical Examiner Wanted.—The Civil Service Commission held a hearing on January 13th on the application of Comptroller Grout, for establishing the position of medical examiner in his department in the exempt class. Mr. Grout is anxious to have a doctor attached to his department who can devote his time in examining claims against the city for personal injuries. The commission did not take any action. President Coler said that the action of the commission on Mr. Grout's application would be guided by the ruling of the State Civil Service Board in several similar applications, which are now pending before them.

A New Morgue for Brooklyn.—Brooklyn's new morgue, which has been built on Washington Street, and adjoins the old building, will be opened on Monday next, January 23rd. The building is 40 by 50 feet, is a one story structure, and cost \$26,000. The new morgue has all modern improvements, and is provided with the most approved refrigerating system. Each slab, on which bodies will lie, is separate, and there are thoroughly equipped autopsy and undertaking rooms in the building. The old morgue has been renovated and the interior remodeled. There is a chapel and reception room, and living quarters for the keeper in the old building.

A New Red Cross Hospital, to take the place of the structure now on West Eighty-second Street, will probably be erected on One Hundred and Ninetieth Street, on the heights overlooking Fort George. William T. Wardwell, president of the New York Red Cross, has given \$100,000 for a site. John S. Huyler has presented the bricks necessary for the erection of the buildings, and an anonymous Philadelphia donor has started an endowment fund with a gift of \$3,000. The present hospital has accommodations for eighteen patients, but the new building will be able to care for one hundred. Instead of wards, the interior will be made up in small rooms, with movable walls, so that they can be raised to form a large hall. The new building is expected to cost \$150,000, exclusive of land, and to have an endowment fund of \$100,000.

The Manuel Garcia Centenary Jubilee Fund.—At a meeting of the allied committees representing the American Laryngological Association, the American Laryngological, Rhinological, and Otolological Society, and the section in laryngology of the New York Academy of Medicine, it was voted to appeal to laryngologists throughout the country for contributions not exceeding five dollars each for the Garcia Fund. Payment should be made before February 15th to either Dr. D. Bryson Delavan, 1 East Thirty-third Street; Dr. M. D. Lederman, 58 East Seventy-fifth Street; or Dr. Harmon Smith, 44 West Forty-ninth Street, representing the academy section; Dr. R. C. Myles, 48 West Thirty-sixth Street, representing the American Laryngological, Rhinological, and Otolological Society; or Dr. J. E. Newcomb, 118 West Sixty-ninth Street, representing the American Laryngological Association.

The Medical Society of the County of New York.—A stated meeting will be held on Mon-

day, January 23rd, at eight p. m. Programme: Minutes of the last meeting; report of the Comitia Minora; presentation of certificates of membership; paper, A Century's Criminal Alliance Between Quacks and Newspapers, illustrated with stereopticon views taken from typical quack advertisements of the last one hundred years, contained in Mr. Andrews's private collection of American newspapers, by Champe S. Andrews, counsel to the society. Discussion by the Honorable Edward E. Ommen, City Magistrate; Theodore Sutro, retiring president of the Society of Medical Jurisprudence; Robert C. Taylor, Assistant District Attorney, New York county; new business; adjournment. Meetings of this society in 1905 will be held on February 27th, March 27th, April 24th, and May 22nd.

The New York Academy of Medicine.—The section in genitourinary diseases will meet on Wednesday, January 18th, at 8.15 p. m. Prompt attendance is earnestly and respectfully requested. Order: Election of officers; presentation and report of cases: (a) Excision of Penis and Inguinal Glands (both sides) for Epithelioma, by F. Tilden Brown, M. D.; (b) Pseudohermaphroditism (female type), by George E. Brewer, M. D.; (c) Suprapubic Prostatectomy Complicated by Vesical Calculi, by Howard Lilienthal, M. D.; (d) Nitrate of Silver Burn of Urethra Followed by Sloughing (preliminary report with patient and specimen), by Victor C. Pedersen, M. D.; presentation of specimens and instruments; paper, Genitourinary Tuberculosis, by Robert H. Greene, M. D.; discussion by Dr. Blake, Dr. Harlow Brooks, Dr. Cabot, Dr. Erdmann, and Dr. Squier. James Pedersen, M. D., chairman; E. L. Keyes, Jr., M. D., secretary, 109 East Thirty-fourth Street.

The section in laryngology and rhinology will meet on Wednesday, January 25th, at 8.15 p. m. Order: Presentation of cases; paper, The Equilibrium Between Infection and Immunity as Illustrated in the Tonsillar Crypt, by Jonathan Wright, M. D.; specimens and new instruments; Unusually Large Polypus from the Nasopharynx, by J. Leshure, M. D.; executive session. Lewis A. Coffin, M. D., chairman; Lee Maidment Hurd, M. D., secretary, 15 East Forty-eighth Street.

The section in obstetrics and gynecology will meet on Thursday, January 26th, at 8.15 p. m. Order: Election of officers; presentation of specimens; *paper, After-Treatment of Abdominal Section, by Daniel H. Craig, M. D., of Boston. A. Palmer Dudley, M. D., chairman; Charles F. Adams, M. D., secretary, 104 West Seventy-third Street.

The Sydenham Hospital.—The newly elected board of directors of the Sydenham Hospital, located on East One Hundred and Sixteenth Street, has just received for hospital purposes as a New Year gift, from Isaac Guggenheim, \$1,000. Mr. Guggenheim has also made a generous offer further to aid the hospital and its training school by giving monthly an amount of money equal to such sums as the board of directors succeed in

* Paper deferred from December meeting of the section. Dr. Craig was unable to be present.

raising each month through donations or voluntary contributions. This offer holds good up to the sum of \$10,000 a year. The recent benefit entertainment at the New York Theatre netted the sum of \$1,500 for the hospital. Announcement of Mr. Guggenheim's liberal offer and also the result of the theatrical benefit was made known to the directors at their meeting last Monday evening. The Sydenham Hospital was started two years ago and has been very successful. At first only one building was used for its dispensary, but the work and the needs of the hospital grew so very rapidly that to-day three buildings are thoroughly equipped for this purpose. After next May the two adjoining buildings will be added to the hospital plant in order to provide more room for nurses and private patients, and when complete the hospital will occupy five buildings, Nos. 339 to 347 East One Hundred and Sixteenth Street. The last report of the hospital shows that more than ten thousand treatments were given at the hospital dispensary during the past year and six thousand hospital days were free in the hospital. The congested population in this part of the city has attracted the attention of Mr. Guggenheim and other members of the board to the absolute necessity for an institution of this character in this quarter of the city, and for this reason Mr. Guggenheim's gift is gratefully received by the hospital, and the directors are now hard at work attempting to raise sufficient funds to take advantage of Mr. Guggenheim's offer. William I. Spiegelberg is president of the hospital. Lewis M. Bloomingdale, of 78 Fifth Avenue, is the treasurer, and Sanford Simons is secretary. Among the directors are: Joseph P. Day, who is vice-president, Samuel Strasbourger, Isaac Guggenheim, N. Taylor Philips, and William Bretter.

PHILADELPHIA.

Personal.—Dr. Francis D. Patterson has been elected surgeon to the Howard Hospital, vice Dr. Charles H. Frazier, resigned.

Dr. Milton J. Greenman was elected director of the Wistar Institute of Anatomy on January 11th, vice Dr. Horace Jayne, resigned.

The Philadelphia Polyclinic Hospital, during the month of December, treated the following cases: Patients admitted to house, 115; patients discharged, 98; new patients treated in dispensary, 1,447; total visits to dispensary, 7,667; accident ward, 601.

Philadelphia County Medical Society.—The following was the programme of the Philadelphia County Medical Society for January 11th: Dr. Anna M. Fullerton (by invitation), Medical Experiences in India; Dr. B. Franklin Royer, The Antitoxine Treatment of Diphtheria; Dr. M. Graham Tull, An Unusually Severe Case of Acute Chorea Treated Successfully with Apomorphine.

Beri-Beri at Marcus Hook.—The American bark, *Abby Palmer*, arrived at the quarantine station at Marcus Hook on January 8th. Two members of the crew, an Englishman and a

Swede, were found by the quarantine officer, Dr. Henry L. Horning, to be suffering from beri-beri. They were both isolated in the quarantine hospital, and the other members of the crew were placed in the detention ward. The ship, which hailed from Kaanapali, Hawaiian Islands, was fumigated.

Section in Otolaryngology, College of Physicians.—The following was the programme of the section in otology and laryngology of the College of Physicians on January 18th:

Dr. G. M. Marshall, An Extensive Lupus Ulceration of the Nose; presentation of case; Dr. Walter Roberts, The Mastoid Incision, with exhibition of a case; Dr. E. L. Vansant, A Syringe for the Treatment of Diseases of the Accessory Sinuses; Dr. D. Braden Kyle, Demonstration of the Method of Teaching by Means of the Stereopticon, and A Case of Complete Adhesion of the Vocal Bands.

For a Portrait of Dr. William Osler.—A committee of graduates of the medical department of the University of Pennsylvania, of which Dr. Charles H. Frazier is treasurer, is engaged in collecting funds from physicians who studied at the University of Pennsylvania between 1884 and 1889, for the purpose of having a life-sized portrait of Dr. William Osler painted. The portrait will be presented to the medical department of the university.

The Annual Meeting of the Medical Club was held on Friday evening, January 13th. The following officers were elected: President, Dr. Roland G. Curtin; first vice-president, Dr. Wharton Sinkler; second vice-president, Dr. Thomas G. Potter; secretary, Dr. J. Gurney Taylor; treasurer, Dr. Lewis H. Adler, Jr.; board of governors, Dr. E. E. Montgomery, Dr. Ernest La Place, Dr. H. H. Whitcomb, Dr. Walter L. Pyle, and Dr. Alexander McAlister.

Death.—Dr. Josiah Peltz died suddenly at his home, 608 North Seventeenth Street, on January 13th, aged 62 years. Dr. Peltz was born in Chester County, Pa.; he was educated in the public and private schools of the vicinity and graduated from the medical department of the University of Pennsylvania in 1865. He was a member of the Philadelphia County Medical Society and of the Medical Society of the State of Pennsylvania. Following an attack of influenza Dr. Peltz developed valvular heart disease, from which he died.

Officers of the American Philosophical Society.—At the annual meeting of the American Philosophical Society, held at the headquarters of the society, 104 South Fifth Street, on January 6th, the following officers were elected:

President, Edgar F. Smith; vice-presidents, George F. Barker, William B. Scott, Simon Newcomb; secretaries, I. Minis Hays, Edwin G. Conklin, Arthur W. Goodspeed, Morris Jastrow, Jr.; treasurer, Henry La Barre Jayne; curators, Charles L. Doolittle, William P. Wilson, Albert H. Smyth; councillors, George F. Edmunds, James T. Mitchell, Joseph Wharton, Dr. William W. Keen. Dr. I. Minis Hays was nominated for librarian for the ensuing year.

Philadelphia Pædiatric Society.—The following was the programme of the Philadelphia Pædiatric Society for Tuesday, January 10th: Dr. D. J.

Milton Miller presented a Patient with Intestinal Atony; Dr. J. P. Crozier Griffith reported cases and exhibited specimens: (1) Umbilical Cord Hernia; (2), Congenital Stenosis of the Bile Duct; Dr. David L. Edsall and Dr. C. W. Miller read a paper on The Dietetic Use of Legume Flour, Particularly in Atrophic Infants; with Observations on Absorption and Metabolism. The retiring president delivered the annual address.

Scientific Society Meetings for the Week Ending January 28, 1905.—Monday, January 23rd, Mineralogical and Geological Section, Academy of Natural Sciences. Tuesday, January 24th, Northwest Medical Society; Philadelphia Neurological Society. Wednesday, January 25th, Philadelphia County Medical Society. Thursday, January 26th, Pathological Society; Entomological Section, Academy of Natural Sciences. Friday, January 27th, South Branch, Philadelphia County Medical Society; Northern Medical Association.

The Health of the City.—The following cases of transmissible disease were reported to the Bureau of Health for the week ending January 7, 1905:

	Cases.	Deaths.
Typhoid fever.....	99	8
Scarlet fever.....	64	2
Chickenpox.....	90	0
Diphtheria.....	98	15
Measles.....	15	1
Whooping cough.....	6	1
Tuberculosis of the lungs.....	122	64
Pneumonia.....	62	62
Erysipelas.....	15	2
Puerperal fever.....	1	0

The total death rate for the week was 478, in an estimated population of 1,438,318, corresponding to an annual death rate of 17.28 per 1,000 population. The infant mortality was 89; 73 under one year and 16 between one and two years. There were 36 still births; 22 males and 14 females. The following deaths from other transmissible diseases were reported: Tuberculosis other than tuberculosis of the lungs, 3; diarrhoea and enteritis under two years, 14. The meteorological report of the weather bureau shows another week of variable temperatures and cloudy or rainy weather; 1.36 inches of rain or snow having fallen. On January 4th and 5th the minimum temperature was 16°.

Pathological Society.—The annual exhibition meeting of the Pathological Society, which was held on January 11th and 12th, was, as usual, very successful. Many specimens of an instructive and interesting nature were shown. The exhibition meetings, which have been held by this society annually for the past few years, give an excellent opportunity for the exhibition of series of specimens or particularly interesting individual specimens in a way that conveys more to the observer than the ordinary method of showing such specimens at a regular meeting of the society. The exhibitor is able to explain his work to small groups of interested spectators and the spectator is able to examine closely such specimens as interest him and may ask pertinent questions. This year the society inaugurated a new feature by having between 8.30 and 9.30, on the two evenings devoted to the meeting, short dem-

onstrations by exhibitors of specimens forming consecutive series. The list of these demonstrations follows:

Wednesday evening, January 11th: Dr. J. McFarland, How Metastasis Occurs in Malignant Tumors; Dr. M. H. Cryer, The Variations in the Frontal Sinuses; Dr. W. T. Longcope, A Series of Aneurysms; Dr. W. E. Robertson, A Series of Hearts and Aneurysms; Dr. R. C. Rosenberger, Cardiac Pathology; Dr. B. M. Anspach, Gynaecological Pathology.

Thursday evening, January 12th: Dr. A. J. Smith, Structure of the Distoma Pulmonale; Dr. Funke, Diseases of the Alimentary Canal; Dr. C. Y. White, Tuberculosis in Man and Lower Animals; Dr. C. H. Frazier, Tumors of Thyroid and Salivary Glands; Dr. A. F. Coca, Peculiar Bodies in Serum of Artificial Blisters on Syphilis Eruption (three cases); Dr. D. J. McCarthy, Cerebral Arteriosclerosis.

GENERAL

Dr. Charles H. Althaus, of Jersey City, has gone to the Bahamas for the winter, owing to the health of his wife.

Dr. M. Lampson has resigned from the staff of the City Hospital of Jersey City, after many years of service.

San Francisco Board of Health.—Dr. J. W. Ward has been unanimously reelected president of this board.

Cincinnati Board of Health.—Dr. J. W. Miller has been appointed by this board district physician in place of Dr. Muhlberg, who is leaving the city.

Dr. Charles H. Gumley, of Cincinnati, was severely injured on December 29th by being thrown from his carriage; among other injuries he sustained a fracture of the arm.

Emergency Hospital, Buffalo.—Dr. James T. Gallagher has been appointed to succeed, as superintendent of this hospital, Dr. John H. Prior, who has resigned after long and faithful service.

Wisconsin Scholarship in Bacteriology.—Dr. Thomas W. Tormey, of Madison, Wis., has received the \$400 fellowship in bacteriology which was established recently by Dr. Gustav A. Kletzsch, of Milwaukee.

Georgia State Board of Medical Examiners.—Dr. F. M. Ridley, of La Grange, and Dr. W. D. Travis, of Covington, have been named by Governor Terrell to be members of this board for a term of three years, dating from January 7th.

The Warren County, N. Y., Medical Association elected the following officers on January 11th: President, Dr. William J. Tunt; vice-president, Dr. W. R. Keyes; secretary and treasurer, Dr. Fred G. Fielding.

Grace Hospital, New Haven, Conn.—This institution is the recipient of a gift of \$15,000 from an unknown donor to be used for the enlargement of the nurses' dormitory, the work on which will be started this spring.

Academy of Medicine, Milwaukee.—The following officers of this academy were elected on January 7th: President, Dr. T. J. Beattie; vice-president, Dr. George Gray; treasurer, Dr. C.

Lester Hall; secretary, Dr. George B. Worberg; censor, Dr. W. E. Montgomery.

Dinner to Minneapolis City Physician.—The city physician of Minneapolis, Dr. George E. Ricker, and Mrs. Ricker, were guests of honor at a dinner given at the city hospital on December 26th. A suit case and silk umbrella were presented to Dr. Ricker.

Madison County, Tenn., Medical Association.—This association has elected the following officers for the current year: President, Dr. H. D. Westmoreland, of Huntsville; vice-president, Dr. Claude Pettus, of Monrovia; secretary and treasurer, Dr. M. R. Moormann.

The Chattanooga and Hamilton County, Tenn., Medical Society, at its meeting held on January 6th, elected officers as follows: President, Dr. J. S. B. Woolford, of Highland Park; vice-president, Dr. J. W. Johnson; secretary, Dr. H. P. Larimore; treasurer, Dr. S. Y. Yarnell.

The Health Report of Connecticut for December, 1904.—The following cases of infectious disease were reported: Measles, 171; scarlet fever, 197; cerebrospinal fever, 18; diphtheria and croup, 195; whooping cough, 46; typhoid fever, 55; typhus fever, 1.

Corning, N. Y., Medical Association.—The election of officers of this association for the ensuing year has resulted as follows: President, Dr. H. A. Argue; vice-president, Dr. C. A. Carr; secretary, Dr. E. H. Hutton; treasurer, Dr. H. H. Hubbell.

Damage by Fires.—The residence of Dr. Henry M. Conkling in Summit, N. J., was practically destroyed by fire, entailing a loss of \$10,000.

Fire in the kitchen of the Royal Victoria Hospital, Montreal, on January 14th, caused over \$30,000 damage. None of the patients was injured.

Niagara County, N. Y., Medical Association.—The following officers were elected by this association on January 10th: President, Dr. Frank Guillemont, of Niagara Falls; vice-president, Dr. A. N. Moore, of Lockport; secretary, Dr. W. H. Potter, of Niagara Falls; treasurer, Dr. C. L. Preisch, of Lockport.

Minneapolis Health Department.—The medical personnel of the reorganized Minneapolis health department is as follows: Dr. F. E. Haynes, Dr. G. Daziel, and Dr. W. E. Leonard, medical inspectors; Dr. A. D. Meeds, chemist; Dr. A. A. Keys, veterinarian; Dr. J. Frank Corbett, bacteriologist.

Erie County, N. Y., Medical Society.—At the eighty-fourth annual meeting of this society, on January 10th, the following officers were elected: President, Dr. John D. McPherson; vice-president, Dr. A. H. Briggs; secretary, Dr. Franklin C. Gram; treasurer, Dr. D. C. Greene; board of censors, Dr. H. R. Hopkins, Dr. J. H. Grant, Dr. J. W. Potter, Dr. E. Wende, and Dr. F. E. Fonszak.

Milwaukee Medical Society.—At the annual meeting of the Milwaukee Medical Society, on

January 9th, Dr. H. B. Hitz was elected president. Other officers elected were: Secretary, Dr. H. E. Dearholt; librarian, Dr. A. W. Myers; vice-president, Dr. William Thorndyke; second vice-president, Dr. Oscar Chryslor; treasurer, Dr. R. C. Brown; curator, Dr. O. F. Fiedler; directors, Dr. A. J. Patsck, Dr. C. H. Stoddard, Dr. T. H. Hay, Dr. F. E. Walbridge, and Dr. G. E. Seaman.

The Incorporation of the American Medical Association.—On January 9th, Representative Dwight introduced in the house a bill to incorporate the American Medical Association. The following are the incorporators:

Robert M. O'Reilly, Presley M. Rixey, Walter Wyman, and Dr. E. H. Gregory, of St. Louis; Dr. Henry O. Marcy, of Boston; Dr. Nicholas Senn, of Chicago; George M. Sternberg, of Washington, D. C.; Dr. J. M. Matthews, of Louisville, Ky.; Dr. W. W. Keen, of Philadelphia; Dr. C. A. L. Reed, of Cincinnati; Dr. J. A. Wyeth, of New York; Dr. Frank Billings, of Chicago; Dr. J. H. Musser, of Philadelphia; Dr. T. J. Hoppel, of Trenton, N. J.; Dr. Miles F. Porter, of Fort Wayne, Ind.; Dr. E. E. Montgomery, of Philadelphia; Dr. W. W. Grout, of Denver; Dr. H. A. Johnson, of Washington, D. C.; Dr. A. L. Wright, of Burlington, Iowa; Dr. William H. Welch, of Baltimore; Dr. M. L. Harris, of Chicago; Dr. Phelps Morvel, of Atlantic City, N. J.; and Dr. Lewis S. McMurtry, of Louisville, Ky.

Statement of Mortality in Chicago for the Week Ending January 14, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Jan. 14, 1905.	Jan. 7, 1905.	Jan. 16, 1904.
Total deaths, all causes.....	542	542	566
Annual death rate, per 1,000.....	14.19	14.19	15.30
By sexes—			
Males.....	300	303	312
Females.....	242	239	254
By ages—			
Under 1 year.....	106	110	80
Between 1 and 5 years.....	39	48	49
Over 60 years.....	127	121	136
Important causes of death—			
Acute intestinal diseases.....	20	13	19
Apoplexy.....	24	12	15
Bright's disease.....	34	36	45
Bronchitis.....	24	24	21
Consumption.....	52	41	64
Cancer.....	23	18	19
Convulsions.....	16	6	9
Diphtheria.....	11	14	9
Heart diseases.....	32	47	50
Influenza.....	20	8	4
Measles.....	2	3	..
Nervous diseases.....	13	22	18
Pneumonia.....	108	135	117
Scarlet fever.....	2	3	4
Suicide.....	13	6	6
Smallpox.....	1
Typhoid fever.....	7	4	9
Violence (other than suicide).....	25	32	30
Whooping cough.....	4	7	1
All other causes.....	111	111	120

The hospital population continues to increase, chiefly by chronic cases driven to their shelter by the severe cold weather. The total deaths reported, 542, were the same in the aggregate as the previous week, but there were some curious changes in the individual causes of death. The following among the important show increases: Acute intestinal diseases, 7; apoplexy, 12; consumption, 11; cancer, 5; convulsions, 10; influenza, 12; suicide, 7; typhoid fever, 3. Important causes showing decreases were: Diphtheria, 3; heart disease, 15; nervous diseases, 9; pneumonia, 27; whooping cough, 3; measles and scarlet fever, 1 each.

LYON MEDICAL.

December 4, 1904.

Treatment of Cancer of the Neck of the Uterus by Vaginal

Vaginal Hysterectomy for Cancer of the Cervix Uteri.—The Condamins state that in cancer of the cervix the ganglions are invaded very slowly, that in cases operable through the vagina they are not involved in 80 per cent. of the cases and that when the parametrium has been invaded they present a proportion of 36 per cent. After the ganglions have become involved it is illusory to think of removing all the diseased tissue because the smaller ganglions are often degenerated and the cancer cells can be found not only in them but in the lymphatic tissues. The state of the parametrium should be accepted as the guide to the choice of operation. If this is not involved the vaginal method should be chosen. When it is involved the choice has to be made between a purely symptomatic treatment and an attempt to remove the disease through a laparotomy.

1. Development of Cancer in Animals from Human Cancer Juice Without Anatomical Elements.

By M. MAYET.

2. A Case of Infantile Osteomalacia.

1. Development of Cancer in Animals. Mayet has succeeded in producing cancer in rats from the introduction of human cancer juice.

2. Infantile Osteomalacia.—Berard and Nordmann report a case of osteomalacia in a female child 7 years old. The first symptoms appeared at the age of 18 months. At 4 years the child complained of pain in the limbs. At 5 years the legs were a little twisted. When seen, the deformations were multiple, throughout the body. The patient died two months later. The details of the autopsy are too long to reproduce.

December 18, 1904.

1. Intoxication with Gas, By Dr. ETIENNE MARTIN.

2. Sterilization of Basins Intended for Use in Surgical Operations or for Dressings,

By Dr. ADENOT and Mr. PERROY.

1. Intoxication With Gas.—Martin discusses the more frequent modes of poisoning and considers illuminating gas less dangerous than the products of combustion in stoves and furnaces. The cadaveric signs after death are very inconstant. Finally he considers how it may sometimes be possible to determine whether a person thus suffocated is the victim of an accident or is a suicide.

2. Sterilization of Basins.—Adenot and Perroy recommend as the easiest and surest method of sterilizing basins of porcelain, glass, etc., a repeated washing with soap, or carbonate of sodium, scrubbing with a 1 to 5,000 solution of corrosive sublimate, and finally rinsing with boiled or sterilized water. In case of septic contamination the strength of the solution should be increased, or it

should be allowed to remain for a longer time in contact, before rinsing.

PRESSE MEDICALE.

November 30, 1904.

1. Injections of Cold Paraffin.

By BROECAERT.

2. Mechanical Purification of Milk.

By DIFFLOTH.

1. Injections of Cold Paraffin.—Broecaert describes an instrument he has invented for injecting paraffin into the tissues. It consists of a metal syringe 9 cm. long, with a capacity of 1 c.c., needles of various sizes, and a piston 1½ cm. long, to which is attached at right angles a pair of forceps handles 20 cm. long, sufficiently large to enable considerable force to be exerted in making the injection. The results he has obtained by the injection of cold paraffin into the tissues of the nose seem at present to be good, but he acknowledges that his experience has been too recent for a definite judgment to be made as yet.

2. Mechanical Purification of Milk.—Diffloth classes under the name purification the modification of milk by mechanical processes, such as filtration and centrifugation, under rectification the modifications obtained by heat and cold, pasteurization, sterilization, condensation, etc., under conservation that obtained from the action of chemical agents. He finds that filtration does not change the chemical composition of the milk or its digestibility and was unable to demonstrate that it exerted any preservative action. Centrifugation he found did not diminish the number of bacteria in milk.

December 3, 1904.

1. Anatomy and Pathological Physiology of Liver Disease Due to Cardiac Disease,

By E. GÉRAUDEL.

2. The Nascent State of Drugs,

By M. FRENKEL.

3. The Constituents of Urine. The Alimentary Origin of Urinary Excreta. The Mineral Constituents,

By M. and H. LABBÉ

1. Liver Disease of Cardiac Origin.—Géraudel describes practically no changes in the portal zone, integrity or slight hypertrophy of the cells with no dilatation of the capillaries, while in the upper part of the liver he found a total dystrophy of the parenchyma, trabecular dystrophy with changes in the cells, and capillary dystrophy with ectasia and rupture, which give rise to infarcts.

2. The Nascent State of Drugs.—Frenkel states that oxidation in the body is generally by means of atomic oxygen and that the nascent state of a simple substance is confounded with its atomic state.

3. The Constituents of the Urine.—The Labbés consider the elimination of chlorides, phosphorus, and sulphur by means of the urine extensively, that of other salts, carbonates, oxalates, etc., more briefly. The origin of all is traced to alimentation, and their excretion found to be proportional to their ingestion. The consideration of the quantities of chlorides, phosphates, and sulphates excreted gives a means of appreciating the quantity and quality of the alimentation.

ZENTRALBLATT FUER GYNAEKOLOGIE

November 19, 1904.

1. Results After Anterior Vaginoutrine Section,

By H. v. BARDELEBEN.

2. Hebotomy,

By G. LEOPOLD.

3. Symphyseotomy,

By D. V. VELITS.

4. Technics of Lateral Section,

By L. GIGLI.

5. Prolapse of Omentum in a Laparotomy Scar Eight Years After Operation,

By WESTPHAL.

6. Suture of Fresh Perineal Tears,

By H. ROSE.

7. Model of Fœtal Skull,

By G. BURCKHARD.

1. Anterior Vaginoutrine Section.—Von Bardeleben found very good results following anterior vaginal hysterotomy, most of them for eclampsia. In five cases, the vaginal portion of the cervix was wholly restored, in two cases there were deep scars and in only one was there a deep laceration. There were no uterine displacements and there had been no hæmorrhages or uterine discharge. Bardeleben prefers the operation to any method of cervical dilatation.

2. Hebotomy.—Leopold reports five cases of hebotomy performed after the method of Gigli and Doederlein. Three of the children survived and the results for the mother were good in all instances.

3. Symphyseotomy.—Velits discusses the changes which have taken place in the minds of obstetricians concerning this operation and reports three cases of his own, in which he saw subsequently eight births. He agrees with Zweifel's assertion that the operation has the advantage of affording easy births for the women later on account of the roomier and more easily dilatable pelvis.

4. Technics of Lateral Section.—Gigli vigorously defends his priority to the originality of the operation, so frequently called "hebotomy" by the Germans. As to the technics, he says that the incision must be made outside of the articulation of the symphysis, and must be made outside of the insertion of the pubovesical ligament toward the symphysis.

6. Immediate Perineal Repair.—Rose advises the suture of vaginal and perineal wounds before the expulsion of the placenta. He places the patient in the side position and ties only the first half of the surgical knot, so that it shall not give way during the placental birth. After this event, the knot is tightly tied. His results with this method have been excellent.

November 26, 1904.

1. Opitz's "Pregnancy Glands,"

By M. SCHWAB.

2. Symptomatology of Movable Retroflexion of the Uterus,

By W. NACKE.

3. Removal from the Bladder of a Goosequill Surrounded by Calculi,

By P. VON KUBINYI.

4. Bilateral Mastitis During Pregnancy Following Impetiginous Eczema of the Nipples,

By A. CALMANN.

5. Amputation of the Inverted Uterus,

By E. FALK.

1. Opitz's "Pregnancy Glands."—Schwab asserts the glands described by Opitz as being characteristically found in the endometrium of pregnancy, are present not only in pregnancy as a result of the nidation of the ovum, but can also be evoked by the congestion of menstruation. In forty-one cases, he found Opitz's glands five times, four times in instances in which a previous pregnancy could be absolutely excluded.

2. Symptoms of Retroflexion.—Nacke analyzed 265 cases of retroflexion of the uterus. Only thirty-seven of these patients, fourteen per cent., had no symptoms. Sixty-two others had to be withdrawn from analysis because their symptoms were not referable to the displacement. The author believes that retroflexion produces symptoms only when the uterus is enlarged or irritated by physiological or pathological processes. If the pelvic contents and the appendages are normal, symptoms will be produced, perhaps, by minute nervous changes such as are called forth by the atrophic chronic parametritis as described by Freund.

3. Vesical Calculus.—Kubinyi describes the case of a woman who attempted to catheterize herself with a goosequill which broke during the procedure. A calculus developed about the fragment which the author removed with a bullet forceps, after dilatation of the urethra. Both the bladder and the urethra appeared to be anæsthetic, which the author refers to an affection of the cauda equina or the medullary cone.

5. Amputation of Inverted Uterus.—Falk removed an irreducibly inverted puerperal uterus by a horizontal incision in the anterior vaginal wall. He was enabled, after drawing the uterus forward, to ligate the broad ligament and the appendages without difficulty and without hæmorrhage. By continuing his incision around into the posterior wall, the uterus was then removed. The recovery of the patient was uneventful.

December 31, 1904.

1. Dangerous Hæmorrhage from the Urinary Tract During Pregnancy,

By P. VON KUBINYI.

2. Death During Labor from a Rupture of a Mesenteric Artery,

By JACOBY.

3. Local Anæsthesia with Eucaïne and Adrenalin,

By H. FREUND.

4. Abdominal Hernia of a Pregnant Uterus,

By A. ROSNER.

1. Hæmorrhage from the Urinary Tract.—Kubinyi narrates the case of a woman in the eighth month of pregnancy who passed bloody urine after lifting a heavy load. This was followed by urinary retention with continued distention of the bladder. The bladder could be emptied and washed out only after dilatation of the urethra and the introduction of the finger. Recovery followed. The author assumes a ruptured varicose vein in the bladder as the cause of the bleeding.

2. Intrapartum Death from Hæmorrhage.—Jacoby reports the case of a twenty-five year old

multipara who went into collapse shortly after the sudden visit of her husband with whom she had not been living. She had simultaneous abdominal pain. She recovered from this and shortly afterward began to have labor pains (in the seventh month), accompanied by a second collapse, from which the patient died. The autopsy showed an intraabdominal hæmorrhage probably due to a ruptured vein in the region of the mesocolon. No arteriosclerosis or syphilis was demonstrable. It could not be shown that the hæmorrhage was due to external violence. The case presents many features of forensic interest.

3. Local Anæsthesia.—Freund recommends for vaginal operations a local anæsthesia induced by eucaine and adrenalin. He uses the mixture by employing nine parts of a one per cent. solution of Beta-eucaine, and one part of a one to 1,000 solution of adrenalin. The solution is slowly injected and anæsthesia lasts from five to fifteen minutes. The solution can be made more astringent by increasing the proportion of adrenalin.

4. Hernia Abdominalis Uteri Gravidæ.—Rosner reports this rare anomaly in a woman who had had a right ventral hernia for some years. At term, a Porro's operation was successfully performed, the child, however, dying the same day.

BERLINER KLINISCHE WOCHENSCHRIFT.

November 28, 1904.

1. Carbonic Monoxide Poisoning.
By F. STRASSMANN and A. SCHULZ.
2. Diagnostic Significance of Disappearing Paralysis of the Vocal Cords,
By W. BERENT.
3. Mode of Infection in Pulmonary Tuberculosis,
By M. WASSERMANN.
4. Acute Articular Rheumatism in Children (*Concluded*),
By A. BAGINSKY.
5. International Congress in St. Louis, By CARL BECK.

2. Paralysis of the Vocal Cords.—Berent narrates a case in which a diagnosis of aneurysm of the aorta was made with a paralysis of the right recurrent nerve. Later the paralysis involved the adductor muscles. The diagnosis was questioned but was finally adhered to on account of the disappearance of the vocal cord paralysis. The autopsy confirmed the diagnosis and showed that the paralysis had changed, on account of the filling of the aneurysmal sac with blood clot, thus bringing about a modification of the signs produced by pressure.

3. Pulmonary Tuberculosis.—Wassermann reports several cases to show that pulmonary tuberculosis originates in the apex by way of the lymph channels in the neck, which transmit the infection to the parietal pleura of the upper part of the chest, which forms adhesions with the visceral pleura. The appearance of stitches in the apical region is significant of this mode of infection. The author condemns massage of enlarged cervical glands, and believes infection on the

right side more frequent on account of the greater mobility of that side of the chest.

December 5, 1904.

1. Diagnosis and Treatment of Cardiospastic Dilatation of the Œsophagus,
By H. STRAUSS.
2. Chromophore Zones in Vital Blood Staining,
By H. ROSIN and E. BIBERGEIL.
3. Family Tabes Dorsalis,
By W. CRONER.
4. Treatment of Blood Diseases with the Röntgen Ray,
By R. MILCHNER and M. MOSSE.
5. Cure of Œsophageal Stricture with Sounds,
By WADSACK.
6. Metabolism in Convalescence After Chronic Malnutrition,
By F. RICHTER.
7. Experiments on Development of Lymphocyte Exudates,
By A. WOLFF and A. VON TORDAY.
8. Diagnosis of Renal Tuberculosis,
By R. MILCHNER.
9. Senator's Influence in Medical Jurisprudence,
By STRAUCH.
10. Senator's Work on Skin Function, Skin Diseases, and Syphilis,
By R. LEDERMANN.

1. Cardiospastic Dilatation of the Œsophagus.—Strauss reports a case of Œsophageal dilatation at the upper end of which, at autopsy, a carcinoma was found. In a second case, the author brought relief to a patient by means of the Miculicz pressure probe, although the dilatation was, of course, not affected. The author speaks of the newer refined methods of diagnosis of this condition and of the possibilities of treatment which can be achieved by their aid.

2. Chromophore Zones.—Rosin and Bibergeil note that when methylene blue and methylene azure are used for vital blood stains, before the nuclear stain is completed, a very deep stain is developed in the erythrocytes usually not stainable, and especially those which surround the white blood cells. The phenomenon is a temporary one, and is seen in normal and in pathological blood.

3. Family Tabes Dorsalis.—Croner speaks of two series of cases of locomotor ataxia, in each of which three brothers were affected. In the first group, syphilis had been demonstrated, in the second it was positively known as to only one of the brothers. Croner believes that, although syphilis plays a very important rôle in the production of locomotor ataxia, other ætiological factors must also exist.

7. Lymphocyte Exudates.—Wolff and Torday give these as the results of their experiments. It is possible to bring about an exudate of lymphocytes in mice and guinea pigs by the injection of tetanus and diphtheria toxins, which last for one or two hours after the injection. According to the authors, these results prove the theory of active lymphocytosis. Lymphocytosis and leucocytosis run different courses in different animals. The mouse, for instance, has a tendency toward lymphocytosis which appears in this species even when the same material would evoke a polynucleosis in guinea pigs.

8. Renal Tuberculosis.—Milchner narrates the case of a girl, eleven years of age, in whom

there were a purulent discharge and hæmorrhage from the left kidney, which was enlarged and sensitive and had diminished function. The urine contained acid-fast bacilli. The diagnosis of tuberculosis of the kidney was made and the organ was removed. There was no tuberculosis, but a hydronephrosis with a kink in the ureter. The acid-fast bacilli proved to be smegma bacilli. The author insists upon the necessity of inoculation experiments in similar cases to prove the correctness or falsity of the diagnosis.

December 12, 1904.

1. Cure and Latency of Diabetes Mellitus, By H. LEO.
2. Can "Internal Disinfection" Be Induced by "Griserin"? By PETRUSCHKY.
3. Chronic Poisoning of the Eye with Lead, By L. LEWIN.
4. Physical Action of Solutions in the Human Stomach, By P. SOMMERFELD and H. ROEDER.
5. Psyche and Psychosis (*To be continued*), By P. KRONTHAL.

1. **Cure and Latency of Diabetes.**—Leo demands, as a *sine qua non*, that patients alleged to be cured of diabetes shall have no sugar in the urine by any test after being placed upon a strong starchy diet, whereas during a rigid diet there was previously no sugar to be found. He cites a case to show how careful one must be in asserting a patient to be cured of diabetes, in the instance of a man who appeared to assimilate starchy food perfectly, and in whom sugar had twice disappeared, and yet who subsequently developed a severe diabetes.

2. **Griserin.**—Petruschky has made many experiments with loretin and its salt griserin, and concludes that not only is the drug incapable of preventing the development of anthrax, for instance, but that it has some toxic qualities for the animals used in the experiments.

3. **Lead Poisoning of the Eye.**—Lewin enumerates the substances employed in industries which affect the eyes injuriously, such as lead, bromide of ethyl, mercury, arsenic, and its salts, the anilines, etc. The lead poisonings are the most important, as they are the most frequent. They may be either acute or chronic. The lesions are retinal inflammation and optic atrophy, corneal turbidity, spasms, and paralyses of the ocular muscles. The saddest cases are those in which blindness appears over night and those of optic atrophy. The "lead line" in the gums is not a reliable symptom.

4. **Solutions in the Stomach.**—Sommerfeld and Roeder conclude that every solution introduced into the stomach without the previous action of the saliva changes its molecular concentration in such a way that solutions isotonic and hypertonic as to the blood, become diluted, solutions hypotonic becoming heavier. Hypertonic solutions have a higher freezing point than the blood even after five hours' sojourn in the stomach, thus leaving the stomach in a hypertonic state. No increase in the quantity of fluid in the stomach could be demonstrated.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

January 14, 1905.

1. The Ocular Symptoms of Lesions of the Optic Chiasm, with the Report of Three Cases of Bitemporal Hemianopsia, By G. E. DE SCHWEINITZ and JOHN T. CARPENTER.
2. The Mathematical Point of Reversal in Skiascopy, By SWAN M. BURNETT.
3. Syphiloma of the Ciliary Body, By HERMAN KNAFF.
4. Temporal Cleft of the Nerve Head, By CHARLES H. BEARD.

7. Is Pneumonia Increasing? By JOHN S. FULTON.
8. The Management of Hernia in Infancy and Childhood, with Results of Operative Treatment, By WILLIAM B. COLEY.
9. The Schott Method of Treating Diseases of the Heart and Blood Vessels, By JAMES M. ANDERS.
10. Paraurethritis. An Anatomical Review, with Report of Two Cases, By J. W. CHURCHMAN.

7. **Is Pneumonia Increasing?**—Fulton in a rather elaborated statistical paper shows that in all probability pneumonia is not increasing in the United States. Several causes have led to an apparent increase of the disease. (1) Formerly there were many cases of death held to be due to unknown causes. At present diagnosis being better understood the known diseases are to a large extent credited with such deaths. (2) Formerly many children were reported as having died of convulsions, worms, teething, etc. At present such absurdities are not so frequent. Again the known causes of death absorb these cases. (3) Formerly many cases of pneumonia were thought to be cases of nervous or brain disease. (4) Mortality statistics are very badly kept.

8. **Hernia.**—Coley asserts that, roughly speaking, herniæ in infants and children under the age of 4 years can be cured by carefully directed truss treatment in about two thirds of the cases, although it is probable that, in after years, a considerable percentage will relapse. Beyond the age of 4 years, in a fair proportion of the cases, a cure can be effected by means of a truss, provided the truss is properly fitted in the first place, and the child is regularly seen by a surgeon for a period of not less than two years. In very young children it is best therefore not to operate at once. However, even in children under four years of age it is best to operate in the following cases: (1) If there is a history of strangulation that has become reduced by taxis, an operation is indicated, no matter how young the child. (2) In cases in which, despite carefully directed truss treatment, the hernia has become irreducible, or reducible with difficulty. (3) In cases in which the rupture cannot be controlled by a truss and, as a consequence, is gradually increasing in size. (4) In all cases of femoral hernia, the reason for prompt operation in this class being that a cure by persistent truss treatment is practically unknown at any age. (5) Immediate operation is indicated in all cases of hernia associated

with reducible hydrocele or fluid in the hernial sac, inasmuch as it is impossible to control the rupture by means of a truss, and there is, hence, nothing to be gained by waiting. The Bassini operation is probably the best for inguinal hernia. The author uses chromicized kangaroo tendon in place of the buried silk sutures and puts an additional stitch above the cord. For femoral hernia the author's method is, first, to thoroughly free the sac well beyond the neck; high ligation of the sac and closure of the canal by means of a purse string suture of chromicized kangaroo tendon. The suture is introduced through Poupart's ligament or the inner portion of the roof of the canal, or crural arch, from where it passes downward into the pectineal muscle or floor of the canal, outward through the fascia lata overlying the femoral vein, and upward through Poupart's ligament or roof of the canal, emerging about three fourths of an inch from the point of introduction. On tying the suture, the floor of the canal is brought into apposition with the roof, and the femoral opening is completely obliterated. The superficial fascia may then be closed with catgut or fine tendon, and the skin either with catgut or silk.

BOSTON MEDICAL AND SURGICAL JOURNAL.

January 12, 1905.

1. The Systematic Use of Work as a Remedy in Neurasthenia and Allied Conditions, By HERBERT J. HALL.
2. Improved Technics for End to End Intestinal Anastomosis, By ALFRED H. GOULD.
3. Observations on Experimental Drainage of the Peritoneal Cavity of Cats, By FRED T. MURPHY.
4. A Consideration of Autointoxication and Autoinfection as Cause of Various Mental Disorders, By L. VERNON BRIGGS.

1. **Neurasthenia.**—Hall does not believe that neurasthenia is generally due to overwork. The condition is essentially a psychic one dependent for the most part on worry and bad habits generally. A physical rest cure is not therefore the ideal mode of treatment. What is needed is systematic occupation for the patient's mind and body. Hall has obtained good results in a limited number of cases with the following plan of treatment: For a week or so rest in bed. Then without warning or discussions the patient is required to do something. At first the act may be a trivial one, such as sitting up in bed for a short time. A particular act is never repeated on a succeeding day. As soon as the patient is sufficiently improved manual occupations are assigned, such as basket making, weaving, pottery making, etc. Such tasks are to be undertaken seriously and what is produced is sold in the open market. A more or less complete workshop is of course required. The results that have been obtained by this plan of treatment are encouraging.

2. **End to End Anastomosis.**—Gould in his third paper on proposed improvements in surgical technics considers end to end anastomosis. He proposes a new method of doing an all suture operation. Two layers of stitches are employed. An internal through and through stitch and an external seromuscular one. The only original

feature of this technics is the manner of beginning the first layer of continuous stitches. These are begun at the mesenteric attachment. The article is illustrated.

3. **Drainage of the Peritonæum.**—Murphy tabulates and discusses his experiments. The following methods of draining were employed: Gauze, cigarette drains, rubber and glass tubes. Roughly summarized, the gauze and cigarette drains failed to drain the general cavity after about eighteen hours, and the rubber dam and glass tubes after about the third twenty-four hours, the difference in the time representing the difference in the stimulating effect of the various materials on the peritonæum. In all instances, the omentum was the active agent in the process of walling off, the actual adhesions between the loops of intestine being difficult to demonstrate. While the omentum in the cat is extremely large, it is not improbable, judging from findings at operation and autopsy, that the human omentum when large plays an equally active part. Provisionally and within certain limitations the following advice may be given: (1) If the object of drainage in any given case is to have a certain septic area walled off as soon as possible then a gauze or a cigarette drain should be used. (2) If drainage of the general peritoneal cavity is desired glass or rubber tubes should be employed. They will probably not drain after seventy-two hours.

AMERICAN MEDICINE.

January 14, 1905.

1. The Foundation and Aims of Modern Pædiatrics, By Dr. THEODORE VON ESCHERICH.
2. Comparison of Röntgen Ray and Surgical Treatment of Tuberculosis, By JAMES B. BULLITT.
3. The Early Recognition of Hypertension, By HENRY WIREMAN COOK.
4. Intussusception of the Appendix Vermiformis, By GEORGE EMERSON BREWER.
5. Lithæmia: Its Diagnosis and Local Treatment, By F. M. JOHNSON.
6. Three Interesting Cases: Gastroptosis and Dilatation; Chronic Tenosynovitis; Thoracic Abdominal Aneurysm, By G. CHILDS MACDONALD.
7. The Society for Experimental Biology and Medicine, By WILLIAM J. GIES.

2. **Tuberculosis.**—Bullitt has collected 616 cases of skin tuberculosis and 518 cases of other forms of local tuberculosis that have been treated by the x ray. Of the cases of skin tuberculosis 420 or sixty-eight per cent. were reported as cured. The 518 cases are divided into six groups, according to the location of the lesions. The number of cures claimed range from thirty-three per cent. in the case of tuberculous testicles to seventy per cent. in the case of disease of the tendon sheaths. The author holds that the efficiency of the Röntgen treatment of lupus is established but that the efficacy of this form of treatment for other forms of local tuberculosis is still subjudice.

3. **Hypertension.**—Cook concludes: (1) A large and increasing proportion of deaths is due to cardiovascular disease. (2) Cardiovascular af-

fections in a majority of cases are accompanied and in many cases antedated by a rise in arterial tension, which bears an important causal relation to the terminal organic lesions. (3) An early recognition and continued observation of this rise in tension is a most valuable element in the recognition, prophylaxis and corrective treatment of such conditions.

4. **Intussusception of the Appendix.**—Brewer's case was briefly as follows: A girl of twenty-two years exhibited signs of appendicitis. Operation revealed dense adhesions about the cæcum. No appendix was found. Recovery from operation ensued and in due time there was a recurrence of former symptoms. A second operation revealed a stricture of the colon just above the ileocæcal valve. The colon was incised for relief of this stricture. This incision brought to view the invaginated appendix. Appendectomy and suture of the wound in the colon were done in such a manner that the original longitudinal wound was turned into a transverse one, thus obliterating the stricture. Recovery followed without recurrence of the previous symptoms. Query, How did the appendix become invaginated?

5. **Lithæmia.**—Johnson devotes special attention to the diagnosis of lithæmia by the aid of the microscopical study of the urinary sediment. Five cuts serve to make clear the author's statements. With regard to treatment, emphasis is laid on the value of bladder irrigations and lavage of the kidneys by means of ureteral catheters.

MEDICAL NEWS.

January 14, 1905.

1. Care of Puerperæ, By JAMES D. VOORHEES.
2. Trauma and Chronic Compression of the Epigastrium as Ætiological Factors of Gastric Ulcers, By WILLIAM ACKERMANN.
3. The Nervous Symptoms Accompanying Pernicious Anæmia, By ROY M. VAN WART.
4. Prostatectomy in Emergency Cases, By JOHN F. ERDMANN.
5. Observations on the Blood Pressure in Disease, By ROGER S. MORRIS and CHARLES W. EDMUNDS.

2. **Gastric Ulcer.**—Ackermann believes that trauma of the upper abdominal and epigastric region whether it be acute, as by a blow, or chronic, as by more or less constant pressure from corsets, posture (as in sewing, bent over), or by tools, is one of the most potent ætiological factors of gastric ulcer. The histories of sixteen cases are reported in order to sustain the author's contention. Experimentally, upon animals, it can be shown that in a certain number of cases trauma is capable of giving rise to condition of the gastric mucosa that will eventually lead to the formation of ulcer.

3. **Pernicious Anæmia.**—Van Wart reports a case of pernicious anæmia which was complicated by marked spinal symptoms. Nervous symptoms associated with this condition have been frequently noted. It was not, however, till 1887 that gross anatomical lesions of the cord were reported as existing in conjunction with this disease. These lesions of the cord may or may not produce symptoms. The ætiology of these lesions, as well as the

ætiology of pernicious anæmia, still remains in doubt. It is not improbable that they are both due to the same cause, whatever that may be.

4. **Prostatectomy.**—Erdmann calls attention to the advantage of doing a prostatectomy in every instance possible when the prostate is in part the cause of obstruction in cases coming under the head of emergency drainage of the bladder. Eight such cases are reported in which a prostatectomy was done. They are of six types. (1) Impassable urethra due to stricture with rupture and gangrene of the entire scrotum and perinæum. (2) Retrograde hæmorrhage, bladder being full of clots and bloody urine, with malignancy of the prostate. (3) False passage; retrograde hæmorrhage; suprapubic aspiration with infiltration of the abdominal wall extending to the thorax and to the gluteal regions. (4) Acute obstruction due to exposure to cold and wet, inability to catheterize; trauma of the urethra. (5) Trauma of the urethra; catheterization for several days, retrograde hæmorrhage, etc. (6) Deep stricture of the urethra; obstruction; catheterization cystitis with absorption. In similar cases emergency operative procedure is recommended because: (a) Only a few minutes more are required to remove the gland, the hæmorrhage as a rule is not excessive, and the operative procedure itself does not increase the shock to any degree. (b) The removal of the prostate gives proper exit to the urinary outflow and admits of easy drainage. (c) Washing the bladder is much facilitated. The perineal route is recommended in emergency operations because: (a) The opening is practically at the lowest point of the bladder and complicated devices for drainage such as are necessary in suprapubic sections are not required; (b) The old, being irritable and feeble and requiring to be moved frequently, the drainage in the suprapubic method is constantly interfered with, while in the perineal method it is readily controlled. (c) The after soiling, when the tube is removed, is slight and easily controlled in the perineal method as compared with the suprapubic. (d) Bladder irrigations are more readily done with less soiling to the bed, etc., by this method.

MEDICAL RECORD.

January 7, 1905.

1. On the Healing of Tuberculosis (Clinical Features), By HERBERT MAXON KING.
2. The Art of Eating Properly (Euphagia) and the Harm of Eating Too Rapidly and Too Slowly (Tachypagia and Bradyphagia), By MAX EINHORN.
3. A Recent Epidemic of Typhoid Fever, By JOHN BRADFORD BRIGGS.
4. Three Cases of Excessive Fœtal Development, By JULIUS ROSENBERG.
5. Spleenless Men, By J. H. CARSTENS.
6. An Experimental Study of the Movements Produced in the Stomach and Bowels by Electricity, By G. G. MARSHALL.
7. Definition and Classification of Gastric Hemorrhage, By F. GREGORY CONNELL.
8. A Case of Sciatic Neuritis with Paralysis Following Malaria, By WILLIAM GEORGE RUSSELL.

1. **Tuberculosis.**—King leans to the belief that practically every one who has reached maturity

has at one time or another harbored the tubercle bacillus. The first infection tends to spontaneous cure, which, however, is not apt to persist. It is probably the recrudescence of an old infection which is generally taken to be the actual onset of the disease. Some case histories are given in order to illustrate this point. The author believes that the truth of the following propositions should be further investigated: (1) It is probable that the initial lesion following a tuberculous infection is often obscure in its clinical manifestations and frequently escapes identification. (2) There is nearly always a prompt and very often successful tendency on the part of the organism to a more or less complete repair followed by an interval of apparent health. (3) Following this interval, which may extend into a period of years, there is a strong tendency to relapse. (4) What is in reality a recrudescence of an arrested lesion is very frequently mistaken for an initial onset. (5) Whatever may be the facts in an individual case, the safest and most practical policy lies in regarding every apparent recovery from tuberculosis as merely an arrest of the disease, brought about by an acquired immunity which suitable conditions are very prone to destroy.

3. Typhoid Fever.—Briggs reports his study of a small epidemic of typhoid fever which took place in western Pennsylvania. It shows, what has been so often shown before, that typhoid is essentially a water borne disease and that if sewage containing typhoid excreta is allowed to get into the drinking water the disease is bound to spread. He insists that it is the duty of every physician attending typhoid patients to make sure that the patients' excreta and bath water are properly disinfected. The stools should be immersed for two or three hours in twice their bulk of five per cent. carbolic acid solution. Urine should be treated with carbolic solution. It is best to boil the linen. The bath water may be rendered harmless by adding to it one quarter pound of fresh chloride of lime and then allowing it to stand for one hour.

4. Excessive Foetal Development.—Rosenberg reports his three cases in detail. All the women had practically normal pelvises. In the first case craniotomy was performed. In the second case version was successful and a living child (weight 13 pounds) was delivered. In the third case version was attempted and delivery finally accomplished by perforating the after-coming head. The author admits that all these cases were suitable ones for Cæsarean section. The difficulty is to make a correct diagnosis and then have suitable conditions.

5. Spleenless Men.—Carstens holds that the chief indications for splenectomy are: (1) So called splenic anæmia; (2) traumatism; (3) malignant disease. The spleen has been often removed for other conditions, at times probably not advisedly. Two cases of splenectomy are reported: one for sarcoma and one for so called splenic anæmia. Both patients recovered. The author concludes: (1) In diseases of the spleen, blood examination must be made. (2) Splenectomy will cure a certain number

of cases. (3) Spleenless men can live in perfect health, as we are unable to find any difference between the blood of such men and the blood of those who have not been subjected to splenectomy.

6. Movements of the Stomach and Bowels.—Marshall has attempted to determine what movements, if any, may be produced in the stomach and bowels by direct applications of the electric current. He concludes: (1) The stomach and bowels do not readily contract under the direct application of electricity. (2) Electricity as generally administered never causes contractions or peristaltic movements of the stomach and bowels.

of Lobar Pneumonia Treated at the American Hospital,
Mexico City, from 1890 to 1904.
By ALBERT R. GOODMAN.

1. Diseases of the Canal Zone.—Sutton discusses briefly the chief diseases which are most frequently met with along the Panama Canal zone. They are: Malaria, all forms except the quartan variety, which is rare; dengue, which specially attacks the white man; beriberi, chiefly seen among the Chinese; diseases due to intestinal parasites. All the natives suffer from such infections, eggs from as many as six varieties of parasites are frequently found in a single stool. The Uncinaria duodenalis produces the most serious symptoms. Heat exhaustion, sunstroke, and yellow fever are more or less frequent. Among the insects the jigger (*Pulex penetrans*) is probably the most annoying. Dysentery was the scourge of the old French company. It is of two kinds; the amebic and that due to the Shiga bacillus.

3. Sudden Death.—Robinson reports eighteen cases of sudden death. Most of them were probably due to emboli and they nearly all followed surgical operations. Most cases of sudden death are probably due to defects in the circulatory system. The nervous system has been much overrated as a factor in the production of sudden death.

5. Cholecystitis.—Harvey admits that some cases of cholecystitis get well without the aid of surgical intervention yet he holds that it is the part of wisdom to advise operation early. Either cholecystostomy or cholecystectomy will put an end to the trouble. The author appears to consider the gall bladder a superfluous organ and so inclines to its extirpation as the operation of choice.

6. Pneumonia.—Goodman's paper is entirely statistical. The mortality percentage of the cases reported was forty-three and five tenths per cent. However the records seem to have been rather im-

perfectly kept and a number of different physicians were responsible for the treatment given.

3. A Case of Streptococcic Puerperal Infection Treated with a Special Puerperal Antistreptococcic Serum: Recovery, By T. ROSE.
4. On the Administration of Antistreptococcic Serum, By J. W. T. WALKER.

1. Treatment of Phthisis.—Mackenzie considers the recognized methods of treatment of phthisis. In the first rank as remedies must be placed pure air and sunshine, good food, suitable clothing, proper housing, with regulated rest and exercise under medical supervision. The recognition of the value of fresh air is the most marked advance in the treatment of pulmonary tuberculosis. The advantages of the fresh air treatment are as follows: Gain in appetite; better assimilation of food; and sounder sleep. Fresh air is the best antipyretic; night sweats usually cease and colds are practically unknown among these patients. Secondary infection, owing to the paucity of microorganisms in the air, is less likely to occur. Sunlight and fresh air improve the quality and increase the oxygenating power of the blood, stimulate metabolism, and quicken the activity of the nervous system. Feeding is of paramount importance, yet save in exceptional cases anything like stuffing is quite unnecessary. Three good meals a day should be given and nothing during the intervals. The capacity of tuberculous patients to put on flesh is remarkable, and care must be taken that this does not occur too rapidly or to excess. Alcohol, wisely used, is of value, but it is powerless to prevent the incidence and progress of pulmonary tuberculosis. It is most valuable in acute cases and late in the disease. Too much wrapping up is as much to be avoided as too little. When patients are up and about overcoats and wraps should be used only when they are resting. The patient's room should be large and have a southern exposure. The chief guide in the matter of rest is the temperature. Continued fever calls for absolute and complete rest, and this holds also where the evening temperature is over 101° F. The morning temperature should determine whether the patient is to get up. The rectal temperature is the most trustworthy index. Patients up all day should rest for half an hour in the recumbent position before lunch and dinner. Walking is the best form of exercise: the length, direction, and rate must be adjusted to the individual case. The longer walk of the day should be taken shortly after breakfast. Any excessive exercise will cause a rise of more than two degrees in the temperature. All violent exercise (cycling, skating, swimming, riding, dancing, etc.) must be emphatically vetoed in cases where the disease is active. Home treatment, where the desired conditions can be obtained, compares favorably to that in sanatoria. But at a sanatorium there is constant supervision, removal of all disturbing influences, and the

patient is taught how to live. The question of climate is difficult, and the suitability of the location to out door life plays a large part. Sea voyages should never be advised where there is active disease. Fever and hæmoptysis call for absolute rest. In laryngeal cases the voice must be used as little as possible. Drugs are being used less and less: they are most useful in relieving symptoms.

2, 3, 4. Antistreptococcic Serum in Puerperal Fever.—Foulerton reviews the history of the use of antistreptococcic serum in puerperal fever, since its introduction by Marmorek. In clinical practice its action contrasts strongly with that of antidiphtheritic serum. In the latter the administration of a sufficient dose is usually followed by immediate improvement, and the dose does not have to be repeated. In puerperal fever, on the other hand, when improvement has followed the first injection of serum, it has been necessary to repeat the dose after a time. A patient almost moribund with streptococcic infection will be greatly benefited by the serum: yet the symptoms may, and often do, recur within twenty-four hours. It would seem that the action of an antistreptococcic serum is purely antitoxic, and the streptococci themselves are not affected by its use. The infecting bacteria, unaffected by the serum given, continue to elaborate their specific toxins. So that in order to neutralize the toxins, repeated doses of the serum must be given until the infection comes to a natural termination. Treatment should be begun with an injection of at least twenty cubic centimetres, and if necessary this dose must be repeated every twenty-four hours. It is useless to persist in the use of a particular antistreptococcic serum unless its beneficial action is at once apparent. Any toxic symptoms, such as cutaneous eruptions and transient arthropathies, are due to the serum itself and not to the antitoxine contained therein. Rose reports a case of pure streptococcic infection occurring in a woman aged twenty-nine years. The symptoms were most severe, the patient passing into coma after two days' delirium. Foulerton's serum was used, with immediate beneficial effect. Three doses of five c.c. each were given during the first twenty-four hours, and a fourth dose of twenty c.c. twenty-four hours later. Walker draws the following conclusions: 1. That injection of antistreptococcic serum in cases of pure streptococcal infection has been followed by strikingly beneficial results. 2. That variability in the results of the serum in proved streptococcal infection has been due to the selective activity displayed by the antitoxine of each variety of streptococcus or to the serum being used too late in the case or having lost its activity from staleness. 3. That more uniform results are likely to be obtained from the present "compound" antistreptococcic serum than from the earlier forms, from the prompt injection of serum at the commencement instead of near the close of a severe infection and from the use only of serum which has been recently prepared. 4. That the initial dose may with benefit be increased and that a large quantity spread over several days, causes no ill effect. 5. That the administration of the serum should be continued for some days after the general symptoms have disappeared and a recrudescence thus avoided.

6. The Anthropometric Investigation of Hospital Patients, By F. C. SHRUBSALL.
7. (Report No. XC to the Scientific Grants Committee of the British Medical Association). The Lymph Flow from the Pancreas, By F. A. BAINBRIDGE.

1. **Uterine and Ovarian Tumors.**—Swain's paper is based on the tabulation of fifty operations. Among his conclusions are the following: Hysterectomy for cancer is very unsatisfactory in its remote results. Uterine hæmorrhage after menstruation always calls for an examination for it is only in the early cases of cancer that the outlook is good. In early cases colpohysterectomy is the best operation: the primary mortality and the incidence of recurrence are distinctly lower. The presence of a myofibroma is in many cases a menace to the life of a patient: one of the commonest causes of death is from the pressure effects of a large myofibroma. Hæmorrhage or necrotic changes in the tumor may also cause death. The hard myofibroma grows slowly and usually atrophies after the menopause. The soft myofibroma, usually single, grows much more rapidly, is independent of uterine conditions, and is unaffected by the menopause. The chief indications for treatment are the size of the tumor, profuse hæmorrhage, diseased conditions of the ovaries and tubes, or rapid increase in the size of the tumor. Myomectomy is the operation of choice in young women, providing the general condition is good, that the tumor does not extend above the umbilicus, and that there are no important complications. Where it is undesirable reoperitonal hysteromyomectomy is preferable to panhysteromyomectomy.

3. **Pancreatic Disease.**—Moynihan discusses the signs and symptoms of pancreatic disease in the following order: *Glycosuria*. The internal secretion of the pancreas, which regulates carbohydrate metabolism, is derived from the islands of Langerhans, and from them alone. Any lesion destroying the islands (a hyaline degeneration is the most common) results in diabetes. But many other lesions—*e. g.*, of the nervous system—may result in glycosuria. In "bronzed diabetes" a chronic interstitial pancreatitis is present. Hæmochromatosis, or deposition of pigment in the organs of the body, has as its natural termination diabetes of the bronzed type. *Steatorrhœa*. The presence of fat in

the stools is by no means pathognomonic of disease of the pancreas. Fat is normally present in the stools, about five per cent. of the fat taken being discharged as unaltered. If an excess of fat is taken in health, a proportionate excess is found in the fæces. In simple catarrhal jaundice the amount of fat in the fæces is almost doubled. *Steatorrhœa* when associated with azotorrhœa in the absence of jaundice, points strongly to pancreatic disease. With azotorrhœa, diabetes, and epigastric tumor, it is evidence of undoubted pancreatic disease. *Azotorrhœa*. The presence of undigested nitrogenous food in the stools (such as muscle fibres) is sometimes seen in pancreatic disease, but it is an extremely inconspicuous symptom. *Fat necrosis*. This is most commonly found in association with acute pancreatitis, of the hæmorrhagic or gangrenous forms, but may also be found in chronic interstitial (interlobular) pancreatitis. It is wholly dependent upon lesions of the pancreas, and its significance is therefore considerable. *Jaundice*. In chronic pancreatitis or in malignant disease of the head of the pancreas, the enlargement of the gland presses upon the common bile duct and jaundice results. Courvoisier's law is that persistent jaundice with a distended gall bladder depends upon cancer of the head of the pancreas.

4. **Enlarged Prostate.**—Dudgeon and Wallace have studied the bacteriology of enlargement of the prostate. In most of their observations the tumors removed from the prostates showed unmistakable signs of infection by microorganisms, and in some instances the infecting organisms were the same as those found in the urine. So that the initial lesion in prostatic enlargement may in certain cases be a septic infection from the bladder.

6. **Hospital Anthropometry.**—Shrubsall's conclusions, drawn from his anthropometrical investigation of hospital patients, are as follows: 1. That certain diseases show special affinities for certain types of the population. 2. That adult hospital patients, as a whole, are slightly fairer than the population within the sphere of attraction of each hospital. 3. That with each successive generation of city life the fair element sends an undue proportion of its members to the hospitals. 4. That child patients are markedly fairer than the children in the districts around the hospitals. 5. That diminution in stature and increase of brunette traits are almost certainly progressive with increased heredity of an urban environment.

7. **Lymph Flow from the Pancreas.**—Bainbridge's conclusions are as follows: 1. The injection of secretion or ileum extract causes an increased flow of lymph from the thoracic duct. 2. After ligation of the portal lymphatics secretion still causes an increased flow of lymph, whereas ileum extract has no effect. 3. The increased lymph flow produced by secretion is not caused by the depressor substance, but by secretion itself. 4. There is a close relation between the secretion of pancreatic juice and the increased flow of lymph. The lymph is derived entirely from the pancreas, and is probably formed as a result of metabolic changes occurring in the pancreas during the secretion of juice.

Letters to the Editor.

OPTOMETRY.

17 WEST TWENTY-EIGHTH STREET,

NEW YORK, December 23, 1904.

To the Editor,

SIR: There appeared in your *Journal* a few weeks ago an open letter from Dr. Van Fleet, addressed to the medical profession, which should not be allowed to pass without some notice. He asserts that "many of the names" of the physicians indorsing the bill "were fictitious," a rather serious charge to bring against the committee of the State Optical Society. Again, he says that "every well informed physician must know that they (optometrists) are all incompetents." What about the hundreds of physicians of high standing throughout the State who send their patients to optometrists for the reason that they believe that the work will be better done, and because no drugs are used in making the examination. This is a matter of record and cannot be denied or gainsaid. He says, further, that we "seek to treat headaches, dizziness, and the various reflex phenomena which may be due to affections of the eye itself or to affections of organs remote from the eye." How absurd and ridiculous! Our work is simply this, to measure accurately all mechanical defects in the construction of the eye or its controlling muscles and to supply lenses to correct these defects. Should headaches and various other troubles be relieved as a result of our work, so much the better for ourselves and the patient.

Another astounding statement he makes to the effect that "to prepare physicians to do this work (optometry) the law requires that a four years' course in a medical college shall be taken, after which a medical examination conducted by the State must be passed." It is difficult to see how any truthful, fair minded man could bring himself to make such a statement, for it is absolutely untrue. Nowhere does the law require any course, long or short, in medical colleges or elsewhere, or any examination whatsoever by the State, to prepare physicians or any one else to do this work (optometry). The field is now open to all comers, from the "well informed" physicians like Dr. Van Fleet down to the common peddler and street fakir who stands on the corner and sells his glasses to the unsuspecting and unwary.

Our object in seeking legislation on this subject is to prevent incompetents (whether they are found in the ranks of the "well informed physicians" or elsewhere) from engaging in this work. All should be obliged to undergo a strict and searching examination before a State board, and those who refuse to do so and who continue to oppose the enactment of this wise and beneficent measure should be branded as incompetents. Is it not rather strange that the men who profess to be alone qualified to practice optometry by reason of a four years' course in a medical college have only allotted to them in the study of the eye in all its branches the maximum time of thirty-two hours during the whole four years' course, while those who have given years of study exclusively to optometry are declared by these

aspirants to be "all incompetent"? But his closing statement is certainly the most ludicrous. We are told that "opticians know that they are violating the law in following the occupation which they are now engaged in," and that "the enactment of the bill will give them the legal right to do what they are now doing in violation of the law." I would ask, if we are violating the law, why is it that the chairman of the committee on legislation of the medical society is neglecting his duty and does not prosecute us?

Our cause is surely a just one, our purpose honorable, and our profession a noble one. Sooner or later we shall receive recognition and suitable legislation, just as the dentists fought and won their battles against the self same forces and many of the same arguments as are being used to-day. Who can deny that dentistry is infinitely better done to-day than before the dentistry laws were enacted? So it will be with optometry. The public will then know who are competent to do this work, and fakirs, peddlers, and incompetents will be relegated to the past.

A. MARTIN.

Proceedings of Societies.

NEW YORK PSYCHIATRICAL SOCIETY.

Meeting of November 2, 1904.

DR. ALLAN McLANE HAMILTON in the chair.

Some Evidence That Early Paresis May Be Arrested and Practically Cured.—Dr. CHARLES L. DANA considered paresis a parasyphilitic disease, i. e., one due to the degeneration induced by syphilis, and not to the exudations of syphilis. This degeneration might occur without any previous evidence of any exudative trouble. Formerly he believed in a syphilitic pseudoparesis, but further observation showed that such cases were due to an exudative syphilis, with the addition of degenerative changes, a coincident development of exudation and degeneration. These patients might improve and remain improved for a long time, but no matter how thoroughly the treatment cleared up the exudation, there was left some degeneration and some clinical stigma of real trouble. Other cases would not improve, but pass into real paresis. These cases were not really cured and were perfectly analogous to the so called syphilitic pseudotabes, in which we nearly cured the case, but not quite, and, in after years, the degeneration might set in again and true tabes develop.

There being, then, but one paresis, and this due to the degenerative influence of syphilis, it followed that the criteria of diagnosis were those symptoms which indicated that the patient had had nervous syphilis, and had now evidences of some nerve degeneration and coincident mental change.

With the increasing attention paid to paresis of late years, one was more often able to note its earlier symptoms, and these were almost always somatic. Perhaps the very first group of symptoms was a change of character, a lessening of interest in work, greater irritability, and inattention. Sometimes this was so slight that it escaped notice unless attention was called to it. The very earliest symptom might be a cranial nerve palsy (as in tabes) which in time

called attention to unequal pupils, persistent dysæsthesias of the head and neck; a fainting turn, or convulsion, or a sunstroke might also be among the earliest symptoms, as well as a very persistent headache with a mild type of melancholia. These patients might also present exaggerated reflexes, exaggerated facial responses, especially the nasal reflex. There might also be an apparent acceleration of and intensity in reflex response, as shown by the quick reaction to questions and overaction of the muscles in responses. All these things might be seen without any of the definite stigmata of paresis, such as decided dementia, exaltation and delusions, marked speech disturbances and tremors.

Here Dr. Dana detailed the histories of several cases by which he attempted to prove his contention. He said the contention might be that the cases reported were only cases of cerebral syphilis with arterial thickening and consequent cerebral and mental changes, but this was not the way it appeared to him. In his cases there had always been some coexisting psychic changes. In cerebral syphilis the patients had many discomforting sensations and might perhaps be hypochondriacal, not quite up to their old selves, and there the matter ceased. They might have no signs of a dementing or other psychosis. When a patient had cerebral syphilis with exudation, he had terrible headaches, eye palsies, hemiplegia, bulbar troubles, etc., and when these cleared up there always existed the possibility of paresis setting in. Sometimes it did, if one did not recognize and appreciate the very earliest period when the danger threatened. Then paresis might be averted.

Dr. Dana felt justified in saying that if they were able to get hold of a certain number of cases before the speech disturbances or decided dementia occurred, they might arrest the trouble and hold it in check as they did in early tabes. He contended that they could do in early paresis what they could do in early tabes.

The CHAIRMAN asked Dr. Dana what treatment he employed—if anything more than the antisyphilitic treatment.

Dr. DANA replied that he insisted upon the absolute removal of the patient from his previous surroundings, with the liberal use of water internally as well as externally. The iodides and mercury were given in liberal doses. In some cases the salts of mercury might be given hypodermically, either the bichloride or the salicylate.

Dr. Dana referred to another case with hypochondriacal symptoms, the Argyll-Robertson pupils, etc. This patient had been treated by Dr. Keyes with hypodermics, which simply seemed to keep him in fairly good condition, but did not cure him. Under further treatment he did get well. Dr. Dana was sure that if further treatment had not been tried the patient would have died of paresis years before.

Dr. A. E. MACDONALD did not think that the diagnosis of the cases reported by Dr. Dana, except the first one, was conclusive. A question he had in mind to ask had been anticipated by Dr. Dana, i.e., whether there was in this case anything more than the remissions to be looked for in all those cases that received prompt hospital treatment. In such cases he looked for just such a suspension of the

symptoms as described by Dr. Dana. He had found it often a very difficult thing to satisfy the friends of such patients that treatment should be continued, because the improvement was so marked that they objected to the patient remaining longer in the hospital and alleged that he had recovered.

Dr. ADOLF MEYER said that the question was an exceedingly difficult one on which to come to any definite agreement, essentially on account of the fact that it was difficult to say when general paralysis could be considered as established. The first case that Dr. Dana had cited was such as could have given rise to little doubt, with its marked expansiveness, yet Dr. Dana took pains to describe it as one of but slight exaggeration of attitude of the normal Wall Street man. A great deal of weight would have to be placed upon the forgetfulness and on inconsistencies. In one of the cases very little forgetfulness and no real dementia was said to have been present in the account of the case; but from a retrospective point of view, in the statement that the patient had recovered, he was said to have recovered from his dementia. The fact of there having been distractibility of attention before was then interpreted as a beginning dementia. To be sure, it was exceedingly difficult to demonstrate with any certainty whether one was dealing with an actual deterioration or memory defect, for several reasons. He would be especially cautious in the use of the term dementia where the only evidence was a certain feeling of insufficiency in the patient, an exhaustibility, and in the interpretation one might easily be biased by the suggestion that the patient had had syphilis before. *A priori*, one would naturally think that, since general paralysis was a disease with a definite, generally slow evolution, we should come across *formes frustes*, which were merely approaching the period of decided development. If one could determine what made it sure that the patient had the disease, matters would be much simplified; but this was a very difficult thing to do at the present time. To him it would seem certain that he would demand a consistency of the physical and the mental process. The cytodagnosis should be positive, a point of value, although the ordinary forms of syphilitic affections had also positive reactions, and not only general paresis. The question of what constituted paralysis had lately been brought under consideration by Nissl, who had split off a diffuse cerebral syphilis, and especially by Gaupp, who had lately reviewed carefully the cases of so called recovery from general paralysis. His review of the situation had been destructive to evidences of recovery, and Dr. Meyer said that he certainly would be exceedingly hesitant in accepting the proposition as proved.

Dr. L. PIERCE CLARK said that the histories of the cases Dr. Dana had presented were very suggestive of paresis, and in most of the cases he thought all would reach the same tentative diagnosis. The final termination, however, would show the error in diagnosis. We must, in the first place, demand the established clinical entity of paresis—the well known psychic symptomatology of paresis, particularly mental deterioration. It was conceivable that general paresis must present a period when deterioration would be but slightly in evidence; pos-

sibly a diagnosis at such a time would more nearly approximate the contention of Dr. Dana.

His personal opinion in the matter of the curability of paresis centred on the question of early diagnosis. It had not been proved that such a diagnosis was yet possible. In his asylum experience patients had often been admitted so early in general paresis that another diagnosis had been entertained for a long time, yet recovery never occurred. In such cases remission and non-progression of the disease were often present for several years, yet the patients were ultimately destroyed by paresis. If iodides and mercury were at all effective in suspected cases, then paresis was legitimately in doubt. He had never known paresis in any degree to be favorably influenced by these drugs. Improvement and remission, on the other hand, were brought about by general care, hydrotherapeutics, diet, rest, and quiet, simple living. Paresis, from a chemicopathological as well as a clinical view point, was a parasymphilitic affection, a postsymphilitic toxic disease. It was beyond the reach of antisymphilitic remedies as such. It was important to remember also that in many undoubted cases of paresis these drugs did harm. He looked upon Dr. Dana's first case as one of probable paresis with a remission. He thought the others were anomalous types of cerebral lues. There was no doubt that the asylum cases were of the worst type, incurable. Since being in private practice he had seen cases in which by the aid of such natural healing methods as had just been mentioned long remissions and delays in the progress of the disease had been brought about that were not possible in private asylums. He thought that the curability of early general paresis was mentally conceivable, but we were very far from realizing its practical accomplishment at present; therefore it must be classed as one of the most hopelessly incurable mental diseases.

Dr. FLAVIUS PACKER said that those who were engaged in asylum practice must look upon paresis as practically incurable. We had cases which presented long periods of remission, yet the patients returned, and when he was satisfied with the diagnosis the incurability of the disease had never been questioned. One patient left the hospital during a remission and was away a year and a half, when he returned. He believed the question of an exact diagnosis in these cases to be very important.

Dr. CARLOS F. MACDONALD thought that the correctness of Dr. Dana's attitude respecting the curability of paresis or, more properly, general paralysis of the insane, was based upon an experience and observation of cases for more than thirty years, both in hospitals for the insane and in private practice; his view was that this was a form of insanity having a distinct entity and essentially different from any other form of insanity, just as scarlet fever differed from smallpox, having its own pathology and clinical history, with a characteristic combination of diagnostic symptoms which alone would warrant a diagnosis. He knew that many writers spoke of making a diagnosis of paresis without mental symptoms, but he contended that this was a very difficult thing to do in any form of insanity. Without mental symptoms one could scarcely make a diagnosis of mental disease. He realized

of course that paresis had at the outset somatic symptoms which sometimes preceded the fully developed mental symptoms. He had long since come to regard paresis as an absolutely hopeless form of disease so far as recovery was concerned. He would be inclined to question the correctness of Dr. Dana's diagnosis made in the predevelopment stage of the disease if those patients fully recovered. The first case cited struck him as being a well marked, almost typical case of paresis, as regarded both the mental and the physical symptoms. He would regard the patient's declarations as evidence of a pronounced delusion; also that he was in a delusional state was shown both by his manner and his appearance as described. In his experience he had never known a complete and permanent recovery from true paresis. He had been led to doubt the diagnosis in many cases, but he had never known an authenticated recovery from paresis. Those cases that recovered were, in his opinion, not true paresis, but pseudoparesis, probably of the syphilitic or alcoholic variety. He understood Dr. Dana to say that he did not recognize pseudo forms of paresis, and he asked Dr. Dana how he would classify those cases which were described and so classified by many writers, in fact by most writers, as pseudo general paresis, either alcoholic or syphilitic. What term would Dr. Dana apply to those conditions? Sometimes he had deemed it wise to defer making a positive diagnosis pending the termination of a case. He was not prepared to agree with Dr. Dana that all cases of paresis were of syphilitic origin. In a considerable number of cases it was doubtless true that syphilis must be regarded as an ætiological factor, but there were a certain proportion in which syphilis did not enter as a cause. He could not understand how one would be justified in assigning syphilis as a cause in those cases in which there were no evidences whatever of syphilis in the history.

He quite agreed with Dr. Dana that occasionally, though rarely, the subjects of paresis improved, both mentally and physically, sufficiently to enable them to return to their homes and to resume their business and social relations for a time, but such persons, in his opinion, never made a full recovery, and, if the diagnosis was correct, the cases invariably relapsed and eventually terminated fatally.

Dr. WILLIAM HIRSCH thought that, up to the present time, the feeling in general was that general paresis was an incurable disease. He always took the standpoint when he came across a case that had been diagnosed as general paresis which, after a reasonable time, seemed to get well, that a wrong diagnosis had been made. He did not think this was the correct standpoint to take; we should not say *à priori* that cases were not general paresis because the patients got well. If such a standpoint was assumed, further progress would probably be prevented and but little or no further knowledge of the disease be forthcoming. We should be prejudiced, to say the least. Therefore he was thankful to Dr. Dana for bringing up this subject before the society.

The question whether general paresis in the early stages was a curable disease or not should not result in *à priori* statements before we had absolute evidence for calling it an incurable disease. So far as

the statements went concerning Dr. Dana's cases, he was inclined to agree with most of the gentlemen. He regarded the first case as one of remissions, and he did not agree with Dr. Dana that with these remissions the patients might recover so long as these remissions remained; he regarded the remissions only as partial recovery. Dr. Hirsch had known of cases where the remissions had been such that one could not have found any fault regarding the mental or physical condition of the patients. He had one patient in mind who had been treated in an institution many years ago. The patient was an officer in the German army and had a well marked general paresis. He had all the classical symptoms. He was engaged to the daughter of a general. After six months he got his remission; they were such that his family insisted upon his going home, and he was, therefore, discharged. The family was told regarding his condition, that he was not cured, but only had a remission. He asked permission to marry, but did not seek medical advice. He married and remained apparently well for a year, and his wife gave birth to a healthy child. After a year the disease developed and he died within a year, of general paresis. During this one year he had been perfectly well, all the somatic and mental symptoms having entirely disappeared. This was only one of many cases that he could report where the remissions had been such that nobody could find any symptoms of any kind. The minds cleared up perfectly. He believed that one should be extremely careful in drawing any conclusions as to the curability of the disease, and he believed one should demand that three or four years should elapse before one was entitled to draw any conclusion that the disease had been cured.

In Dr. Dana's second case one should think of the diagnosis between general paresis and lues cerebri, and this was often very difficult. Some cases presented all the classical symptoms of cerebral syphilis and some of cerebrospinal meningitis. One of the chief distinguishing points related to the reflexes; when there was a difference in the patellar reflex the point was in favor of syphilis. In general paresis the patellar reflex was exaggerated or absent. The same applied to the pupil reflexes. The diagnosis of general paresis and of syphilis was extremely difficult, especially during the early stages. If a patient got well under antisiphilitic treatment, he would always leave it open whether the case was one of cerebrospinal syphilis; he would be inclined to believe that it was, and not a case of general paresis. He was a firm believer in the importance of syphilis as an aetiological factor in these cases, but undoubtedly there were cases of general paresis in which there was no history of syphilis at all. He referred to a lady from San Francisco who had general paresis; in this instance it could be proved beyond a doubt that there was no history of syphilis. He knew of several cases where syphilis not only was denied, but it could be proved that it was not present.

So far as a diagnosis was concerned in the first stages of general paresis, he did not agree with those who stated that there should be a demand of mental deterioration at the start; the deterioration of the mental faculties was a consequence of general paresis, i. e., it developed at a later stage of the

disease. If it was necessary to demand a mental deterioration in making a diagnosis of the early stages of the disease, one could never make such a diagnosis. He believed that the gentlemen were, as a rule, proud of the accomplishment of making an early diagnosis of general paresis so much earlier than they did twenty or thirty years ago. But one should not make such a demand as a marked deterioration of the mental faculties in making a diagnosis during the early stages of the disease. Nevertheless, the question should be left open whether or not general paresis might not be curable. For that reason we should not assume the standpoint of saying that when cases were cured they must be seen in the early stages.

The CHAIRMAN said that, so far as his experience went, he had never seen a case of true general paresis cured. The cases that had ended in recovery had been those of alcoholism, the pseudoparesis of Fournier, and obscure examples of drug habits. He could not imagine such serious conditions as those described by Dr. Dana, with profound organic changes and generally absent deep reflexes, where the treatment employed or any other could have given such astonishing results.

Dr. DANA believed that a more conservative view must be taken of the question of the curability of paresis, and he thought that most of the criticism of his position had been based upon misapprehension. He used the term cured or arrested with reference only to the earliest stage of paresis, a stage to which the term "preparetic" might be applied. He had seen personally a large number of patients in whom the symptoms described in his paper occurred, but these had gone on and developed general paresis in spite of treatment in some cases, or without any treatment in others. If one would go back in the history of patients two or three years before the patients reached a hospital, one would find, in a considerable proportion of cases, that they had precisely the same conditions as he had described in his paper; and he believed that it was the duty of psychiatrists and neurologists to be able to recognize the condition in the early stages, when it was possible to stop the progress of the disease. He did not believe they were able to stop the disease in any case unless it was diagnosed early. He did not maintain that the cases he reported were real cases of general paresis as ordinarily described, but only that they would become so. He agreed with Dr. MacDonald that when paresis was in full bloom it was an incurable disease. He hesitated to bring up the subject of the relation of paresis to syphilis, because he thought the subject was a closed one. He believed that it was generally accepted that syphilis had the same relation to paresis as it had to tabes. Every year the proportion of cases of syphilis and paresis increased and, for practical purposes, syphilis might be considered the chief factor in its production.

Regarding pseudoparesis of alcoholic and syphilitic origin, he did not think the diseases were the same. In alcoholic pseudoparesis there was a sort of chronic mental deterioration, or dementia, and he preferred to call these cases alcoholic dementia rather than use the term paresis, because they did not present any close resemblance to the picture of paresis. Syphilitic pseudoparesis was really an

exudative cerebral syphilis taking the form of meningitis or arteritis. Most cases of so called syphilitic pseudoparesis sooner or later developed into a true paresis. Some of the cases, he thought, had better be termed organic dementia of syphilitic origin. Degenerative processes were not always progressive. He had even seen cases of progressive muscular atrophy of a typical kind arrested for years.

Dr. CLARK asked Dr. Dana how a knee jerk that was lost in tabes or general paresis could return. In such cases he believed there was a degeneration of the neuroperepheral nerve fibres.

Dr. DANA replied that this was a clinical fact and that it was explained probably by the fact that there was a syphilitic lymphangitis or exudate causing a loss of knee jerk; when this was absorbed this reflex returned.

Dr. HIRSCH asked Dr. Dana regarding the return of patellar reflexes. Much had been written on this subject, and all held that the return of patellar reflexes was an absolute sign of syphilis, as this only returned in syphilitic cases. This was explained pathologically by Oppenheim by the fact that all cases of spinal syphilis caused a meningitis, and the disturbance of reflex mechanism was a secondary process produced primarily by the lesion in the meninges. The syphilitic treatment caused a resorption of the injurious exudate, and then occurred a return of the patellar reflexes. Clinically, they all agreed that the return of the patellar reflex was a sign of syphilis.

The CHAIRMAN had seen cases of alcoholic toxæmia where the reflexes disappeared and then returned.

Dr. CLARK thought that Dr. Dana's cases were purely degenerative, and he asked if he believed there was this central degeneration.

Dr. DANA replied that in tabes sometimes there was both a degeneration and an exudation; the anti-syphilitic treatment would remove the latter, and the reflexes would then be restored.

Dr. MACDONALD assumed that the symptoms of true paresis were both outward expressions of organic disease in the central nervous system, that is, in the central cortex, and, if this was so, would it not follow that the condition would necessarily be one from which recovery was impossible? He would like to ask Dr. Meyer if this was not true from a pathological standpoint.

Dr. MEYER said that was the burning question, especially since the investigations of Alzheimer and others had divided off a new process as a diffuse cerebral syphilis, distinct from the condition of a general paralysis process. Since these investigations the whole situation had been made more complex. His sentiments went in the direction of Dr. Dana's, and he thought we should be prepared to give all our attention to therapeutics, even though general paralysis was probable, and we should at least strive for a remission as if the disease could be cured. Whether these really curable conditions were accompanied by the typical changes of paresis and verifiable anatomically, he had serious doubts. On the other hand, he had not had any cases of general paresis that he could vouch for clinically that had not shown definite changes in the central nervous system, organic changes with participation in them

of blood vessels, neuroglia, derangement of certain elements in the cortex, etc. He had, however, in mind a patient of Dr. Howard's, at the Rochester State Hospital, who had "general paresis" for two years, and then passed into a paranoiac condition, with marked expansiveness and some paralytic symptoms of inconsistency, etc. The patient also had a convulsion once. When he was examined by Dr. Meyer, a few months before he committed suicide, there were still a certain number of symptoms that could safely be classed as belonging to general paresis. In this case there was only a residuum of the disease process to be found, both clinically and on microscopical examination. We must further admit that occasionally we did see cases of a protracted type, cases of general paralysis that could truly be described as "progressive" general paralysis, cases that became arrested from ten to fifteen years or even more. Hence we should not, *à priori*, exclude the possibility of a lasting remission at the outset.

Dr. DANA said that if we could recognize the earliest symptoms of general paresis, we might be able to arrest the process and the patient might become practically a healthy man, i. e., if the brain cells were not sufficiently destroyed by the parietic process to interfere with a sound mental action.

Dr. MEYER said that Nature was evidently vicious regarding that point. The important point about general paresis seemed to be that of finding out what made general paresis a progressive disease. If one could determine that, much would be gained. But at present nothing of that sort was at hand.

Dr. DANA argued that we had an allied condition in tabes; in tabes the disease process could be arrested and the patient have no more than simple tabetic pains.

Dr. HIRSCH believed that in general paresis, as well as organic diseases, the clinical symptoms preceded what was called the anatomical changes. It was a fact that in the very early stages, when the clinical symptoms were developing, the microscope did not reveal changes in the tissues.

Book Notices.

Lehrbuch der Arzneimittellehre und Arzneiverordnungslehre. Unter besonderer Berücksichtigung der deutschen und österreichischen Pharmakopoe. Von Dr. H. v. TAPPEINER, ord. Professor der Pharmakologie und Vorstand des pharmakologischen Instituts der Universität München. Fünfte neu rearbeitete Auflage. Leipzig: F. C. W. Vogel, 1904. Pp. viii-347. (7 M.)

In this fifth edition of Professor von Tappeiner's work there is a careful revision, with a judicious selection of the newer materials, which affords in a relatively small compass a reliable guide to materia medica and prescription writing. In considering the different drugs a therapeutic classification has been adopted, and a useful feature has been the appending after each group of a few model prescriptions. In these the metric system has been used throughout. There is a conservative and well written chapter on organotherapy and serumtherapy which deals sufficiently with the proved facts of

value, but which does not carry the student too far afield in the domain of mere speculation. In the section devoted to the therapeutics of iron a healthy skepticism is shown regarding the alleged superiority of the numerous organic preparations. The work is adapted to the German and Austrian pharmacopœias, and this will necessarily limit somewhat its usefulness in this country.

A Textbook of Quantitative Chemical Analysis. By Gravimetric, Electrolytic, Volumetric, and Gasometric Methods, with 72 Laboratory Exercises, giving the Analysis of Pure Salts, Alloys, Minerals, and Technical Products. By J. C. OLSEN, A. M., Ph. D., Professor of Analytical Chemistry in the Polytechnic Institute of Brooklyn, formerly Fellow of the Johns Hopkins University. New York: D. Van Nostrand Company, 1904. Pp. xix-513. (\$4.00 net.)

The author states in his preface that the present work has been prepared chiefly to meet his own needs in presenting the subject to his students. In furtherance of this, the arrangement and presentation of the subject matter meet the needs of the student rather than those of the experienced analyst. The author has had considerable experience in the teaching of chemistry at the Brooklyn Polytechnic Institute. Rather less space than we expected is given to the theory of solutions, the ionic theory of electrolysis being rather briefly treated of in a chapter on electrolytic methods. In addition to its value as a textbook, Dr. Olsen's work should serve as a reference book for the professional chemist, and we regard it as a useful addition to the literature of chemistry.

First Report of the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. By the Director, ANDREW BALFOUR, M. D., B. Sc., etc., Fellow of the Royal Institute of Public Health, Member of the Epidemiological Society, etc. Khartoum: Department of Education, Sudan Government, 1904. Pp. iii-83.

In this instance the munificence of Mr. Henry S. Wellcome has enabled Egypt to have the services of so excellent a man as the director of the Research Laboratory of the Gordon Memorial College. There is an interesting account of the purposes and organization of the laboratory.

Before reaching Khartoum, the director was told that malaria did not occur there and that the *Anopheles* was unknown. Both these statements were found to be erroneous, and there is an account of mosquito work in the city and the Sudan. There are descriptions of biting and noxious insects other than mosquitoes, and of insects and vegetable parasites injurious to crops.

The printing is most creditable to the Department of Education of the Sudan Government, and the work is well illustrated.

The Alumni of the Medical Department of Dartmouth College are raising a fund of \$30,000 for the enlargement of the medical building. More than half of the money has already been raised, and it is hoped to begin work in the spring.

Miscellany.

Cancer of the Upper Portion of the Rectum.—Girard, in the *Revue de chirurgie*, for November 10, 1904, calls attention to the fact that cancer may be located so high in the rectum as to be beyond the reach of the examining finger, and may require abdominal palpation for its determination. An early diagnosis is difficult under this condition, and becomes still more so when the symptoms are few and inconspicuous. A bloody or mucous diarrhoea may not occur very frequently, constipation or obstruction may be wanting, and it would be reasonable to suppose that one was dealing with an ulcerative colitis.

At a later period perforation into the bladder may take place, with accompanying pneumaturia or fecaluria, or into other adjacent organs, and symptoms may be presented which make the diagnosis of cancer clearly evident. At such a time a radical operation would be useless and the best that can be done will be to form an artificial anus in the iliac region. In one of the author's cases the disease had remained latent a long time and had then caused an abscess to develop in the cæcovesical region with the usual phenomena of suppurative appendicitis and subsequently with perforation of the large intestine and the bladder. An artificial anus was made and a loop of the perforated intestine was excluded.

It may therefore be very difficult to recognize the nature and the exact situation of this disease until after complications have supervened. It may be necessary to perform an exploratory laparotomy, but before this is done one should make an examination with the rectosigmoidoscope or Strauss or some similar instrument. In one of the author's cases the patient himself suspected the condition and examined his stools with such thoroughness that he finally discovered a portion of tumor which when examined microscopically proved to be cancerous. An abdominal section was made and the diseased segment of rectum excised. The patient has remained without recurrence and without bad symptoms of any kind for more than two years.

Syphilitic Synovitis in Children.—Dunlop, in the *Edinburgh Medical Journal*, for December, 1904, thinks this disease is not so rare as has usually been supposed, and that it has often been overlooked, or treated as tuberculosis or rheumatism. It may be either congenital or acquired. The author classifies the disease as follows:

1. Cases which occur in infants subsequent to an epiphysitis by continuity.
2. Those in which a chronic effusion takes place into one or more joints, especially the knees, between the ages of 8 and 15 years, and in which the synovitis is the primary and chief affection. Both these forms are congenital.

Degenerative changes take place in the bones and cartilage with or without deformity. Suppuration into the joint may occur and the periosteum may be greatly thickened. The symptoms are those of inflammation and develop rapidly. The elbows, wrists, knees, and ankles are most frequently involved, both members being affected

at the same time, though the disease may be more severe in one than in its fellow. The prognosis is favorable if treatment is begun soon after the disease makes its appearance, especially if only one joint is involved. These symptoms refer to the disease as it occurs in infants who are the subjects of congenital syphilis, and they usually appear during the first three months of life.

In the second variety of this disease the most striking features are its insidious development, its chronic course, its symmetrical distribution, its freedom from pain and the mobility of the joints on passive movement; its association with other syphilitic stigmata, its amenability to treatment, and its tendency to relapse. The knees are most frequently affected, one usually more than the other. There is swelling from synovial effusion, but little or no pain or disturbance of function. It is often associated with other late symptoms of hereditary syphilis, especially with keratitis. Hutchinson's teeth, deafness, and nodes on the long bones are frequent accompaniments.

The condition seems to be a subacute synovitis caused by the syphilitic poison and without distinctive pathological lesions, but in some cases there are infiltration, hyperæmia, and gumma of the synovial membrane. Nodes may be felt in the capsule of the joint. Under treatment the new tissue undergoes absorption and organizes with thickening of the joint.

The diagnosis is based upon the bilateral effusion, the absence of pain, and the small amount of functional disturbance. The presence of other syphilitic stigmata, and improvement under anti-syphilitic treatment confirm the diagnosis. Treatment by rest, counterirritation, splints, and other measures used in simple synovitis have little beneficial effect. Improvement is usually rapid when mercury and iodide of potassium in combination are administered. Sublimate baths and the local use of mercurial ointment are also very efficient. A case may resist all forms of treatment for months and suddenly recover. The disease is very apt to recur if treatment is discontinued.

Remarks on Diseases of the Pancreas.—Bardenheuer, in *Fortschritte der Medizin*, for October 1, 1904, reports two cases which he calls acute interstitial pancreatitis, and which he was able to cure by means of an incision made on the right side of the body. In the first case there had been an injury, a fall on the right side against the edge of a beam having been experienced. Abdominal section having been performed, new growths of the stomach were found, especially in the region of the pylorus. The stomach was dilated, and so was the duodenum in its upper portion, the head of the pancreas was much enlarged, hardened, and hyperæmic, while the remainder of the pancreas was atrophic, pale, and fatty. The growths of the stomach were removed, a gastroenterostomy was performed, and the patient recovered. In the second case there were violent attacks of apparent cholelithiasis. A median section was made above the navel. Behind the stomach and the gastrocolic ligament a fluctuating tumor was observed, but there was no fatty necrosis. When the tumor was opened a quantity of blood and fluid resembling coffee grounds was evacuated.

At the back part of the cavity the pancreas of firm consistency and overlaid with necrotic tissue could be felt. Subsequently a fistula of the pancreas developed, from which there was a discharge of fluid containing trypsin. This fistula continued to discharge for several weeks, and necessitated the exposure of the pancreas by a lumbar section. In this operation the spleen was laid bare and extensive exudate was discovered in which the pancreas was embedded. The fistulous tract leading to the pancreas was defined, ligated, and divided with the Paquelin cautery. A cure resulted. The author believed that the acute pancreatitis in this case was due to changes in the vessel walls. The patient was very fat and gave a history of syphilis. An early operation in such cases, when there is a suspicion of hæmorrhage from the pancreas, should be performed in order to forestall fatty necrosis or peritonitis.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending January 13, 1905:

Smallpox—United States.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending January 11, 1905:

ATILES, PEDRO DEL VALLE, Acting Assistant Surgeon. Granted leave of absence for seven days from December 26, 1904, under paragraph 210 of the regulations.

BLUE, RUPERT, Passed Assistant Surgeon. Detailed as inspector of unseviceable property at the marine hospital, San Francisco, Cal. January 7, 1905.

EDWARDS, J. W., Acting Assistant Surgeon. Granted leave of absence for twelve days from December 20, 1904, and three days from January 1, 1905.

FRICKS, L. D., Passed Assistant Surgeon. Relieved from duty at La Guayra, Venezuela, and directed to proceed to New York, N. Y., and report arrival by wire. January 9, 1905.

GIBSON, F. L., Pharmacist. Leave of absence granted Pharmacist Gibson for thirty days from January 1, 1905, amended to read ten days from January 1st. Relieved from duty at Honolulu, T. H., and directed to proceed to San Francisco, Cal., and report to Medical Officer in Command for duty and assignment to quarters, relieving Pharmacist Charles Slough. January 4, 1905.

JACKSON, J. M., JR., Acting Assistant Surgeon. Department letter of December 8, 1904, amended so as to grant Acting Assistant Surgeon Jackson leave of absence for nineteen days instead of thirty days from November 26, 1904.

KORN, W. A., Passed Assistant Surgeon. Bureau letter of December 27, 1904, granting Passed Assistant Surgeon Korn leave of absence for seven days, amended so that said leave shall be for four days only.

SLOUGH, CHARLES, Pharmacist. Upon being relieved from duty at San Francisco, Cal., by Pharmacist F. L. Gibson, to proceed to Honolulu, T. H., and report to Chief Quarantine Officer for assignment to duty. January 4, 1905.

STEARNS, W. L., Pharmacist. To proceed to Washington, D. C., for special temporary duty. January 4, 1905.

TUTTLE, JAY, Acting Assistant Surgeon. Granted leave of absence for thirty days from January 9th.

WERTENBAKER, C. P., Surgeon. To report at Washington, D. C., for special temporary duty. January 10, 1905.

WETMORE, W. O., Acting Assistant Surgeon. Granted leave of absence for ten days from January 4th.

WHITE, J. H., Surgeon. Granted leave of absence for six days from January 17th.

Casualty.

Pharmacist F. R. HANRATH died at Cleveland, Ohio, January 7, 1905.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 14, 1905:

TAYLOR, J. S., Passed Assistant Surgeon. Detached from the Relief and ordered to the Ohio.

YOUNG, R. M., Assistant Surgeon. Resignation accepted, to take effect on January 21, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending January 14, 1905:

CHIDESTER, W. C., First Lieutenant and Assistant Surgeon. Left Fort Lawton, Wash., on ten days' leave of absence.

EBERT, R. G., Major and Surgeon. Left Vancouver Barrack, Wash., en route to Fort D. A. Russell, Wyoming.

MORSE, A. E., First Lieutenant and Assistant Surgeon. Ordered to accompany Field Artillery to San Francisco, Cal., and then to return to post.

REILLY, JOHN J., First Lieutenant and Assistant Surgeon. Left Jackson Barracks, Louisiana, en route to the Army and Navy General Hospital, Hot Springs, Ark., for treatment.

STILES, HENRY R., Captain and Assistant Surgeon. Ordered to report to William H. Arthur, Major and Surgeon, president of the examining board, on January 17, 1905, at Washington, D. C., for examination for promotion.

Births, Marriages, and Deaths

Born.

PURNELL.—In Camp McGrath, Batangas, Philippine Islands, on Tuesday, November 1st, to Dr. Harry S. Purnell, United States Army, and Mrs. Purnell, a son.

Married.

BUSHON—DULANEY.—In Baltimore, Maryland, on Tuesday, January 3rd, Dr. John Henry Bushon and Miss Edith Roy Dulaney.

LOWES—MCKNIGHT.—In Mount Forest, Canada, on McMurdo—LE DUC.—In Philadelphia, on Wednesday, January 11th, Dr. Percy Fitzgerald McMurdo, United States Navy, and Miss Genevieve Le Duc.

WILSON—RADDANT.—In New York, on Saturday, December 24th, Dr. Arthur Starkey Wilson and Miss Metha Elizabeth Raddant.

Died.

CARMALT.—In New York, on Sunday, January 8th, Dr. Churchill Carmalt, in the fortieth year of his age.

CONVEY.—In Brooklyn, N. Y., on Saturday, January 7th, Dr. George V. Convey, in the forty-fifth year of his age.

COX.—In Nashville, Tennessee, on Friday, January 6th, Dr. W. R. Cox, in the eighty-ninth year of his age.

DAVIS.—In Brooklyn, N. Y., on Sunday, January 8th, Dr. William Harper Davis, in the thirty-third year of his age.

D'HOMERGUE.—In Brooklyn, N. Y., on Thursday, January 12th, Dr. Louis C. D'Homerque, in the sixty-eighth year of his age.

ELLISON.—In Benton Centre, N. Y., on Tuesday, December 20th, Dr. Albert Ellison.

ILIFF.—In Philadelphia, on Wednesday, January 11th, Dr. John Pearson Iliff, in the fifty-fifth year of his age.

LANDRUM.—In Mayfield, Kentucky, on Monday, January 9th, Dr. James D. Landrum, in the eighty-third year of his age.

MANLEY.—In New York, on Friday, January 13th, Dr. Thomas H. Manley, in the fifty-fifth year of his age.

McCORMICK.—In Yazoo City, Mississippi, on Tuesday, January 3rd, Dr. P. J. McCormick.

MERRIWETHER.—In Mathews, Alabama, on Sunday, January 1st, Dr. John Lucas Merriwether, in the fifty-sixth year of his age.

MILLER.—In Collinsville, Alabama, on Saturday, December 10th, Dr. J. Taylor Miller, in the fifty-eighth year of his age.

OATIS.—In Hazelhurst, Mississippi, on Friday, January 6th, Dr. C. E. Oatis.

TYGESSON.—In Hartford, Connecticut, on Friday, January 6th, Dr. Alfred Tygesson.

WELLS.—In New York, on Thursday, January 12th, Dr. Henry Martin Wells, retired medical director of the United States Navy, in the seventy-first year of his age.

New York Medical Journal AND Philadelphia Medical Journal.

THE RELATION OF RADIOGRAPHIC APPEARANCES TO CLINICAL SYMPTOMS IN HIP DISEASE.*

By ROBERT W. LOVETT, M. D.,

BOSTON,

ASSISTANT SURGEON TO THE CHILDREN'S HOSPITAL, BOSTON,
AND

PERCY BROWN, M. D.,

BOSTON,

RADIOLOGIST TO THE CHILDREN'S HOSPITAL AND TO THE
CARNEY HOSPITAL

The following investigation was undertaken by the writers to determine what value radiographs possessed taken by themselves in the diagnosis of hip disease, and especially in the detection of early disease. In order to form a perfectly unbiased opinion each negative was examined by the writers and recorded by number and an opinion written in each case as to whether disease was present and as to the character of such disease. In doing this the writers were at that time ignorant of the name of the patient and of the clinical diagnosis. The clinical history was later looked up and the value of the opinion formed from the radiograph tested in this way. The correspondence of the x ray opinion and the clinical diagnosis and history were then recorded in each case. One hundred consecutive negatives of the hip joint were taken from the files of the Children's Hospital x ray department and investigated by this method. The writers are indebted to their colleagues for permission to report all cases coming to the x ray department.

It may be said that this method of examination brought the writers in contact with practically every obscure and difficult case of trouble in the hips that had been seen at the hospital in the last three or four years, for such cases were likely to be x rayed, whereas routine cases might not be. One fact is clear, already brought out by one of the writers¹ in a former paper, that there are

certain cases of lameness and disability in the hips that do not fall in clinically with tuberculous disease, and whose x ray appearances are no more definite than the clinical. They are classed in the doubtful cases.

The following questions were formulated at the beginning of the inquiry:

1. What proportion of cases diagnosticated as hip disease from the x ray, presented a typical clinical history, and what proportion of such cases did not have such a clinical history?

2. What was the later history of cases diagnosticated as normal from the x ray?

3. How late in the history of hip disease does a "normal" radiograph appear?

4. What are the characteristic appearances of the radiograph in hip disease?

5. What radiographic appearances go with shortening and deformity?

6. What similar conditions are found which the radiograph will differentiate from hip disease?

7. What are the sources of error in diagnosing hip disease from the radiograph?

The one hundred cases classed by the opinions expressed from the examination of the radiographs may be tabulated as follows:

	Cases.
"Normal" or "negative".....	20
"Hip disease" or "probable hip disease".....	61
"Old hip disease".....	4
"Destructive disease, not tuberculous".....	2
"Coxa vara".....	2
"Doubtful" or "questionable".....	4
"Abnormal, but not hip disease".....	2
"Probable hip disease" (proving to be abscess of groin)	2
Various diagnoses not borne out by clinical history.....	3

100

Normal appearances in the radiograph, 20 cases.

Eight cases proved to have been radiographed for other affections, such as Pott's disease or stone in the bladder, and the hips were included incidentally.

Seven cases were radiographed for suspected disease, but recovered so speedily that the affection was probably synovial.

* Presented at the meeting of the American Orthopaedic Association, Atlantic City, June 9, 1904.

¹ R. W. Lovett, *The Diagnosis of Hip Disease*, *Boston Medical and Surgical Journal*, August 14, 1902.

Two cases with a normal radiograph showed a typical history of hip disease.

In one of these (319) the duration of the disease at entrance had been six months, and in a year from the time of the radiograph, shortening and marked disease were present. In the other (71) some disability had existed for a year at the time of the radiograph, but clinical symptoms did not warrant a diagnosis. Two years after the radiograph, the patient had atrophy and permanent flexion, but no shortening.

Three cases with normal x ray appearances pursued a history not characteristic of hip disease. One (1179), four months after the radiograph, had some limitation of motion, but no shortening or atrophy. The second (154), a few months later, had motion to a right angle and no shortening, and a clinical diagnosis was withheld. The third (209) had atypical symptoms, and was diagnosed as rheumatism.

To judge then from these cases, the fact that the radiograph is normal is of much significance and should make one delay about diagnosing hip disease in such cases. The fact that the disease had been of six months' and a year's duration, in the cases where true hip disease existed with a normal radiograph, is not easy to explain.

HIP DISEASE.

Sixty-one cases were diagnosed as hip disease from the radiograph, in which the clinical history was typical and the subsequent course of the affection confirmed the opinion formed from the radiograph. The chief importance of these cases lies in the description of the signs in the radiograph upon which this opinion was based.

The various radiographic appearances seen in tuberculous disease of the hip are characteristic of this affection when taken collectively. Any one of them may be a factor in making up the Röntgen pictures of other pathological conditions, but, considered in combination, they tell a consistent story of a process in which tuberculosis is the (chief) causative factor.

In the early stages of the disease, when sensitiveness, pain on motion, and muscular spasm are usually well marked, it is often impossible to differentiate the Röntgenographic plate from that of a normal joint. With the onset of limitation of motion due to spasm, however, evidences of atrophy generally set in, and there appear for inspection the phenomena about to be described. These appearances vary, naturally, with the extent and duration of the disease, beginning with evidences of simple atrophy, passing on to bony thickening, erosion, cavity formation, and loss of

substance, to complete absorption, destruction, and ankylosis. These will be taken up seriatim for the purpose of clearer description.

I. ATROPHY.

The earliest changes seen in the radiograph are (a) diminution in the density of the shadow and (b) a relative diminution in the size of the shadow cast by the affected bone. Where one form of atrophy exists, the other is likely to be found. In one case observed by the writers a radiograph showed no abnormal appearances, but a second radiograph taken six weeks later showed a diminution in the density of the shadow of the affected hip, but no diminution in the size of the shadow. Of course, all that has been said as to relative density and size of shadow presupposes attention to proper technique in making the exposure.

(a) *Diminution in Density of Shadow.*—Exposed to Röntgen radiation, bone affected by early tuberculosis makes a photographic impression best described as "increased radiability." The shadow is thin and foggy and contrasts feebly with the surrounding soft parts. The shadow of the bone cortex is relatively a strong one, and stands out sharply from that of the medulla. The fine trabecular shadows stand out in the mass of thin fog, which fills the bone area. These appearances are clearly due to a photographic overexposure in the bone shadows caused by the lack in the bone of elements such as the calcium salts, which would normally offer a greater resistance to the passage of x radiation. The presence of increased radiability is usually more noticeable in the bones of older children or adults, where the proportion of calcium is normally greater.

(b) *Diminution in Relative Size of Shadow.*—The atrophy in size may be seen most strikingly in the pubic bone, lying in juxtaposition to its healthy fellow, in cases of unilateral disease. The atrophy of size is less evident in the head and neck of the femur, its presence there being often concealed by compensatory bony thickening.

Atrophy of both types involves most often the upper shaft of the femur, the acetabular portion of the ilium, and the os pubis.

As the radiographic evidences of bone atrophy are seen also in fractures where the circulation is impeded, in gonorrhœal affections, in various palsies, and as a manifestation of hereditary syphilis, each of these conditions must be ruled out if the radiographic plate presents atrophy alone.

As the majority of negatives examined by the writers were taken at other than the earliest stages of the disease it has been unusual in this

1.—Early stage of hip disease of joint on right of picture. Increased radiability of neck of femur.

FIG. 2.—Early stage of hip disease of joint on right of picture. Same appearances as in Fig. 1, with involvement of acetabulum.

FIG. 3.—Femoral and acetabular disease of joint on right of picture. Slight atrophy and increased radiability of epiphysis. Thickening of base of acetabulum.

FIG. 4.—Femoral disease of joint on right of picture. Erosion of head, thickening of neck, atrophy of bones.

FIG. 5.—Old hip disease of joint on left of picture. Ankylosis and atrophy. Gant osteotomy for deformity.

series to find atrophy alone, but generally with it the changes later to be described.

II. BONY THICKENING.

This is the best radiographic evidence of Nature's efforts at repair, and is most often seen, in the plate, to involve the neck, and less often the head of the femur. The writers have observed in this series of cases a shadow, projecting in from the pelvic side of the acetabulum; in the majority of cases in which this appearance presented itself, acetabular disease had been diagnosticated clinically.

III. DECREASED RADIABILITY.

Apart from the photographic fog seen in negatives presenting increased radiability, there may often be observed an indefinite cloudy appearance, which involves not only the bony medulla, but the cortex and periosteal structures as well. In cases of tuberculous coxitis, this cloudiness has been found by subsequent clinical experience to be due to the presence of thick serum, pus, or finely divided detritus. The occurrence of this form of decreased radiability without other evidence is often misleading and the writers have observed it in cases where the process was extra-articular, such as abscess of the groin.

IV. EROSION.

Where actual loss of bone substance exists in a hip, it is usually clearly evident in the plate, varying in all degrees from irregularities of the articular surfaces to the formation of cavities and vacuoles or complete destruction and absorption. Since the presence of these appearances alone is not sufficient evidence upon which to make a diagnosis, radiographically, of tuberculous hip disease, it becomes necessary, as before stated, to search for some other coexistent photographic appearances, such as have been above described.

"*Old*" hip disease was a diagnosis made four times from the x ray negative where the process was advanced and evidently of long standing. This opinion was borne out by the clinical history.

Destructive disease not tuberculous was an opinion expressed in two cases. In one (48) the diagnosis of osteomyelitis of both hips was borne out by the history. The second (124) proved to be a hip following typhoid.

Coxa vara was found in two cases and the clinical diagnosis was the same.

Probable hip disease was the opinion in two cases where the suggestion of the disease was conveyed by a very slight haziness about the joint. It was so slight that no opinion more positive than this was expressed. Examination of the

records showed that these cases had suffered from an acute abscess of the groin in no way connected with the hip, and that the cloud seen in the radiograph was undoubtedly due to the resistance to the rays offered by the pus lying superficial to the joint.

Questionable was the opinion expressed in four cases. In one (530) there were atrophy, thin shadow, and broadening of the joint line. The clinical diagnosis had never been made, although some disability in the hip had existed for years. In another (13) there was slight atrophy with some enlargement of the head and neck. The symptoms had disappeared in two months. In a third (663) there were thickening of the head and neck, and dislocation. Clinically there was a history of a limp of long duration and of a one inch shortening. No clinical diagnosis was made. In the fourth (721) there was slight atrophy with thickening of the head. The history was atypical and the boy speedily recovered.

It is interesting to note that the radiographic appearances in these cases were much alike, consisting chiefly of atrophy and enlargement of the head and neck of the femur.

Not hip disease, but not normal, was the opinion in two cases (748 and 752). The x ray appearances were slightly increased radiability and nothing else. At the time of the x ray examination both cases were suffering from some acute affection of the hip, but in a few weeks had wholly recovered.

In the other three cases, the x ray appearances did not agree with the clinical history. In two (58 and 520) what appeared to be marked signs in the hip went with the history of a slight affection, and in the third (496) an opinion was expressed that a destructive affection was osteomyelitis, while bacteriologically it had proved to be tuberculous.

Our conclusion as to the value of radiographs in the diagnosis of hip disease, and especially early disease, is that they are of great value in the hands of persons of average experience; that a radiograph free from abnormal appearances does not show that hip disease is absent or will not develop, but that in a case of doubtful clinical diagnosis a normal x ray is a matter of weight and makes the likelihood of speedy recovery greater than will radiograph with abnormal appearances.

The existence of slight atrophy of bone, and slight diminution of shadow, while on the other hand, not showing that hip disease was present in a case of doubtful clinical diagnosis, makes the likelihood of it greater and the outlook rather

more serious than a normal radiograph would do.

In only two cases was hip disease diagnosed where it was not present, and here the writers were misled by an extraarticular collection of pus. In three cases out of the hundred the opinion expressed was wholly wrong. In the remaining ninety-five, the opinion formed from the x ray was fairly well borne out clinically.

VESICORECTAL ANASTOMOSIS.

By BENJAMIN MERRILL RICKETTS, PH. B., M. D.,
CINCINNATI.

It has long been known that the urinary and alimentary tracts can be united during foetal, infant, or adult life in both animal and man by accident, disease, or surgical operation.

There are many conditions which require such an anastomosis for the purpose of diverting a part or all of the urine into the alimentary tract preferably into the sigmoid or especially the latter as low as possible, as the danger of kidney infection is lessened as the sphincter ani is approached.

While anastomosis in the following case was

FIG. 1.—Vesicorectal anastomosis from the vesical aspect. A, fundus of bladder; B, thickened bladder wall; C, sound emerging from bladder opening; D, undivided sphincter ani.

FIG. 2.—Vesical anastomosis from the rectal aspect. A, upper end of rectum; B, bladder; C and E, cut edge of sphincter ani; D, sound entering artificial opening in rectum.

purely accidental, resulting from pressure of the tube, it, together with its illustration, is appended, to show that it can and should be done in a certain class of cases.

The patient, aged sixty-seven years, had had prostatic hypertrophy for several years; on consultation with Dr. J. O. Blackerby, April, 1902, the bladder was found greatly distended, the urine dribbling, and the catheter could not be introduced through the urethra. There was no sugar, but there were albumin and pus in abundance.

The patient had been in bed two weeks, prepared to die at an early date.

Operation.—Under chloroform anaesthesia, a median perineal incision was made and the entire gland, together with its capsule, of twice the size of a guinea egg, was removed, the prostatic urethra included. About three and one half pints of thick, offensive urine with mucus escaped. An S shaped silver tube was introduced for drainage for several days, when urine was discovered to be escaping from the rectum, the flow from the incision gradually becoming less until at the end of ten months all the urine passed per rectum at intervals of three, four, and five hours.

The patient regained flesh and vigor and resumed his occupation (that of express agent). The urine caused no irritation of the rectum or any ill effect whatever, and the patient had com-

plete sphincteric control. The presence of pus and albumin continued until about January, 1904, when his physical condition became much impaired. He gradually failed until dissolution about May 10, 1904.

The necropsy was performed by Dr. Charles T. Souther and Dr. Blackerby eighteen hours after the body had been embalmed. There was marked emaciation, and rigor mortis was at its height. Examination was limited to the abdominal viscera. No omental adhesions were present. Inspection of intestines, liver, pancreas, spleen, and gall tract proved negative.

Nephritis was present in the right, and multiple abscesses were found in the left kidney. To prevent further mutilation, removal of the ureters was refused.

The bladder, together with the rectum and sphincter ani, were removed and the anastomosis was found to present the appearance shown in the illustrations.

There are many reasons to believe that infection of the kidneys antedated the removal of the prostate gland, and that the removal of the prostate prolonged life and made it more comfortable.

OVARIAN ANGEIOMA.

By BENJAMIN MERRILL RICKETTS, PH. B., M. D.,
CINCINNATI.

The rarity of ovarian angioma prompts the report of such a condition together with an illustration of the specimen.

Synonyms.—Angioma, erectile or vascular tumor. It may or may not be congenital and usually occurs in young girls.

In simple angioma the vessels are increased in number or size, or both, or their walls alone may be thickened by the formation of tissue elements. In this event angiomalacia with or without subsequent infection may occur. The ætiology and pathology are unknown.

CASE.—Miss P., white, aged fifteen years. At seven years of age she began to have pain in right lower pelvis. This continued, with irregular periodicity, until the age of fourteen years, when she menstruated for the first time. This occurred twice with increased severity and indication of appendicular disease. About this time she was operated upon for disease of the appendix, which was removed by a competent surgeon in one of the larger cities November 17, 1902. Pain of the same character and degree continued, especially before and during her irregular menstruation, until April 14, 1904, when I was called in consultation with Dr. J. H. Barker, who had seen her for the first time five hours before, suffering with severe pain in the right side. The diagnosis of

FIG. 3.—Dr. Ricketts's case of ovarian angioma.

ovarian hæmatoma was made and the abdomen opened in the median line three hours later, consuming fifteen minutes. The appendix had been removed without leaving any adhesions whatever. The belly had united perfectly. The left ovary was normal, but the right was found to be about the size of a guinea egg, and somewhat the shape of an acorn. The outer end was enlarged, red, and soft, and there were two deep rents in it due to the pressure incident to its removal.

This patient had been seen by Dr. Thomas Minor and Dr. William Gillespie several times from the age of ten to fifteen years. Dr. Gillespie had on several occasions administered veratrum viride which had always given relief. This is significant because of its influence upon the circulatory system. Recovery was uneventful.

Harvard Medical School Scholarships.—The faculty of the Harvard Medical School has announced the award of scholarships open to first year men as follows: The David Williams Cheever scholarship of \$250 to W. J. C. Sharpe, '04; the Lewis and Harriet Hayden scholarship of \$200 to E. D. Brown, University of Pennsylvania, '99; two Joseph Eveleth scholarships of \$200 each to H. S. Bernstein, '04, and F. H. McCrudden, Massachusetts Institute of Technology, '00; John Foster fund of \$50 to E. D. Bond, '00.

A NOTE ON BROWN-SEQUARD'S PARALYSIS, WITH REPORT OF A CASE IN WHICH THE PARALYSIS FOLLOWED A GUNSHOT WOUND IN THE NECK.*

By ALFRED GORDON, M. D.,

PHILADELPHIA,

INSTRUCTOR IN NERVOUS AND MENTAL DISEASES, JEFFERSON MEDICAL COLLEGE; ASSISTANT VISITING NEUROLOGIST TO THE PHILADELPHIA HOSPITAL; NEUROLOGIST TO THE DOUGLASS MEMORIAL HOSPITAL.

The symptom group obtained from a hemisection of the spinal cord had been known from the time of Galen; but Brown-Séquard, particularly in his classical description based upon clinical observations and numerous experiments, has given us an exact picture of the sensory and motor disturbances in mammifera; he had also shown that in man traumatic or other lesions which produce a breach of continuity of one half of the cord produce identical disturbances. In 1846, while experimenting on animals, like the dog, the rabbit, and the guinea pig, he noticed that a hemisection of the cord led to the following symptoms limited to the portion of the body which is innervated by the segment below the level of the section: (1) A motor paralysis of the side of the lesion; (2) an anæsthesia of the opposite side of the body. In addition to these main symptoms he observed also a few minor symptoms, viz.: (1) A hyperæsthesia of the paralyzed side; (2) a small band of anæsthesia situated immediately above the hyperæsthetic area; (3) also sometimes a narrow area of hyperæsthesia immediately above the anæsthetic band. Conjointly with the hyperæsthesia there is also (4) a distinct loss of muscular sense which is not present on the opposite side of the body; (5) exaggeration of tendon reflexes on the paralyzed side or even on both sides; (6) a vasomotor paralysis on the paralyzed side, which is shown by an increase of the temperature as compared with the opposite side; (7) finally, visceral symptoms (incontinence of urine and fæces); the latter depends upon the segment involved. When the cervical cord is injured, other symptoms will be observed in addition to those mentioned, namely: Disturbance of respiration, dilatation of the pupil on the side of the lesion, also enophthalmos (paralysis of the sympathetic nerve). This classical symptomatology which was observed on animals can also be observed in man, when the continuity of one half of the cord is interrupted either by a tumor or syringomyelia, or by a localized focus of myelitis or hæmorrhage (hæmatomyelia), by pressure from another source, or finally and

most frequently by a traumatic injury. The patient I have before you presents Brown-Séquard's syndrome, which made its appearance subsequent to a traumatic injury of the spinal cord. His history as taken at the Jefferson Hospital is as follows:

On the twenty-ninth day of December, 1903, patient was shot in the neck, the bullet penetrating the right side, posterior to the sternomastoid muscle in its middle third. There was no loss of

* The black portion indicates thermoanæsthesia and analgesia; the portion shaded in lines indicates thermohypesthesia and hypalgesia.

consciousness. Patient was removed to the Hahnemann Hospital directly after the accident, and two days thereafter was operated on for the removal of the bullet. Through the courtesy of that institution (3-26-04) the following facts were elicited from notes taken at the time the patient was under their care. Diagnosis: Gunshot fracture of the fifth cervical vertebra (Dr. Van Lennep). History of the illness: On Wednesday, December 30, 1903, at 2 a. m., patient was brought to the hospital with a wound in the region of the right side of neck close to the region of the jugular vein. The left pupil was larger than the right, but both reacted. The right lower extremity he could not move, and later the right upper extremity was also involved. The bullet wound was explored, but no trace of bullet was found. An incision was made over the cervical spines, the fifth cervical spine being found readily movable. The vertebral arch was pulled away with forceps,

* Read and patient exhibited before the Philadelphia County Medical Society.

as well as the transverse process on the right side. The track of the bullet was found to extend downward, entering the posterior mediastinum. The patient made a good recovery after the operation and was discharged February 13, 1904.

At present he presents a scar, surrounded by powder marks, over the region of the middle third of the sternomastoid muscle on the right side, and also a scar about 4 inches in length directly over the ligamentum nuchæ. Patient states that his right arm and leg were paralyzed. The leg began to improve on the twenty-fifth day after he was shot, so that now he is able to walk, although some dragging is noticed in walking. There is still some impairment in power of various portions of the affected limb. There is some foot drop, the knee jerks are markedly exaggerated, ankle clonus and Babinski's sign are distinct. No marked spasticity, however, is noticed. The right upper extremity is practically useless. About two months ago patient noticed returning motion in the little finger, which has improved, and he is now able to move the other fingers as well as to flex and extend the right hand at the wrist. The paralysis is flaccid, although there is some resistance to passive movement at the elbow. All the muscles of the upper extremity are somewhat wasted, but the atrophy affects particularly the supra and infraspinatus, the pectorales, and the trapezius muscles. All the tendon reflexes are exaggerated. On the opposite side of the body there is no indication of impairment of the motor power. The knee jerk, however, is somewhat exaggerated, and there is a doubtful Babinski's sign. Examination for sensations reveals the following peculiarities: While the sense of touch is preserved, the temperature and pain sense are very much impaired. The left upper extremity, beginning on all its aspects at a level of 14 cm. below the acromion, the thorax below the mamillary line, and the abdomen on the left, finally the entire left lower extremity on all its aspects, are totally thermoanæsthetic and analgetic. Above the mamillary line to the clavicle, also partly on the left side of the face, there is some diminution of sensations of pain and temperature. Over the deltoid muscle there is a slight hyperæsthesia, and immediately below a small area of hypalgesia. The disturbance of sensations is strictly and mathematically limited to the middle line of the body. The right half of the body is absolutely normal to all forms of sensation (see figure). The only sensory disturbance to notice on the right side is the astereognosis of the hand. The pupils are unequal, left larger than the right; slight drooping of the right eyelid; and slight enophthalmos is present on the right side.

To sum up, we have here a motor paralysis on the right side and a sensory paralysis on the left side. This is a symptom group which we observe in experimental physiology, when a hemisection of the spinal cord is made on animals. It is true that in the latter case we have a few additional symptoms, namely, a slight band of anesthesia on the paralyzed side, a vasomotor paralysis of the same side, visceral disturbances;

but these symptoms are not always present in man. Nevertheless, the fundamental symptoms concerning the localization of motor and sensory disturbances are present here in their entirety. It is therefore a case of typical Brown-Séquard's paralysis. A number of cases reported as examples of Brown-Séquard's paralysis do not all present the typical symptoms such as they were observed experimentally in animals; in some of them the paralysis is only partial, in some the sensory disturbances of the opposite side are not clearly cut. In fact, the pure type of this group of symptoms is rarely met with. In my case the main symptoms are present in their entirety and in the perfectly typical form, so that from a physiological standpoint it can be considered as one of exceptional value.

The morbid manifestations in traumatic hemisections of the spinal cord are limited to the lower extremities when the injury is below the ninth thoracic vertebra. In injuries at the level of the upper and middle thoracic vertebræ the thorax is also partly involved. An entire half of the body will show sensory and motor disturbances when the lesion is above the sixth cervical vertebra; in such cases there may also be present symptoms of paralysis of the sympathetic system. As in a large majority of cases the injury occurs in the thoracic region, the disturbances are usually confined to the lower extremities. My case, therefore, can be placed among those that are rarely met with. There are two points in the history of my patient's condition which deserve our attention.

An injury to the spinal cord is usually considered, with very good reason, of a very serious import because of the permanence of the lesions of the central nervous system; and in cases in which we suspect a hemisection we are naturally inclined to give the gravest prognosis. From a medicolegal standpoint it is highly important to be able to appreciate properly the true condition of the victim of an assault. It will be an error to think that when paralysis follows a hemisection of the cord, the patient will remain permanently incapacitated. The truth is that in a large majority of cases great improvement and even functional recovery follow. The reason of it lies in the question of regeneration of nervous elements, which in the state of our present knowledge is accepted as proved.

Clinical experience shows that in lesions below the sixth cervical vertebra the patient has great chances for improvement, while in cases above that level the prognosis should be reserved because of a possible appearance of disturbance of respiration. Our case is interesting from this

point of view, that the injury affected the cervical cord at the level of the fifth vertebra, and the patient escaped immediate serious trouble and even great improvement followed in the lower extremity.

It may perhaps be of some interest to see if our present knowledge of the fine anatomy of various tracts will explain the curious combination of symptoms. As to the motor paralysis in our case, it is easy to understand. A section or a lesion produced in the right half of the cord by the bullet injured the pyramidal tract below the decussation, as the injury was at the level of the fifth vertebra. The very same condition will explain the various reflex phenomena mentioned above (exaggerated reflexes, Babinski's sign, ankle clonus). Far more difficulty we experience in explaining the crossed hemianæsthesia. In order that a lesion of one side of the cord should give an involvement of sensations on the opposite side, we must suppose that either the sensory fibres themselves cross each other all along the cord or their collaterals decussate. Anatomy teaches us that the cells of the spinal ganglia send sensory prolongations which bifurcate: one branch is distributed at the periphery in the skin; the other branch serves to form the posterior root and enters the cord. The latter divides in the cord into two branches: one ascending (long), the other descending (short). These two do not decussate in the cord. The sensory impressions which come from the periphery are transmitted through these longitudinal branches, and also through the collaterals which those fibres give up. It is principally Ramón y Cajál that made us familiar with those collateral fibres. Among the latter there is particularly one variety that concerns us in the case under consideration, namely, the collaterals of the posterior commissure; after they have crossed the median line, they become distributed in the posterior cornua of the opposite side. The paths for sensations of pain and temperature are fibres coming from the posterior cornua of the opposite side. It is, therefore, evident that a destruction of one half of the cord will unavoidably produce a sensory disturbance on the opposite side. I hasten, however, to add that so simple as the question of sensory distribution may appear, it is far from being solved, as the anatomical data are not yet in entire accord with the clinical and experimental facts. In our case the pain and temperature sense are mainly involved. The lesion can, therefore, be approximately but with a great degree of probability placed in the right side of the cord affecting the pyramidal tract and the posterior cornu on the same side.

THE SIGNIFICANCE OF ABULIC SYMPTOMS IN CASES OF MENTAL DISEASE.*

By ROBERT H. CHASE, M. D.,

PHILADELPHIA,

SUPERINTENDENT, FRIENDS' ASYLUM FOR THE INSANE.

In presenting to you to-night a problem in psychiatry, I am conscious that in these days when the problems of medicine have grown so complex, one has little time to devote to the technical discussions of his neighbor, especially if they be in a field foreign to his own thought and study. Holding this in view, then, I shall endeavor to avoid a too formal presentation of my theme, hoping to gain your interest in some measure by calling your attention to a few special features of general application.

The term *abulia* designates, in a general way, a weakening or a diminution of the will force of the individual. It finds expression in hesitation, indecision, and in many forms of powerlessness, as well as in the defective energy of attention; in the normal state it is seen for instance in the inertia of convalescence and in the lassitude of spring-time. This mental inaptitude has long been familiar to physicians, who observe it in various forms of mental and nervous disease. Besides *hysteria*, where it strongly prevails, it is common in all of the forms in which the chief characteristic is inactivity of the mind. It is particularly conspicuous in *melancholia*, *dementia præcox*, and in the depressive types of general paresis; in some conditions of *neurasthenia* and *psychasthenia*; in the intoxication of opium and alcohol; in the retardation of manic-depressive insanity; in short, among patients generally suffering from weakness or exhaustion of the mental processes.

For the convenience of study the subject may be divided into systematized, localized, and general *abulia*. It is not my present purpose to go fully into these subdivisions, but only to point out some of the salient facts as we proceed. Systematized *abulia*, as the term implies, is not a lack of will power in general acts, but in a particular act or a system of special acts. It is not an easy task to differentiate systematized *abulia* with accuracy. The difficulty may be appreciated when one remembers that there are other ways by which a particular act may be suppressed, as in some instances by a fixed idea or in others by *amnesia*. In an elucidation of the question it is helpful to bear in mind that every volitional act contains two principal parts, *i. e.*, the sensory and motor. When an isolated act has passed out of memory, it is not easy to say which side of the arc is impaired. Certainly these phe-

* Read before the Philadelphia County Medical Society, December 14, 1904.

nomena "not-knowing" and "not-being-able," as they are called, are closely related, and in the normal man they are almost wholly confounded. But in certain mental cases we are obliged to make a distinction. A person who knows what should be done, but who cannot find in his mind the means of effecting it, who has simply forgotten the way of going about it, is not identical with the patient who does not give himself the trouble to conceive the act and makes no effort toward it. In the first instance he is amnesic, in the second, abulic. From a prognostic standpoint it is a matter of importance. As an example, *astasia abasia* is a form of amnesia of the motor images and not a form of abulia, properly so called. Some authors believe that the "not-willing" variety is met with more frequently in the generalized abulias and the "not-being-able" in the systematized forms. This is equivalent to saying that the latter are generally amnesias.

Of the systematized abulias Janet, an eminent French writer of the Charcot school, gives the abulia of sleep. This may seem odd to us for we do not generally speak of sleep as a volitional act, or connect it in any way with the will. But nevertheless the will, according to this author, plays an important part in this function. Certain persons who enjoy a great power of will over themselves fall asleep when they wish, no matter at what time of day or night. Napoleon was noted for his control of sleep, and his celebrated phrase is well known: "When I wish to interrupt a certain affair," he said, "I shut up its drawer and open that of another. They do not mingle with each other, and never trouble or fatigue me. If I think I wish to sleep, I close all the drawers and straightway I'm asleep." It is a familiar fact among hypnotists that sleep is suggested like any other act. This tends to show that sleep is a form of action under the control of the will, which may be influenced by our ideas. In view of the prevalence of disturbances of sleep in mental and nervous diseases this aspect of it is not without interest. In many of these cases the difficulty of inducing sleep is very great. The root of the trouble often lies in a lack of capacity on the part of the patient to learn how to become sleepy. When in consequence of fatigue the abulia is increased, we find in them also that the insomnia increases in equal proportion. Furthermore, a patient of this character cannot awaken by herself after sleep, or being only half awake does not seem to have the power to be wholly in one state or the other. This experience, in a mild form, is not an uncommon event even in normal persons. Who has not found himself in the half awake state, following a night's sleep, gently enthralled by a dreamy reverie, from which he is unable to awaken

until a motive idea as a stimulus calls the will to action.

The general abulias, which apply at the same time to both action and thought, are practically of more importance. General abulias of the motor type are of all degrees of intensity from slight hesitation of voluntary acts to extreme indecision and powerlessness. This condition cannot be explained by any form of paralysis nor can it be attributed to a fixed idea. In the milder forms such acts become painful, slow, of short duration, and are interrupted with innumerable delays. The patient takes an interminable time to dress, to sew a few stitches, or write the simplest letter. She experiences especially a great pain in coming to a decision and in beginning any new work. To succeed in doing anything at all, these patients are obliged to divide and subdivide acts which appear to others very simple, and notwithstanding the greatest deliberation they never succeed in doing anything of a complex nature.

One of the forms of general abulia is the intellectual type. Before considering this class of abulias I need first to recall to mind certain functions of the will. It should be remembered that the will has not only a motor action, as applied to muscular reaction, but it is intimately associated with the production and expression of our ideas. In fact, such authors as Wundt and Bustian regard this intellectual function of the will as the essential rôle, and that its acts are only its outer manifestations. This intellectual action of the will is commonly called attention. Its principal result is the synthesis or the combining of the lower mental processes such as sensations, precepts, memory images, etc., in such a way as to make us comprehend them. In other words, the attention acting in unison with the apperceptive tendencies of the mind gives us the "intelligence of things." It is obvious that the attention is a very important constituent of mind and it plays an equally prominent rôle in mental disease.

For many years it has been a well recognized fact that the feelings are the first element of mind to indicate a disturbance at the onset of mental breakdown. But it has not been generally known that nearly coincident with this change in the feelings we have in the volitional sphere a disturbance of the attention, as an early symptom in many cases of insanity. This is seen in the marked weakening of voluntary attention and as an immediate consequence the patient may become confused, restless, and maniacal. Again, one of the special functions of attention is its protecting influence on the higher mental mechanism. As we are constituted, myriads of sensations are constantly crowding in upon the sensorium. Now it is just here that the attention

performs its marvelous office. It stands as a screen, as it were, defending the delicate fabric of mind from this terrible assault. Were it not for its protection, no human mind would be able for long to maintain its integrity. When voluntary attention in the process of disease has become much weakened in an individual case, then not infrequently ensues the train of symptoms which we have described; the patient passes abruptly into a state of delirium.

The defects of attention were pointed out as long ago as 1834 by Leuret, by Billod in 1843, and by many recent writers. Guge, of Amsterdam, having seen analogous modifications of attention in his observations of adenoids gave them the name of *aproxexia*; a name which has been so generally well received that it has been applied to this disorder of attention when occurring in mental and nervous diseases. *Aproxexia* in mild form can often be detected by asking the patient to read a few lines from a book or newspaper. Usually the patient being told to read aloud, does so correctly, although with monotony, but when finished it is found that she understands nothing that she has read. To be sure she pronounces the words clearly and comprehends the meaning of each one separately, but the sense of the paragraph escapes her wholly.

This disorder is a particular defect of attention and is not due to trouble of sensation or perception or to the association of ideas in the ordinary sense. Some authors have attributed it to defective memory, but experiments with these cases prove that the trouble does not arise from amnesia. If *aproxexia* increases, this lack of recognition will show itself not only in reading, but in the simple perception of outward objects. This psychological phenomenon is seen in the babble and rhyming of acute maniacal states of the insane. In them it is not unusual that they fail to recognize their surroundings and mistake for others the persons whom they casually see. Apprehensive of harm they read into the unfamiliar objects about them agencies which portend them ill. Sometimes this trouble is shown, not in the perception of visual images, but in the perception of auditory sensations. As I said before, the primary symptom of mental breakdown may be shown by this trouble and as it becomes more severe the disease may pass into melancholia or maniacal excitement. When the power of attention is simply diminished a number of complex disturbances may be observed: (1) Attention is very slow and very difficult to fix; when let alone the patient gives herself up to silent or babbling reverie.

(2) When the patient is persistently urged to fix her attention the effort is attended with much suffering, the result of extreme anxiety, which frequently produces a very severe headache. The patient who fears these headaches avoids the exercise of atten-

tion as much as possible. A young man of this class said: "When I am with intimate friends I do not try often to pay attention, I just let myself go."

(3) These subjective symptoms which occur during the exercise of attention are accompanied by objective symptoms, such as involuntary motor disturbances, and in hysterical subjects the development of new anæsthesias. In the effort of attention these patients are prone to exhaust the small amount of mental force which they possess. If she is anæsthetic only on one side she becomes so on both; the sense of smell is lost and the visual field contracts. Sometimes under forced effort blindness may temporarily ensue. Not only the sensations, but also the movements are neglected. In this way grimaces, tics, jerks of arms and limbs may occur of which the person may not be aware. In the absent minded absorption of maniacal attacks in the insane the phenomena of echolalia may be frequently seen. It is a variety of subconscious act, which has its explanation in this defect of the power of attention. While speaking of this disturbance of movement, attention may be called to the involuntary movements that take place in children when learning to write or in the performance of other unfamiliar acts of a complex nature. In some susceptible persons this tendency is more than usually conspicuous, showing itself in odd mannerisms and in peculiar eccentricities of conduct. It is a striking characteristic of persons of feeble mind. Any one who has heard Blind Tom in the remarkable exhibitions of his musical talents will remember this feature in him while listening to a new score which he was expected to play at once by ear. The full vigor of his mind, being absorbed in a strong effort of attention, left the reflex actions of the lower centres unguarded by proper inhibition.

(4) This very painful attention just referred to does not usually last long in abulic patients; it oscillates, ceases, returns for a moment, and after a variable time disappears. Some patients simply turn their eyes away from their work, say they cannot continue, complaining of severe headache. With others great exhaustion comes on as they cannot do anything or feel anything for awhile. In a recent case (D. E.) after an effort to read for a short time complained of pain in his eyes, which watered, and without further warning temporary blindness supervened.

The same exhaustion may become manifest not in the senses but in the intelligence itself. Janet tells of one of his abulic patients who, becoming much interested in a scientific explanation she was making, was seized after a few moments' effort with complete *aproxexia* from which she did not recover until the next day. In this case she suddenly

stopped, fixed her eyes intently with complete immobility on the ground. She had the appearance of being deeply absorbed in thought, but she was not; she was in one of her customary crises. It is a condition of automatic reverie, supervening as a result of the total exhaustion of voluntary attention. This phenomenon in a mild form is often experienced in the normal state of health by a person who may be more or less fatigued. Suddenly the eyes become involuntarily fixed and immobile and are fastened on the ground with intense gaze as though in deep thought. But it is a deceptive appearance for the mental state is the reverse of that of absorbed attention. This automatic reverie is common at least in elderly people. The soothing influence of a cigar or pipe conduces to it; it is the state that supervenes just before one loses oneself in sleep. There are persons, especially past middle life, who, while not particularly religious or spiritually minded, find much enjoyment by attending a Quaker meeting. The obvious explanation is that under this worthy guise they find opportunity to indulge in this pleasant form of reverie; it gives also a clue to that unbecoming habit of sleeping in meeting which gives devout Friends so great concern. Another result of exhausted power of attention is to throw certain patients into violent attacks of motor excitement. Janet gives the case of a little boy who was sent to his physician from school because he had convulsions every time he was made to give strict attention to his studies. Bevan Lewis observed a case of general paresis that developed convulsions on being pressed to solve a difficult problem in mathematics.

Patients who have a moderate degree of aprosexia succeed finally in understanding, they form ideas of things but they are ill formed; they lack clearness and stability; they grasp the idea imperfectly and it soon escapes them. Hence, doubt is one of the characteristic symptoms in states of mental abulia. This fact explains the prevalence of obsessions among the nervous and insane. This doubting spirit is seen not only in the objects of sense but it also applies to memory and fancy. These patients represent to themselves the past badly and the future equally so. They doubt what they have done and what they are going to do. One doubts about the past and has false remorse; another has imaginary fears; one accuses everybody of falsifying and another accuses himself in like manner. Finally, another characteristic of aprosexia should be mentioned. It consists in an impression of novelty in which things take on a strange or unfamiliar appearance. Objects and persons take on a strange or curious aspect, which constantly excites their surprise or apprehension. This astonishment is often

the starting point of a series of questions, and when the patient is predisposed to obsessions they get easily in this way into the nervous doubting state, termed "*folie du doute*," or doubting insanity.

THE PATHOLOGY AND TREATMENT OF DIABETIC GANGRENE OF THE LOWER EXTREMITY.

By HORACE J. WHITACRE, B. S., M. D.,

CINCINNATI.

(Concluded from page 116.)

PATHOLOGICAL CONSIDERATIONS.

There is a certain uniformity in the pathological findings in the cases that have just been related, which will call for particular mention. A diabetic and a senile type of gangrene have been described by all writers on surgery for a very long time, the underlying cause of the one being considered to be the constitutional disease, of the other a senile arteriosclerosis. In 1891, Haidenhain presented a series of cases of diabetic gangrene in which he found a uniform involvement of the smaller arteries of the affected extremity, and from these findings he decided that too little attention had previously been given to the condition of the arteries in these cases, and that this arteriosclerosis was probably a most important factor in the production of diabetic as well as senile gangrene.

A majority of writers since this time have either made mention of this view expressed by Haidenhain, or have given endarteritis obliterans the leading place among ætiological factors.

My study of the nine cases reported has led me to believe that diabetic gangrene is very largely dependent upon endarteritis obliterans, and that in the absence of such arterial change this complication will not occur in diabetes mellitus.

In five of my cases the arteries were examined at different levels. In all of these cases the obliteration was complete at the ankle. In four cases the posterior tibial artery was narrowed to the diameter of an ordinary pin, by new connective tissue, and in three of these the obliteration was made complete by fresh blood clot. In two cases the obliteration was almost complete in the lower portion of the popliteal, and in five cases the popliteal artery showed such advanced change that it would have been unsafe to ligate at this point. In four cases the femoral artery was far from normal, yet in no case did secondary hæmorrhage occur.

In one case the popliteal artery alone was examined, but this artery showed a change equal to that found in those cases in which both the pos-

terior tibial and dorsalis pedis arteries were entirely obliterated at the ankle. In the case in which recovery ensued without amputation neither artery could be felt at the ankle at the time I saw the patient, but Dr. Kreidler has since informed me that pulsation returned in these arteries later. The radial and the temporal arteries gave undoubted evidence of a general arteriosclerosis, and I feel certain that this patient suffers from this disease in an advanced form.

It will be seen that all my cases of diabetic gangrene have shown an endarteritis obliterans in an advanced form, and that in all of the cases examined the main arteries were entirely obliterated at the ankle. We should expect an arterial lesion of this degree to cause gangrene certainly when unassociated with other lesions, and it seems to me that this very fact will argue strongly against any decided influence of the diabetes *per se* in producing gangrene.

I am not prepared to state that diabetes may not reduce the vitality of the tissues to this degree—indeed, Case V. would seem to favor this view—but I am prepared to state that in every one of the cases in which I have been able to examine the arteries, I have found a sufficient reason in the vessels to explain the gangrene. Haidenhain gives three conditions under which spontaneous gangrene may occur:

- (1) A deficient supply of normal blood (senile).
- (2) A normal supply of an abnormal blood (noma).
- (3) A deficient supply of an abnormal blood (diabetic).

It must certainly be granted that the diabetic condition may hasten an impending gangrene, but there seems some danger of giving this factor a more prominent place in the ætiology than it merits.

A significant fact in this connection is the extreme rarity of gangrene in young diabetics, and I am inclined to believe that the arteries were not examined in some of these cases in which this complication has been reported in such patients. It is a well established fact that endarteritis obliterans can occur in youth.

The conclusion will therefore be drawn, that the gangrene in the above reported cases was caused chiefly by the arterial lesion, and that the diabetes acted only in a contributory, and perhaps unimportant, manner.

Another observation should be made at this point. It will be noted that only one of the cases reported presented the usual symptoms of diabetes mellitus. Increase in the amount of urine,

great thirst, voracious appetite, and emaciation were regularly absent, except in this one case, and with one other exception none of these patients had felt ill previously to the appearance of the gangrene. Indeed, none of them would have been considered diabetics had the gangrene not suggested an examination of the urine.

A discussion of the ætiology and the varieties of diabetes does not fall within the scope of my paper, but I am impelled to express, at this point, a belief that the glycosuria found in the cases which have been reported represents a chemical interference with carbohydrate oxygenation, somewhat different from that found in true diabetes mellitus. Certain writers on diabetes have described a variety occurring in elderly people, which may continue for years. I do not feel competent to offer an explanation for this particular variety of glycosuria, or to classify our present knowledge on diabetes, yet it has seemed to me probable that the same arterial change which has been found in the smaller peripheral arteries of my cases is likewise present in the pancreas, and that this obliterating endarteritis might influence the nutrition of the specific cells of this organ in such manner that its internal sugar splitting secretion is either diminished or destroyed. I am unable to present histological facts in this connection, inasmuch as a post mortem examination was refused in both my fatal cases, yet I believe that such study is much needed, and that when this information is joined with the chemical facts now being announced, a "diabetes of elderly people" will have a separate classification. I am, furthermore, of the opinion that such elderly diabetics will not suffer from gangrene of the foot unless they at the same time suffer from an endarteritis obliterans. It is a point of some interest to note that the sugar disappeared from the urine of the three patients who recovered after amputation and that it did not recur on regular diet.

TREATMENT.

The treatment of diabetic gangrene of the foot will divide itself naturally into the expectant and the operative. When the gangrenous process is confined to one or more toes, the expectant line of treatment should be used, in the hope that Nature will establish a line of demarcation, that the gangrenous toe will be cast off, and that recovery will take place without operation. This termination is entirely possible, and such plan of treatment should be continued in every case until it has been demonstrated that extension to higher parts is inevitable. When the gangrenous process extends to, and involves, the dorsum or the sole of the foot, operation becomes imperative.

Two general principles dominate the expectant line of treatment:

(1) Bacterial infection.

(2) A deficient blood supply.

Bacterial infection is the serious danger in this condition. The tissues in and around the gangrenous area have long suffered a progressive diminution in their blood supply, until their vitality has reached a very low value. Indeed, the vital resistance of certain cells is so low that a contusion that would pass unnoticed in health causes death of the part. Now, inasmuch as the question of bacterial invasion of the tissues is largely one of overcoming Nature's forces of vital resistance, it becomes apparent that bacteria will find in such an area a most favorable soil. An infection in such tissues usually extends rapidly, particularly along fascial planes, and promptly causes serious constitutional symptoms.

It is clearly impossible to improve greatly the fighting power of the tissues, and we must therefore direct our efforts chiefly to the exclusion of germs. To this end, the entire foot and particularly the toes are scrubbed with soap and water. The danger of inflicting injury during this process will be much lessened if a pledget of cotton is used in washing. If there is any evidence of existing infection, or if the surrounding skin shows inflammatory reddening, a wet antiseptic dressing should be applied to the entire foot. I have employed aluminum acetate for this purpose. After twenty-four or forty-eight hours the wet dressing should be replaced by a perfectly dry dressing. Moisture is essential to germ development, and mummification of the gangrenous tissues becomes a rational step in the treatment. Indeed, it has long been an established fact that these patients do best when the gangrenous tissue is rapidly reduced to this condition. It is a common experience to see such mummified toe separate from the living tissues in a perfectly clean cut and apparently aseptic manner and to leave a satisfactory stump. In order to bring about this condition of mummification I have used large amounts of borated talcum powder on the entire region, and when there is a secretion present have ordered enough changes of dressing daily to maintain a dry condition. The dead and loosened epidermis must usually be peeled off before much progress can be made.

Next, the arterial condition must be considered. When the main arteries of the foot have become entirely obliterated, as in the cases reported, efforts to improve the circulation and the nutrition would seem to be futile. Such will probably be true in a majority of the cases, yet

there are certain measures which should be used because of the possible good, that they may do. Thus, the foot should be elevated sufficiently (six or eight inches) to obtain the effect of gravity in venous return. Again, a dilatation of the superficial vessels and a normal temperature should be maintained in the threatened tissues by enveloping the entire foot in cotton and placing hot water bottles around it.

The constitutional treatment of the diabetes should be carefully directed, for two reasons: First, it may aid in arresting the progress of the gangrene; and, second, such treatment will put the patient in better general condition to stand an amputation should this become necessary. The patient should, of course, remain continuously in bed. A strict antidiabetic diet should be prescribed, and the patient urged to drink water in large amounts. Among drugs which have been recommended for diabetes arsenic has perhaps the best claim to acceptance.

While it would seem that the recent discoveries in this disease should have given us more suggestions for treatment, it is at the same time possible that we have, in reality, a very valuable suggestion in that theory which explains the glycemia and glycosuria upon a basis of a defective oxygenation of the glucose which is thrown into the blood from the liver. If the fault is entirely or largely one of deficient oxygenation, then we must seek for those measures which stimulate this function. Arsenic is probably efficient because it acts in this way. It increases the number of red blood cells and the amount of hæmoglobin in them. Iron would seem to be a correct drug, for the same reason. Massage and exercise would probably act in the same way.

Codeine, opium, antipyrine, acetanilide, and other drugs have been used. Tyson has suggested that these drugs probably act by influencing glucose metabolism in the distal capillaries. In my recent cases I have used the following formula, the authority for which I am unable to give:

- | | | |
|-------|---------------------------------------|----------------------|
| (1) ℞ | Antipyrine | } aa grns. xv; |
| | Sodium bicarbonate | |
| | T. i. d., for three days. | |
| | Said to reduce the sugar 50 per cent. | |
| (2) ℞ | Quinine dihydrochloride..... | grns. x. |
| | S. One dose on rising, for six days. | |
| (3) ℞ | Sodii arsenitis..... | 5 c. grms.; |
| | Aquæ | 30 cc. |
| | S. One drachm, for six days. | |

Formula 1 is given but once, while formulæ 2 and 3 are given alternately for a considerable period of time.

I am not convinced, however, that this formula gives any better results than arsenic. Tyson believes that small doses of arsenic will be more efficient than large doses, and advises a dose not to exceed three drops of Fowler's solution or one thirtieth grain of arsenious acid, three times a day.

It is very doubtful whether constitutional treatment can influence the arterial condition in the type of case that I have reported. The iodides may be expected to give marked results when either the endarteritis or the diabetes is of syphilitic origin.

OPERATIVE TREATMENT.

When a gangrenous process of this type has extended to the dorsum of the foot the dangers to the patient become very great, and it is the opinion of a majority of surgeons that an amputation should be done. The questions that will interest us in this connection will be the site of amputation and the technique.

I believe that the specimens here presented leave little doubt as to the proper site for amputation. I will recall the fact that in five of my cases the popliteal artery was so seriously damaged that amputation at this level would have been unsafe. I have made two mistakes in this connection. The first was made in the first case of this kind that I treated. I thought only of the diabetic condition and amputated at the ankle. The flaps promptly sloughed, as did also the flaps of a second operation above the knee. This patient fortunately recovered. My second mistake was less pardonable. I amputated through the upper part of the leg, and in spite of seriously damaged arteries, persuaded myself that a fairly free capillary bleeding from the divided tissues meant an efficient circulation. This patient endured the first amputation well, but died as a result of the second.

I am, therefore, convinced as a result of both pathological and clinical experience, that the lower third of the femur is the site of election for amputation in these cases.

Certain points in the technique seem worthy of mention. Dr. Ochsner has advocated amputation without a tourniquet, for the reason that a diseased femoral artery may be injured by its application. Inasmuch as diabetic gangrene would seem to belong in reality to the senile type, I have followed this suggestion in operating on this type of case with satisfaction. Dr. Ochsner has further suggested that the injury to the divided tissues should be reduced to a minimum, and that no sutures should be applied. These measures recommend themselves at once as rational and essential.

The operative treatment of diabetic gangrene was formerly condemned because of its high mortality, but accurate asepsis has diminished the dangers of such operation to such a degree that amputation is now believed to be correct when the gangrenous process has extended to the dorsum of the foot.

Six cases of gangrene associated with sugar in the urine are reported above. In one case recovery ensued under the expectant plan of treatment. Amputation was done in five cases. In three of these recovery ensued, and in two death within a week after operation. As has been previously stated, one of these deaths might have been prevented by a primary amputation above the knee. My own experience seems, therefore, to be in accord with the general results, and I am encouraged to apply this treatment in all suitable cases.

The following conclusions will be drawn:

- (1) An endarteritis obliterans is the main etiological factor in so called diabetic gangrene.
- (2) In the absence of such arterial change it is believed that gangrene of the lower extremity will not often occur in diabetes.
- (3) The form of diabetes presented in this type of case varies considerably from true diabetes mellitus.
- (4) An expectant line of treatment should be followed so long as the gangrene is confined to the toes.
- (5) Amputation above the knee should be done as soon as the gangrene process involves the dorsum of the foot.

A Case of Alleged Prescribing by a Druggist.
—Counsel for Louis Berdy, who conducts a drug store on Madison Avenue, asserts that the law which gives the County Medical Society the fines imposed on persons prosecuted by its agents is unconstitutional, and says he will carry the matter to the Court of Appeals. A woman visited Berdy's store, saying she was ill, and it is alleged she was given medicine there. Berdy was held by a police court, and the case went to the Court of General Sessions. His counsel now seeks to have a ruling from a higher court. In his argument the lawyer asserted that benefits such as those conferred upon the County Medical Society have already been pronounced unconstitutional, citing the case of *Frederick Fox vs. the Mohawk and Hudson River Humane Society*, decided in February, 1901. Berdy's counsel said: "The fines are the property of the State and the special law gives them to a private corporation, for which the machinery of the courts acts as a collecting agency. The society now enjoys an unconstitutional monopoly. So far as druggists advising customers is concerned, I believe they have as much right to do so as grocers or dry goods merchants have to extol the merits of the articles they have on sale."

PRELIMINARY NOTICE OF A NEW AND SIMPLIFIED DOUBLE STAIN FOR *BACILLUS TUBERCULOSIS*.

By IRA S. WILE, M. D.,

NEW YORK,

ASSISTANT CLINICAL MICROSCOPIST, MOUNT SINAI HOSPITAL DISPENSARY.

In the clinical examination of material for tubercle bacilli, much time is spent in the technics requisite to secure total decolorization of all bacteria, excepting *Bacillus tuberculosis*.

Acting upon the theory that the retention of carbol fuchsin stain within the tubercle bacilli is due to the chemical affinity of the fatty acids, described by Koch, for the dye, it appeared feasible to me to subject the bacilli to mordant action without removing the color. It appeared reasonable to me that most other bacteria would lose their color before the tubercle bacilli would be attacked.

Deeming Labarraque's solution (sodium hypochlorite) serviceable as a mordant, I began a series of experiments which are of interest and give promise of minimizing the time necessary to stain tubercle bacilli without sacrificing definiteness or accuracy.

A thin smear of sputum, for example, is prepared according to ordinary methods, dried in the air, and fixed by passing three or more times through a flame. Carbol fuchsin is poured on the smear and heated to the steaming point (boiling is to be avoided) for about one minute. Thus far the technics is that ordinarily followed. Instead of using Gabbet's solution (sulphuric methylene blue) or decolorizing with acid alcohol and counterstaining with Bismarck brown, the smear is drained of excess of carbol fuchsin stain, washed in distilled water, and then plunged repeatedly into Labarraque's solution until the slide presents a uniform brown appearance. The slide is thoroughly washed in distilled water to remove any excess of hypochlorite solution, dried between blotting or filter papers, and examined with a $\frac{1}{12}$ immersion lens. The bacilli tuberculosis appear as red rods, solid or beaded, upon a brown field. Other bacterial forms, with the possible exception of *B. smegmæ* and *B. lepræ*, are brown in color—the red having been altered to this hue by the action of Labarraque's solution. The *B. tuberculosis* alone retains the red stain of carbol fuchsin.

The general appearance of the specimen thus stained is that of a truly double stained specimen that has been stained with carbol fuchsin, decolorized with acid alcohol, and counterstained with Bismarck brown.

By this new method of staining, there is a great saving in the time generally spent in decolorizing and counterstaining, and there is no sacrifice of diagnostic accuracy.

601 WEST ONE HUNDRED AND FORTY-EIGHTH STREET.

REMARKS ON SOME ABUSES IN THE INTRANASAL SURGERY OF TO-DAY.*

By JOHN N. MACKENZIE, M. D.,

BALTIMORE,

CLINICAL PROFESSOR OF LARYNGOLOGY AND RHINOLOGY IN THE JOHNS HOPKINS UNIVERSITY AND LARYNGOLOGIST TO THE JOHNS HOPKINS HOSPITAL.

At the meeting of the British Medical Association, held in the city of Montreal in September, 1897, during the discussion of certain ultraradical methods of intranasal operative procedure advocated by some of my English colleagues, I took occasion to protest in somewhat vigorous terms against the then indiscriminate and thoughtless employment of surgical measures within the nasal passages and the appalling and useless sacrifice of tissue and function which many of them entailed. While sounding a note of warning against certain methods which were surely destined to bring the modern surgery of this region into disrepute, I at the same time emphasized and deplored the fact that the sudden craze for operation that had developed across the seas had caught its inspiration and derived its leadership from this side of the Atlantic; and in response to the expression of surprise on the part of some of the members who had taken part in the debate, that more serious consequences had not followed in its wake, I ventured to express the opinion (speaking with all reverence) that, in the absence of other and adequate explanation of the phenomenon, the apparent infrequency of accident and fatality following the reckless use of knife and chisel was due to the operation of that mysterious force in nature which is known as the grace of God.

I do not think that the members of this association can accuse me of irresolute timidity or lack of the proper conception of the importance of radical procedures, when necessary, in the surgery of the upper air tract. In dealing with conditions that demand surgical attention I believe in the gospel of thoroughness. It is not therefore against the legitimate surgical measures employed in the nasal passages that I wish to speak, but against their abuse. The practices which I deprecated in 1897 persist, and persist in an aggravated form, to-day to the serious injury of our

* Remarks made before the American Laryngological Association, June 2, 1904.

specialty in the eyes of conservative men, and it is, therefore, against the reckless and indiscriminate performance of surgical procedures in the nasal and accessory cavities that I wish once more to enter a formal protest.

In doing so, I shall not go into an elaborate bill of particulars, but simply indicate very briefly the structures that have suffered most in the frantic rush for operation, prefacing my remarks with the statement that they are intended for a well known class of operators that are found everywhere, and are therefore not common to any community.

Burke's dictum, that you cannot indict a whole nation, is equally applicable to laryngologists the world over, and it is therefore manifestly unfair to hold the body politic of laryngology in any community responsible for the surgical antics of the fools who rush in where angels fear to tread. These latter gentry, the product of no particular land, are those who do the most injury. They clear out the nasal passages as if they were opening up a primeval forest. They saw and chisel and burrow through everything in sight, never forgetting to apply in this particular field the injunction of the Irishman at Donnybrook: "If you see a head, hit it."

Everywhere, in matters relating to intranasal surgery, there will, in the nature of things, always be honest difference of opinion. In a question of this kind it is difficult to eliminate the personal equation. From the wild enthusiast (who is by no means always the young and inexperienced) who sees an indication for operation in the slightest want of absolute symmetry or in the least departure from the perfect image as seen in diagrams and anatomical plates, to the surgical nihilist, who, either through ignorance or timidity, or both combined, hesitates to grapple with the responsibilities of the situation, each will have his say in monotonous and perpetual controversy until the end of time.

In the therapeutics of the nasal and accessory cavities the most brilliant advances and results have been achieved in the domain of surgery. Indeed, it may be laid down as a general proposition that success in the treatment of nasal disease largely depends, other things being equal, on the amount of legitimate surgery in the case. Our surgical cases are, as a rule, our most successful and therefore our most satisfactory cases.

With these preliminary observations let me proceed at once to the discussion of the subject proper of my remarks.

THE NASAL SÆPTUM.

Perhaps the most vigorously assailed of all the intranasal structures is the sæptum. No organ

in the body, not even the uterus, has been subjected to more unnecessary assault. I am speaking within the limits of the strictest conservatism when I say that fully two thirds of all operations on the sæptum (including, of course, those done by all classes of operators) are operations unnecessarily performed. The nasal sæptum is the surgical objective of every beginner in laryngology, and the "sawing out of a sæptal spur" is usually his first baptism of blood. The tyro, when uncertain what to do, seemingly takes as his rule of practice the paraphrase of an ancient law of whist, in case of doubt, smash the sæptum. What matters it if nature has decreed that asymmetry of the anterior nasal passages in the adult should be the rule? Every bulge, every irregularity of the cartilage or bone, every spur, to the amateur, is legitimate prey.

Unless the irregularity is of such a character as to cause serious obstruction and thereby cripple function, most of the spurs met with are perfectly harmless. Small spurs, especially those projecting into the inferior meatus, by acting as protective barriers against the entrance of foreign matter, may be actually productive of good to the individual. Thousands of people go through life in perfect health and comfort with large spurs of the sæptum, which, fortunately for their possessors, have remained undiscovered. Even when such deformities come in contact with opposing surfaces, the mere fact of such contact should not necessarily constitute an indication for surgical treatment. In this latter case much harm has been done by the pernicious doctrine of so called "pressure contact." According to this luminous conception, when the apex of a spur impinges upon the opposing turbinated body, there is immediately set in motion a train of symptoms (too numerous to mention), of which hypertrophy of the opposing structure and interference with "nasal drainage" are among the most conspicuous. Hypertrophy from what? Now as to deflections, dislocations, and deformities of the sæptum other than distinctly localized projections or spurs, the operation to be performed will depend upon the nature of the deformity. No single method is applicable to all cases, and it will sometimes be necessary to resort to several different procedures in individual cases before the deformity is overcome. In this particular field we find the greatest divergence of opinion as to what is best to be done. Nearly every rhinologist has his pet operation, known, or not known, by his name, some more or less ingenious and original in design, others masquerading in the guise of novelty and originality, but in reality as old in principle as the art of surgery

itself. Even a partial list of the operations performed on the sæptum would rival in length the catalogue of the ships in the Iliad or the genealogical records of Deuteronomy. Many of these, though correct and ingenious in principle, are far from satisfactory in practice. Some are unnecessarily complicated, others require a ridiculous number of instruments for their completion. In not a few instances of "successful" performances of some of them, the patient is in a much more serious plight than he was before the work on him began. When, as is not infrequently the case, long continued, disagreeable after effects follow the establishment of a "cure," I am forcibly reminded of the Irishman's definition of the grippe—that it is a disease in which you are six months sick after you have got well.

A great deal of time and trouble, in many cases, may be saved both as regards the treatment of the sæptum itself and also the after-treatment, the subsequent management of the case, in operating by a method the principle and practice of which were advocated and practised by me many years ago,¹ viz.: the removal of portions of the external wall, and notably the inferior turbinated bone of the obstructed side (or portions thereof) as a substitute in suitable cases, for operation upon the sæptum itself.

Since my original article was published, I have received several communications from various laryngologists in this country, notably from the late Dr. Jarvis, of New York, in which they have stated that the principle had not only given them great satisfaction, but had also extricated them on more than one occasion from great difficulty and embarrassment. The method is applicable in cases in which sufficient reason exists for not operating on the sæptum. Its principle may also be extended in its application to other surgical procedures within the nasal passages.

The crying need in operation on the sæptum is greater simplicity of performance. With a comparatively speaking small armamentarium, backed by a *quantum sufficit* of good, common, surgical horse sense, the surgery of the sæptum is not a complicated problem, but one which can be worked out with comparative simplicity and satisfaction. Not to multiply illustrations, what a variety of work, for example, and what delicate work can be successfully done without accident, without interruption of the duties of the individual, and without disagreeable after results by the simple means of the surgical drill in its various forms?

THE TURBINATED BONES AND BODIES.

Another wholly indefensible practice in the intranasal surgery of to-day is the wholesale removal of the turbinated bodies and bones. With some this seems to be a well recognized routine method of practice, and special apparatus have been devised for the purpose, which go under the euphonious and appropriate names of "spoke-shaves," "plows," and the like.

In dealing with obstruction or disease of any kind in the inferior meatus, the physiological fact should be forever borne in mind that, while all portions of the nasal and accessory cavities are thoroughly supplied with air in the act of respiration, the main currents do not stream through the inferior meatus, but pass in a curvilinear path through the region of the middle meatus. Considerable obstruction therefore may exist in the inferior meatus and yet respiration go on normally and with perfect ease. Hence mere obstruction or blocking of this channel, as some would have us believe, by no means negatives the idea of perfect physiological discharge of function on the part of the nasal passages. This is not only theoretically but clinically true. The fact also must not be lost sight of that, apart from its other and varied functions, the inferior turbinated body is the richest of all the intranasal structures in that curious erectile body that plays such a manifest and manifold destiny in the physiology of the organism. The removal or destruction of this important area cannot fail to be followed by deleterious consequences, and to the absolute truth of this statement the dry, secretionless, crust laden nasal passages of the victims of too much strenuous surgery often bear eloquent and silent witness.

No one questions the frequent necessity of the complete or incomplete sacrifice of the middle turbinate bone, notably in the case of accessory sinus suppuration and the radical cure of tumors of the nasal and accessory cavities, and, in occasional cases, as a substitute for operation on the sæptum. But to make it responsible for a host of woes unnumbered, and to attack it surgically from a purely theoretical standpoint, is vicious both in principle and practice. Especially preposterous is its removal for the alleged cure of the disease falsely called hay fever. In dealing with this structure, it should always be remembered that its anterior end is one of the chief buttresses against the admission of foreign matter to the air passages, the principal point at which filtration of the external air takes place. It should, therefore, not be assailed on indifferent and insufficient pretext, or sacrificed on the altar of fantastic hypothesis.

¹ On Removal of the Inferior Turbinated Body of the Obstructed Side as a Substitute for Operation on the Deflected Sæptum in Certain Cases. *New England Medical Monthly*, 1884. IV, p. 249.

THE ACCESSORY CAVITIES.

No one will dispute the fact that these cavities are often unnecessarily entered, and sometimes with harmful results. Especially is this true in the case of the antrum and frontal sinus. The sheltered position and comparative inaccessibility of the sphenoidal sinus have been a godsend to that cavity when the amateur operator has been abroad.

The cavity that has, however, suffered most at the hands of the incautious operator is the antrum. It is certainly curious, to say the least, how some operators can have seen so many cases of antral suppuration. The condition is common enough, to be sure, and examination after death reveals the fact that it is more common than would appear from purely clinical experience; but its relative frequency as compared with other diseases in the experience of some practitioners is well nigh past all understanding.

How often these cavities have been carelessly punctured or opened will never be known. Such cases do not find their way into print.

Granting that our methods of diagnosis in antral suppuration are still defective, and that it is often impossible to establish with positiveness the existence of the disease except by exploratory puncture (a procedure itself not infallible), it nevertheless behooves us even in such a simple matter, especially in acute cases, to exercise at least a little caution in such a seemingly simple matter as the puncture of the antral wall. It is a great mistake to assume that the detection of antral suppuration cannot be positively determined without exploratory puncture. In many cases there is not only presumptive, but actual, evidence of the existence of pus without the aid of needle, drill, or trephine. It is a good rule to follow to attempt in the first instance to make the diagnosis without exploratory puncture, and should the latter be necessary, as it undoubtedly is in a large proportion of cases, to be ready in the event of the discovery of pus, to proceed at once to operation, thoroughly cleansing and disinfecting the cavity after its contents have been removed. It is such an easy matter to thrust an instrument through the antral wall that it has become with some a routine practice to resort at once to that procedure in all cases of suspected antral suppuration.

While in nine hundred and ninety-nine cases out of a thousand it is perfectly harmless and safe, yet it sometimes happens (in solitary exceptional cases, it is true) that matters of grave import ensue. This happened, for example, in the dispensary of one of our large hospitals in a

case in which incautious and repeated attempts at exploration of the antrum were made. No pus was found, but the patient developed a septic empyema of that cavity, which resulted in general septicæmia and death. In this case the fault lay, doubtless, in an infected instrument and individual carelessness; but it should be remembered that such accidents are not impossible when there is not the strictest adherence to antiseptic rules.

How often has the frontal sinus been opened to find little or nothing pathological in its interior is a question that never will be answered. Even the ethmoid does not always escape. A short while ago I was consulted by a young man from the south to have his ethmoid removed for the cure of chronic bronchitis and asthma. He had consulted a leading surgeon laryngologist in one of our largest northern cities, who had informed him that his ethmoid was badly diseased in both nostrils, and proposed attacking that organ from without through the antrum. On careful examination of his case, I found a few sonorous and sibilant râles scattered throughout the chest, and a bad chronic catarrh of the nasal passages and pharynx with the profuse thick mucopurulent secretion which is characteristic of that condition. The sinuses were healthy, and, after prolonged search, I could find nothing whatever abnormal about the ethmoid. Here, then, was a case in which a well known surgeon proposed to go through a healthy antrum to remove an ethmoid which was not diseased.

If, now, we cast about for the cause or causes of this anomalous condition of affairs, we will, unfortunately, not have very far to go. Reduced to its simplest terms, the basic cause of the reckless intranasal surgery that is seen to-day is ignorance, an ignorance begotten of a lack of the proper preparatory general education which is an absolute preliminary necessity to the proper conception and practice of any special branch of medical knowledge, and the careless way in which, in many quarters, laryngology is both studied and taught.

I was once consulted by a physician who had just been appointed laryngologist and instructor in laryngology in a hospital and postgraduate school in a distant city of the Union. He came to me with the confession that, although he was supposed to be qualified for the position, he, nevertheless, was practically ignorant of what was expected of him, and that he had therefore come to me to take a special course of study which would equip him for the work before him. Out of curiosity, I asked him how much time he pro-

posed to give to special study. He said he thought he could cover the ground in six weeks. When I had recovered from the shock to my respiratory centre administered by his reply and had told him that, after graduation, I had had a two years' service in the medical and surgical wards of a large general hospital, during which time I had incidentally familiarized myself with laryngological technique, that I had subsequently spent over two years abroad in the completion of my special studies, and that finally I had spent still another year at work in other special departments of medicine before I considered myself thoroughly equipped to go before the public as a practitioner of laryngology, I never shall forget the expression of his face. He was polite enough not to give vocal expression to the emotions which stirred his soul, but he left me firmly convinced, I am sure, that any one who would require so much time for the completion of his special studies must be the most unreceptive ignoramus and the most stupendous colossus of stupidity of either ancient or modern times.

I know of another instance in which a man doing general practice was suddenly promoted to a professorship of laryngology in a large medical school who, at the time of his appointment, was actually not only unacquainted with the ordinary technique of a laryngological examination, but was also ignorant of the names and uses of the instruments employed in the surgery of the nose and throat. He attended a six or eight weeks' course in a postgraduate institution, at the expiration of which time he took his seat in the faculty of the college as clinical professor of laryngology.

These cases may be isolated and exaggerated, but the very fact of the possibility of their existence is in itself appalling and calamitous.

This brings us to the consideration of the particular type of laryngologist to whom these remarks are chiefly addressed. Let us glance for a moment at the manner of his evolution. He graduates from an institution at which he has received a fairly good, bad, or indifferent medical training. He decides at once to take up a special study. He may start out with or without any preliminary training or knowledge. The field of laryngology is alluring, and he immediately repairs to a postgraduate school or a teaching hospital; or it may be, instead of attending either, he decides to follow the practice of some operator whose chief, and often only, patent of authority consists in his having performed a certain operation a fabulous number of times. He takes a "course" of a few weeks' duration. It is always an "operative" course. Life is too short

to pass the time in such frivolous pastime as the technique of examination or the art of diagnosis; to fritter away the golden hours in the study of the commoner diseases of the climate which are in the future to constitute the bulk of his practice. His mind is set on higher things. He expects the course to be started with some such surgical procedure as extirpation of the larynx or curettement of the sphenoidal sinus. Operations such as these should constitute, in his judgment, the principia of his special education. He is surfeited with operations. At the same time, he quickly absorbs from teacher and textbook graphic descriptions of methods mapped out with mathematical precision and in seductive diagram on paper or on the blackboard, but which he learns in his later experience do not always pan out successfully on bone and cartilage. Why should he not attempt these procedures so artistic in design and, according to the accompanying narrative, so uniformly certain of the best results? Why should he restrict the theatre of his performances, when he is assured by teacher and textbook that in the bright lexicon of promise reserved for the amateur operative laryngologist there is no such word as fail? He sees difficult operations performed a score of times by a master hand, guided by special skill and the light of long experience. Why should he not proceed at once to attempt the same? All that he needs is the necessary apparatus. He is a perfect gold mine to the instrument maker. He returns home with a trunkful of all kinds of instruments for the removal or destruction of each and every portion of the respiratory tract, and with a head hot for their immediate use. He knows it all. He must establish his reputation by some spectacular surgical achievement. His motto and golden rule is the martial maxim of Danton, "*L'audace, encore l'audace, toujours de l'audace.*" He therefore does not hesitate to do a window resection of the septum for the cure of a cough, which subsequent examination may show to be due to pulmonary tuberculosis, or to remove the middle turbinated bone for any miscellaneous group of symptoms with which the patient may be affected.

In one of John Hare's exquisite little plays, that charming actor is interrupted in his character sketch by his leading artist with the observation, "I know that man. He lives in Sheffield." All of you know the man I have just described. He, too, perhaps, lives in Sheffield; but he also lives in London and in Paris and in Berlin and in New York. He also lives in Baltimore.

Another influence unfortunately on the in-

crease which has brought the practice of intranasal surgery into disrepute is the performance of the minor operations on the nasal passage by the practitioner at large, who has acquired a smattering of the subject, usually chiefly from the perusal of textbooks and attendance on a few dispensary clinics. While it goes without saying that any capable man may, by devoting special attention to the subject, acquire a sufficient amount of manual dexterity to do the ordinary operations on the nose, the fact that he does general practice, of course, is not incompatible with the possibility of their successful performance; still it is a notorious fact that such is not usually the case, and it may be safely said that nine tenths of the general workers who practise intranasal surgery are not qualified for the work, and in their disastrous attempts to go beyond their ken is found a most conspicuous illustration of the adage that a little learning is a dangerous thing. Instances of this sort may be multiplied indefinitely. One illustration will alone suffice.

There is an impression widely prevalent among mankind that almost any one can edit a newspaper or manage a hotel. Almost coextensive with this belief among the medical profession is the conviction that every general practitioner of medicine is thoroughly qualified to remove the hypertrophied lymphoid tissue in the nasal pharynx, the falsely called "adenoid" growths of childhood and later life.

In the hands of the expert, with proper instruments and technique, the operation for their removal is simple, safe, and in ordinary cases, such as the soft lymphomata usually met with, easily performed; and when completely and carefully done, there is no operation more satisfactory, not only in its immediate, but also remote results. But I need not remind you that there are abundant instances in which its removal is not so simple a matter, and often considerable skill is necessary to complete success.

These growths should be removed without complications or evil results. Personally, I have not met with any serious accident, beyond a few cases of alarming hæmorrhage, in their extirpation, a record which I attribute largely to the fact that I always use the forceps to the exclusion of all other instruments, except in cases in which the density and other peculiarities of structure call for other modes of instrumentation. But abundant evidence exists of accident, and even fatality, following attempts at their removal, and even in the practice of those of large experience. If results of serious import follow this operation by the skillful workman, how much more likely

are they to occur at the hands of the amateur who is not trained for the work? For, although a divine Providence seemingly assists at most operations of the kind, if statistics could be compiled of all the operations done by this latter class of operators and the ultimate results brought to light, the amount of damage done would appear in the form of a revelation. It is the old, old story, as in other parts of the body, of a simple surgical procedure brought into disrepute by indiscriminate and careless performance. Although the operation is in itself a simple one and in the majority of instances easily carried out, I know of few operations commonly performed in the air passages that are more easily badly done.

Let me not be misunderstood. In the narrow limits to which I have confined these remarks, it has not been my object to decry in the least degree the many excellent measures which modern ingenuity has devised for the surgical treatment of intranasal affections. No one resorts to them with more alacrity than myself when the necessity for their adoption is apparent. It is not my object to stir up strife, to impute unworthy motives to any one, or to arrogate to myself any superior wisdom in the surgical management of these diseases. Nor do I wish to shift to other shoulders all the blame. I, too, in my earlier days, have fallen by the way. Indeed, it was once facetiously said that the street in front of my office was paved with the turbinated bones of my victims.

All I desire to do is to outline as briefly as possible certain abuses which have gradually crept into the practice of our art, and which, unchecked, are sure to redound to its certain and enduring disadvantage.

The amount of reckless surgery done in the nasal passages will never be known or chronicled in the pages of medical literature, but it can be found in its abiding place in the book of the recording angel. It is high time for us to clarify the atmosphere of our ideas on this subject and for authority to call a halt. We, who are teachers of laryngology, should wake up to the responsibilities of our position and see to it that our pupils shall not leave our institutions or post-graduate schools until they are taught, on the one hand, conservatism and moderation in the surgical treatment of the simpler affections of the upper air tract, and on the other hand, thoroughness and completeness when brought into the presence of situations of graver emergency. The problem, though difficult, is not impossible of solution. The cure for the evils I have been discussing is largely educational. All are liable

to error, even the youngest of us. While impressing upon our students the absolute necessity for surgical measures in proper cases, we should at the same time make the dangers of their indiscriminate performance fully apparent. In this way only can we be reasonably sure of accomplishing the desired result. The error of first impression derived from teacher and textbook is often difficult of eradication. In the lecture room, in the clinic, in our daily walks with the student, let us make that first impression a good one.

The time has come for the higher education of the student of laryngology. I have given at length in my chairman's address at the meeting of the American Medical Association in 1901² an outline of what should constitute the study of laryngology in the university and in the higher medical education. With such a preliminary training the student is in a position to take up his life work in earnest. When the laryngologist is not made and turned out in a few weeks or months, when he approaches his special studies after a broad and liberal medical education, when he views his subject from a loftier standpoint and in the light of high ideals, then we shall see the passing of the fraternity of carpenters who have brought discredit on our specialty, and a well ordered intranasal surgery will not only take its commanding and rightful place in the estimation of the medical profession, but will also be a great and enduring blessing to the public at large.

Mortality of Michigan During December, 1904.

—The total number of deaths reported to the department of State for the month of December was 2,782, corresponding to a death rate of 13.0 per 1,000 population. This rate is higher than that for the preceding month, which was 11.6 per 1,000, but lower than the rate for December, 1903, which was 14.1 per 1,000. By ages, there were 519 deaths of infants under one year of age, 133 deaths of children aged one to four years, and 922 deaths of elderly persons aged 65 years and over. A considerable increase is shown for the rate of mortality of infants and the aged as compared with November. Important causes of death were as follows: Tuberculosis of lungs, 176; other forms of tuberculosis, 26; typhoid fever, 51; diphtheria and croup, 50; scarlet fever, 12; measles, 5; whooping cough, 10; pneumonia, 234; diarrheal diseases of infants, 42; meningitis, 35; influenza, 34; cancer, 148; accidents and violence, 181. There were two deaths from smallpox, one in Blair township, Grand Traverse county, and one in Jackson City, Jackson county.

A RECURRENT PERINEPHRITIC ABSCESS OF TWENTY-SIX YEARS' STANDING AND PRESENTING A CLINICAL PICTURE OF ADDISON'S DISEASE.*

By GEORGE A. MOLEEN, PH. G., M. D.,

DENVER.

Last year I presented before this association a case by which I aimed to show the importance of a complete examination and detail record in the study of cases, and I take pleasure in citing to you at this time one more forcibly emphasizing these points.

It is not often our good fortune to take a history of a malady extending over a quarter of a century, interposed with numerous diagnoses and prognoses and, by the "lancing of a boil," veritably annihilate the seemingly fatal symptom complex; yet such in brief is the case about to be presented.

It is not the purpose at this time to discuss the various theories regarding the pathology of Addison's disease any more than to call to mind the summary of the recorded morbid anatomical lesions of the adrenals and adjacent sympathetic structures of Rollison, as follows:

1. Fibrocaseous, due to tuberculosis.
2. Simple atrophy.
3. Chronic interstitial inflammation, leading to atrophy.
4. Malignant disease invading the capsule, including Addison's case of malignant nodule compressing the suprarenal vein.
5. Blood extravasated into the suprarenal bodies.
6. No lesion of the bodies themselves, but pressure or inflammation involving the semilunar ganglia.

Nor does it seem wise to dilate upon the possibility of unilateral pressure as a cause of this remarkable symptom complex, since three out of Addison's original eleven cases were apparently due to lesions of the gland on one side. It does, however, seem important at this time to emphasize the fact that in this case the mischief was apparently due to pressure and probably without interstitial or parenchymatous change in the gland itself, as indicated by the rapid dissipation of the characteristic symptoms and also by the remissions, to which reference will be made later.

When first seen, this patient was suffering from dysentery, and this fact, taken with the asthenia, emaciation, small rapid pulse, and apparent anemia, pointed to a "snap" diagnosis of tuberculous dysentery.

Subsequent inquiry revealed the fact that he had been told that he had an incurable "muscular wasting." The peculiar bronzing of the face and hands

* Read before the Rocky Mountain Interstate Medical Association.

was, however, something more than a cachexia. The following record was then taken:

Mr. J. A. M. Aged 45 years; born in Ohio; had been in Colorado a little over one month, came on account of his health, though not lung trouble.

Family history: Mother and father were born in Ohio; both were dead, the former as a result of rheumatism, and the latter from apoplexy, at 72 years of age. He had two sisters and three brothers living in good health. One brother dead (cause unknown); one sister died of "croup;" examination negative as to tuberculosis, tumor, or cancer, and other chronic diseases, including nervous and mental disease.

Previous history: Enjoyed good health as a child outside of the usual diseases of childhood, of which he remembers especially whooping cough. He did not have scarlet fever or diphtheria. He stated that his growth and development were those of the average child of his age, and he was quite certain that he was not noticeably fat. In 1876-'77 he had an attack of "fever and ague," and in 1878 a congestive chill (?), which, from his description, would seem to have been pleuritic (?). About 18 years ago he passed some gravel.

Present condition: About 26 years previously he noticed that his left eyelid began to droop and later the right, and that at the same time his arms and hands were becoming weak; he first noticed that he "had no grip in his hands." This weakness increased gradually, progressed very slowly, finally involving his legs, which, like the arms, became very weak, though they did not diminish in size to any great extent.

In May, 1893, while eating he suddenly became unable to swallow, which difficulty persisted until about November of the same year, when, with the slow return of this faculty, he became stronger. Previous to this attack, however, though weak, he worked, though he would frequently drop things, e. g., he could not milk, or when ploughing he would have to use both hands at the corners.

After the onset of these attacks he would become weaker and weaker for two or three months, then gradually improve, very slowly, reaching his climax in about two years. He had had three attacks (previous to the present one) about four years apart, and in the interval he would become quite strong, though his hands would never regain their proportionate strength, and he stated that in the present attack his hands are stronger than in the beginning.

He became exceedingly well two years before, and believing himself to have recovered, he was married.

The present attack began in February, 1903, as before, by a drooping of the left eyelid, followed by the right, and at the same time he noticed a "drawing sensation" in the calves of both legs; from this time he grew gradually weaker until June, 1903, when he suffered from a chill resembling a malarial attack (i. e., chill, sweat, vomiting, followed by sleep). He was in bed about twelve days, then up and around until the last of September, when while in the yard he fell as though struck on the head, and in falling struck the back of his head; he was unconscious for about five minutes. He recalled having fallen once before. He knew he was falling each time, but could not avoid it, and he thought the unconsciousness was due to the fall. While con-

siderably weaker after this he was in the main the same as before, and in October and November he seemed stronger. In November he contracted a "grippy" cold, which he stated responded unusually well to treatment.

In January, 1904, he began to complain of pain in the right side, especially in the lumbar region, accompanied by a chill and a difficulty in speech; he could but mumble on attempt to speak. He had also during this time some difficulty in swallowing. Some time later he indicated his desire for a drink, which, when brought, he found he could swallow, and later he was able to speak clearly and had done so ever since. Until a dysentery began, about May 30th, he was gradually improving. He had had several similar attacks of dysentery.

Examination, June 15, 1904: He was a man about six feet tall, well built, and showed no marked atrophies in any muscle or group of same, though they were not as firm as usual, which could be readily accounted for by disuse. There was a seeming wasting of the thenar eminences, though the adductors of the thumbs showed as much strength as the rest of the hand muscles. He showed a slight bronze tint, especially on the face and dorsal surface of the hands, and very slight over the entire body. He was anemic in appearance and the sclerotics were bluish white in color. There were no evidences of disease in either lung.

The heart was normal in size and position, the action regular, though markedly weak and rapid, and without murmur. Pulse was small, running in character and very weak. Rate of pulse, 102; temperature, 100.5 F.

The liver dullness in the mammillary line began at the right nipple and extended two inches below the rib. There was considerable tenderness in the right hypochondrium, though not as great as in the right lumbar region.

He responded to all inquiries promptly and with clear enunciation.

In walking he moved slowly on account of weakness and the pain from which he was suffering in his right side, though there was no ataxia to be seen in his gait. He stood without swaying with his eyes open or closed. Dynamometer: R. 49, L. 20 (inner register, Tiemann dynamometer). He was right handed. Reflexes: Knee jerks, R. present and also on reinforcement. L. same; ankle clonus, absent; tendo achillis, R. present. L. same, not as great as right. Deep reflexes of the forearm, R. present. L. same, and about normal, as well also the biceps, triceps, and deltoid; masseter, absent; tongue was protruded in the median line; mouth was retracted equally and he was able to whistle, though at times he stated he had been unable to do so.

Special senses: Eyes, all external ocular motion was normal and equal. Pupils were equal and responded equally to light and accommodation. Fields were apparently normal. Discs were clear in outline and normal in color; the veins were slightly larger than the arteries.

Hearing: (watch) R. 12-24, L. 1-24. Tuning fork was heard best in the left ear. Aerial conduction was almost equal to that of bone in the left ear. R. normal (i. e., Rinne positive).

Speech was unaffected. Taste was present and equal, and there was apparently no disturbance in smell.

Sensory phenomena: All forms of sensation, including tactile, pain, pressure, postural, joint, and thermic, were present and equal.

Urine: Very turbid and yellow in color when filtered; odor foul and pungent; acid in reaction; sp. gr. 1028. No albumin, sugar, or bile; microscopically, almost entirely pus with very few blood corpuscles. Cover slips stained with carbol fuchsin and methylene blue revealed no tubercle bacilli, but there were staphylococci and a few chains of streptococci. The quantity excreted in 24 hours was 48 ounces. Urea (in 24 hours) 28.8 grammes (644.3 grains). A blood count was not made and the record of blood pressure was likewise omitted.

A diagnosis of perinephritic abscess was made and he was referred to Dr. Sherman T. Brown for operation.

[NOTE.—The patient's wife, under date of December 12th, states that he is improving steadily, being able to walk a mile without fatigue, and to carry a ten quart pail of water in either hand. In her opinion his color is better (referring to the bronzing). The tubes draining the cavity are still three inches in length—they had been about nine—and are discharging freely.]

Considering the myasthenia, tachycardia, pigmentation, especially of the hands and face, though absent in the mucous membranes and sclerotics, the gastrointestinal symptoms, and the absence of persistent bulbar disturbance, one must admit the resemblance to a case of Addison's disease. The transient attacks of ptosis and aphasia, while not usually a part of such a clinical history, do occur as shown in the case cited by Phillips (1) of simple atrophy of the adrenals, verified by autopsy.

The remissions, to which reference has been made, were accounted for by the recurrence of the abscess, which at the height of each attack, in all probability, ruptured into the pelvis of the kidney and consequently drained through the bladder, a process which was in progress when examined, though the urine at the previous examinations, I am informed through the kindness of his former physician, Dr. Pickard, contained no pus when examined by himself and Dr. Church, of Chicago.

The chills mentioned as malarial in character, and the congestive chills spoken of as supposedly pleuritic, were, one or other, noted some time in each attack. These with the increased liver dulness, pyuria, and the finding, by cystoscopic examination, that this pus was coming from the right kidney only, were reasons for the diagnosis of perinephritic abscess.

At the operation, the numerous old adhesions and the extent and course of the burrowing bore testimony to its having existed a great length of time.

Since operation the improvement has been rapid, steady, and continuous, the pigmentation, however, remaining. His rapid increase in strength is remarkable, he having walked 26 squares in a forenoon two months after. He has been taking ferruginous tonics with strychnine, to which it was deemed advisable to add two grain doses of dessicated suprarenal substance.

In the study of this case it is observed that the same general symptoms are present in nearly all conditions involving the ductless glands or their sympathetic ganglia. Most noteworthy, in the present case, is its similarity to a case of asthenic bulbar paralysis or myasthenia gravis, in which, however, there is seldom, if ever, pigmentation. Hun states (2) the important positive symptoms in establishing a diagnosis to be (1) a chronic paresis, affecting muscles supplied by many motor nerves, both spinal and cranial (ocular and bulbar); (2) rapid tiring; (3) variation in the intensity of the symptoms; and (4) the electrical myasthenic reaction. Of almost equal importance are the negative symptoms: the absence (1) of fibrillation; (2) of muscular atrophy; (3) of the electrical reaction of degeneration; and (4) of sensory symptoms.

The pathological findings in this interesting symptom complex seem to have excluded the central nervous system, though changes in and about the thymus gland are becoming more constant, as is shown in Hun's case as well as in that of Weigert. A case of Oppenheim's (3), a sarcoma of the anterior mediastinum, and that of Goldfram's in which a lymphosarcoma of the upper lobe of one lung was found, are interesting, and since Weigert's work, a considerable proportion of autopsies have shown conditions similar or analogous to the conditions described by him.

Another condition, apparently closely related, is that of exophthalmic goitre, or Basedow's disease. Nine cases of myasthenia reported by Kalischer (4), Goldfram (5-6), Karplus (7), Charcot and Marinesco (8), Murri (9), Hey (10), and Finzio (11) presented symptoms of Basedow's disease more or less pronounced (exophthalmia or goitre or both).

On the relation between Addison's disease and Basedow's disease Gowers states (12) that an affection of the abdominal sympathetic, similar to the constant affection of the cervical sympathetic, would explain the pigmentation, and the occasional watery diarrhoea seems also to show that the abdominal nerves are sometimes involved.

The heart action in all conditions is seemingly increased in rate and in exophthalmic goitre the volume is increased, in myasthenia little affected, but sometimes increased, while in Addison's disease it is almost constantly lowered.

The foremost symptom, myasthenia, which in itself would presuppose an electrical myasthenic reaction as described by Golly, may under the light of future investigation prove to be an expression of disease of the ductless glands or their sympathetic communications, and with the association of the ocular, or more particularly the palpebral nerve, the character of circulatory disturbance, the presence

or degree of pigmentation, with the gastrointestinal symptoms, we may definitely localize the seat of such disturbance.

In closing, there may be added to these observations two queries: Has the languor or fatigue so frequently observed in chronic Bright's disease an explanation in the sympathetic communication of the renal plexus? And may not the asphyxia which so often closes the scene in these cases, as in the diseases under discussion, be as likely due to this association as to uræmia?

Therapeutical Notes.

Treatment of Foreign Bodies in the Ear.—According to the *Medical Press and Circular*, for December 28, 1904, these are habitually divided into two classes—live bodies and inanimate bodies. The former consist generally of fleas, grasshoppers, or earwigs, which penetrate into the ear during sleep, while others are bred in the ear, from eggs deposited by flies, and these eggs produce worms or larvæ. Inanimate bodies are as variable as those found in the nose—pearls, shoe buttons, pebbles, beans, grains of every kind, plugs of cotton wool, paper, etc. These may remain some time without causing any trouble, but generally they provoke buzzing, vertigo, nausea, vomiting, headache, and sometimes epileptiform convulsions; symptoms that resemble cerebral disease (meningitis). Children have been treated for this affection.

If the foreign bodies are angular, pointed, infected, if they are capable of becoming swelled by humidity, if they are insects or their larvæ, they provoke violent inflammation with suppuration of the external meatus. The tympanum itself soon gets inflamed and otitis of the middle ear with all its complications sets in.

The treatment of these foreign bodies should

always begin with repeated injections which, if persevered in, frequently succeed. If the body can be reached easily, a forceps or a crooked hair-pin may be able to extract it. If, on the other hand, the symptoms are grave and threatening from penetration of the tympanum, the situation renders more radical means imperative. Either extraction should be made under chloroform or an attempt will be made to enter the middle ear and remove the obstruction.

Syphilis of the Eye.—Galezowski in the *Recueil d'ophtalmologie*, for September, 1904, states that interstitial keratitis begins as an infiltration, followed by vascularization with inflammation, and, finally, a period of regression; it is common in both the inherited and acquired disease. Chorioiditis and chorioidoretinitis commence insidiously. The symptoms are cloudy vision and muscæ; photophobia is not a marked symptom. Vision may be suddenly lost for days or weeks and restored completely, but recurrence of these attacks leads to blindness. The author has had the best results from mercurial inunction. He never uses more than 30 grains daily, rubbed in for five minutes, and continued for several months. He is not in favor of subcutaneous injections, and does not use iodides.

Bornyl Valerianate.—In recent times O. Engels has used bornyl valerianate in numerous cases of neurosis of the most varied character, including that of children, and he has been able to confirm its excellent effect on which L. Hirschlaff had already reported. It is especially useful in traumatic neurosis, hysteria, neurasthenia, epilepsy, nervous disorders of the stomach, and also in gynæcological cases. It may be mentioned particularly that it stimulates the appetite, and is free from all disagreeable secondary symptoms.

Intramuscular Injections in Infantile Syphilis.—Imerwol, in *Semaine médicale*, for June 22, 1904, recommends this treatment, and points out that ingestion by the mouth is often contraindicated by gastrointestinal disturbance, also that mercurial inunction frequently causes irritative lesions of the skin in young infants. The author employs a 5 per cent. solution of sublimate, and has used this in forty cases with satisfactory results. The number of injections was from three to five.

Treatment of Sciatica.—A simple yet effective method of relieving this painful affection, says the *Medical Press and Circular*, for December 28, 1904, will be found in the following:

- | | |
|---------------------------------------------------------|------------|
| R Nitrate of strychnine..... | 2 grains; |
| Water | 3½ ounces. |
| M. A Pravaz syringe to be injected daily in the region. | |

Gonorrhœal Endometritis.—Siredey is cited in *Nouveaux remèdes*, for November 24, 1904, as recommending the use of picric acid in the proportion of 12 parts to 1,000 of water, the solution being carefully sterilized and kept so. A uterine douche tube is used.

NEW YORK, SATURDAY, JANUARY 28, 1905.

DR. OSLER'S COLLECTED ADDRESSES.

Though for many years, ever since he took up his residence in our country, there has never been a time when Dr. William Osler has failed to receive the ready homage of the American profession, still there is much in the old saying that angels chiefly show their wings as they take their departure. Dr. Osler has not yet left us, but the time is close at hand when he is to exchange the present scenes of his activities for others far distant. We are to lose his presence and his personal glow, but never shall we forget his influence for good or cease to drink in the wisdom of his teaching.

The *quadam selecta* of such a man can never fail to keep up the genial effect of his individuality, and we are glad therefore that some of his notable addresses have been collected and printed in a volume.¹ It is a handsome book of nearly 400 pages, containing eighteen addresses. If it is chiefly by indirection that these addresses deal with the actualities of medicine, the hammer of Thor does not glance in Dr. Osler's hands. There is never any ambiguity in what is said, and there is not a particle of doubt as to its application. All his teachings are wholesome, and they are all powerfully enforced.

Were this all, the book would be read indeed, but it would then be put away for occasional reference.

But the beauty of Dr. Osler's style is such that many will leave the volume at their bedside along with the ten great works that he himself recommends to the physician for daily reading. And it will not be the least among them or the one on which the most dust will collect. To be sure, it was not needed to cap our realization of what Dr. Osler has done, but it will be prized as a graceful collation of many of his best thoughts. When its gifted author has left us—not for all time, we hope—we can study its pages and fancy that we are still in his magnetic presence.

CORRELATION IN MEDICAL TEACHING.

We have often called our readers' attention to the benefit to be derived in practice from adaptation in therapeutics, whereby the devices that have been found satisfactory in some special department of medicine are applied, *mutatis mutandis*, in other fields of work. Such adaptation may be almost endless, and, if intelligently carried out, it is sure to multiply one's therapeutic resources well nigh immeasurably. A somewhat comparable plan in teaching has lately been very forcibly advocated by Dr. R. J. Terry, professor of anatomy in the Medical Department of Washington University, in an article published in the department's *Quarterly Bulletin*, Vol. iii, No. 2. Dr. Terry's article is entitled *Class Work in Practical Anatomy*.

Dr. Terry clearly points out—with special regard, of course, to the study of descriptive anatomy—how a great deal of the hard work commonly imposed on the memory may be saved by associating purely anatomical study in the way of dissection with the study of the embryology, histology, physiology, and pathology of the several regions and organs of the body as they are gone over in a well arranged course. It is easy to see the advantages of such a plan. Let us suppose, for example, that the contents of the thorax are under examination in the dissecting room. It ought to be easy to make the study of their embryological development, their microscopical structure, and their functions coincident with that of their gross anatomy and their relations to each other and to other parts. And we see no particular reason why the didactic instruction in medicine and surgery should not at the same time be concentrated on the diseases and

¹ *Equanimitas, with Other Addresses*, Philadelphia, 1904.

injuries of the heart, the pericardium, the lungs, the pleura, the great blood vessels, and the mediastinum. It is probable that much time would thus be saved, and it seems incontestable that the teaching would be far more vivid, more likely to fix the student's attention, and sure to be accurately retained in the memory for a much longer time than if such a correlation was ignored. We presume that some approach to this system of anatomical study is carried out in many of our schools at present, but we are inclined to think that it might be more closely followed to advantage.

THE PHYSICIAN AS AN INVESTOR.

II.

One of the most important questions that confront the fairly successful physician is that of how to invest his savings. Inexperienced as he is in matters of business and finance, the matter of investment is to him usually a very formidable problem. Even the occasional physician who has had a business experience or possesses a fairly good knowledge of business is likely to be in a quandary as to what to do with his savings, because of the fact that he is so preoccupied with his profession that he has little time or opportunity to seek profitable or safe investments. Whatever the cause may be, it is a trite observation that the physician has, on the average, very little wisdom or skill in the direction of finance. He is as unfortunate in the disposition of such moneys as he may accumulate as he is in the collection of his just dues.

Real estate is usually considered the most conservative of all investments. The physician who knows this general opinion is likely to invest in real estate holdings after very little study of the situation and the locality in which he invests. In my opinion, the proposition that real estate is the most conservative form of investment for individuals who are not engaged in real estate traffic is very fallacious, or at least open to serious consideration. The individual who has an accurate knowledge of real estate values in various localities and the time and talent necessary to make quick turns of his holdings is hardly a fair criterion for the guidance of the physician whose facilities for the accurate valuation, buying, and selling of real estate are confessedly meagre.

The purchase of unimproved real estate is a very hazardous undertaking for the average doctor. Property that can be bought in locations in which a speedy rise in value is to be expected is usually snapped up by professional speculators, and the outsider is rarely able to get into the market before the prospective increase in valuation has been largely discounted. The prospective increase in value having been discounted, and the profits having been taken by the men who went in "upon the ground floor," subsequent investors are usually faced with a choice between selling at a sacrifice and holding for a prolonged period for a rise in value. It is a question which of these two horns of the dilemma is the worse. A small present loss is often insignificant as compared with the immense additional cost incidental to holding unimproved property for a few years. Burdensome and often unfair and dishonest taxation, improvements, and the loss of interest on the money invested compound the cost of the property very rapidly. This increased cost of real estate holdings more than keeps pace with a fair legitimate increase in valuation. I have had the experience of holding excellent residence property for a period of ten years, and have found that, although the property had doubled in value, it had really cost more at the end of the period during which it was doubling than the increased nominal valuation. The outlay was real, a sale at the alleged increased valuation was problematic. First, catch your buyer.

In buying unimproved property, the investor would do well to purchase corners in eligible localities, and, if possible, along section lines, in the case of city property. One of the greatest dangers in the buying of vacant property is the chance of inferior improvements or buildings used for disreputable purposes being erected in the near neighborhood. Inside property adjoining corners is especially dangerous in this respect. I have had very disagreeable experiences in this direction.

If the physician desires to buy property for investment, he should by all means buy improved property, preferably that which is used or is likely to be used for business purposes. He should be very cautious in buying new buildings for rental, for the possible profits are pretty thoroughly

squeezed out by the builder in the process of sale. It is essential in buying a piece of property to study the character of the surrounding improvements and that of their occupants. It is also essential in estimating the value of property to quietly make careful inquiries as to the values of surrounding property. Having ascertained the values of the locality in general, the prospective buyer should make confidential inquiry of some reputable loan broker as to the amount of money he would be willing to lend upon the property under consideration. Figuring this as fifty per cent. of the valuation of the property, and taking into consideration the yearly rentals and expenses of the building, it is possible for the prospective investor to form a fair estimate of values.

When dealing with the real estate agent, the prospective investor should discount all statements relative to the income and expense account of the building. So far as the income is concerned, it must be remembered that leases are very often "padded;" for example, tenants are given six months' rent free in consideration of having a lease at a high rental for the succeeding year, or rebates are given monthly. Certain builders and real estate speculators make a business of this sort of thing. It is safe to add at least one third to the expense account of a building as estimated by the builder. It is also wise to discount by from twenty to thirty per cent. the estimate of gross income. This discount is justified by the "dead beats" and suddenly impoverished among the tenants and by vacancies.

The most dangerous form of investment is in residence property. This brings up the question of the physician's owning his own home. It is a noteworthy fact that many of our shrewd business men do not own their own homes, or at least do not purchase homes until well along upon the tide of success. When they do invest, they take very good care that the shrinkage of values has already occurred at the expense of the original owner. It is well known that upon one of our fashionable avenues in Chicago the man who is ambitious to own a \$100,000 residence can purchase one of this kind for about half the original cost. The proportionate shrinkage is not so great in residences of a more modest type; still it is sufficient to warn the home buyer that he had best have a care in making his

investment. It is a safe proposition that the man who builds a residence worth from \$18,000 to \$25,000 has lost twenty per cent. of its cost the day he moves into his new home. There is such a wide variation in tastes among people who can afford residences of this description that the original owner is very fortunate if he can find some one with tastes so similar to his own as to be willing to reimburse him for his outlay in the purchase of a residence.

In a general way, the physician should remember that the equities of new buildings, whether residence, apartment, or business, are tremendously swollen by the builders or speculators who submit them to him for purchase. In many instances, by a combination of a dishonest loan broker and a wily real estate speculator or builder, the alleged equity is on paper only, the loan fully covering the original cost of both land and building. The chances for shrinkage in values here, in the hands of the purchaser, are only too obvious.

To refer again to the question of the physician's owning his own home. I believe it is better, in general, for the physician to rent a piece of residence property upon a long lease for at least the first ten years of his practice, save in localities where the mere ownership of a residence counts, as in smaller cities or towns. The ownership of a home cuts very little figure with the specialist in a large city, most of whose patients know little and care less of the location of the physician's residence, and are even ignorant of the locality in which it is situated.

One of the chief objections to the early purchase of a home is that, as the family and demands of the family of the physician increase, and the tastes of his family change, the choice has to be made between discomfort and moving into more commodious quarters. The sale of the original home is nearly always made at considerable loss, and the expense of a new and more pretentious establishment is generally such as to make it a burden upon the physician. It should be remarked in passing that the physician who rents may without losing caste live in a modest dwelling. When he builds or buys his own residence, however, he feels that he is expected by his clientèle and neighbors to make a more pretentious appearance than before.

This is one of the varieties of social blackmail of which the physician is a victim.

The best form of real estate investment for the physician is in first mortgages. Great care should be taken to deal only with reliable mortgage bankers, and to carefully inspect the property upon which the mortgage rests. When the loan has been made by conservative parties, the possible shrinkage in real estate values has been already discounted, as only fifty or sixty per cent. will ever be lent by judicious investors. The steady collection of interest and the compounding of moneys thereby obtained are a very much safer and more profitable investment on the average than buying real estate outright. The bother, worry, and expense of handling property, whether improved or unimproved, and the chances of employing dishonest agents to manage the holdings, are assumed by the owner and not by the mortgagee. The latter has decidedly the best of the bargain.

Next to first mortgages, reliable bonds are the best investment. Of these the government bond is the type and the safest of all. The interest, however, on the government bonds is so small that it is a very important item save with very large investors. Good railroad and municipal bonds and, in a few instances, corporation bonds come next in order. The financial condition of the municipality or corporation issuing the bonds should be looked into very carefully before purchase is made.

So far as stocks as an investment are concerned, and despite the fact that there are stocks upon the market which are apparently sound and profitable, the next advice that I would give is that given by Artemus Ward on the question of marriage: "Don't." The small stockholder in every stock company or corporation is at the mercy of the big fellows, and those who have enjoyed basking in the smiles of the big ones in corporations will certify that those smiles are deadly for all who are not within the sacred inner circle of manipulation. There are very few large stock corporations in the United States that have not been watered to the point of financial pernicious anemia. The average man loves to be robbed. The physician has more brains than the average man in other directions and should rise above the dead level here.

G. FRANK LYDSTON.

ORGANOTHERAPY OF THE PAST.

Attention is being called in pharmaceutical circles to the changes which are taking place in the field of therapeutics, and the subject is not without interest for members of the medical profession. A writer in a recent number of the *American Druggist and Pharmaceutical Record* touches upon the mediæval uses of the substance of animal organs in medicine, and coming down to a later period mentions the rise of organotherapy and ootherapy, the great notoriety which the use of certain animal juices obtained in Brown-Séquard's day being shown to have its counterpart in the practices of the early empirics. It is but a short step from Brown-Séquard to the present day physician who uses a large number of the active substances of animal organs, the names of which it is not necessary to enumerate here. A still further development is to be found in the synthetic chemical products which are being turned out from time to time in the great German dyeworks, to which we owe so much in the production of definite chemical preparations. The subject, we think, offers an interesting field of inquiry for either the pharmacist or the physician possessed of the historical sense and the knowledge of chemistry and medicine necessary to draw right conclusions.

DEATH OF A VALUABLE CLINICAL SUBJECT.

In the death of Magdalena Gelly the students of the Viennese hospitals have lost a valuable clinical subject as well as a teacher. This woman had acquired by practice a singular control of the muscles of the pharynx. She was able to undergo prolonged laryngoscopic examinations without reaction of the vocal cords, could produce at will spasmodic contraction of the Eustachian tube, and owing to a special sensitiveness of the mucous membranes she was able to tell students when they were at fault in properly catheterizing the tube. She would even introduce foreign bodies into the respiratory passages and allow the advanced students to practise their removal. She made her living in this manner, charging two florins for each clinical session.

Fox River Valley, Wis., Medical Society.—Dr. A. C. Mailer was elected president of the Fox River Valley Medical Society to succeed Dr. J. R. Minahan, of Green Bay, on January 17th. Other officers chosen are: First vice-president, Dr. Edward Sawbridge, of Seperison, Mich.; second vice-president, Dr. W. A. Gordon, of Oshkosh; secretary and treasurer, Dr. J. S. Reeves, of Appleton.

News Items.

Society Meetings for the Coming Week:

TUESDAY, January 31st.—Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private).

WEDNESDAY, February 1st.—New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Harlem Medical Association of the City of New York; New York Genitourinary Society; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association.

THURSDAY, February 2nd.—New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medicopsychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, February 3rd.—Practitioners' Society of New York (private); Clinical Society of the New York Post-Graduate Medical School and Hospital; Manhattan Clinical Society; Baltimore Clinical Society.

SATURDAY, February 4th.—Manhattan Medical and Surgical Society, New York (private); Miller's River, Mass., Medical Society.

Change of Address.—Dr. Winfield Ayres, to The Sydenham, 616 Madison Avenue, New York.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 21, 1905:

	January 14.		January 21.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	189	6	194	4
Diphtheria and croup	307	43	360	40
Scarlet fever	281	17	289	14
Smallpox	3
Chickenpox	202	..	179	..
Tuberculosis	338	160	404	153
Erythroid fever	56	9	50	12
Cerebrospinal meningitis	26	..	30
	1,376	261	1,476	253

Dr. George H. Baker, of Long Branch, has been elected president of the Albany Medical College Alumni Association of New York city and vicinity.

National Association for the Study and Prevention of Tuberculosis.—Dr. Livingston Farrand, professor of anthropology at Columbia University, has been named as head of this association for the current year.

Brooklyn Hospital.—The following officers have been elected: President, Theodore L. Frothingham; vice-president, Henry E. Pierrepont; treasurer, Edward Merritt; secretary, Francis L. Eames.

Skene Memorial Fund.—An anonymous donor has given \$5,000 to found the Alexander J. C. Skene Memorial Fund, the income of which is to be devoted to the purchase of books, journals, etc., relating to Dr. Skene's specialties, obstetrics and gynecology.

New York Skin and Cancer Hospital.—Dr. Bulkley's usual clinical lecture at the New York Skin and Cancer Hospital will be replaced on Wednesday, February 1st, by a lecture by Dr. Boleslaw Laponski on The Treatment of Syph-

ilis, and on Wednesday, February 8th, by a lecture by Dr. Charles Mallory Williams on The Treatment of Acne.

Gift of Mrs. Roosevelt to St. John's Hospital, Long Island City.—A basket of gold wicker, four feet high and filled with flowers made of feathers and of stuffed birds and gay butterflies and bugs, has been given to St. John's Hospital, Long Island City, by Mrs. Theodore Roosevelt. The President's wife asked that it be placed on the altar of the hospital.

Physician Injured in a Hockey Game.—Dr. J. C. MacKenzie, of the Bellevue Hospital staff, was seriously injured in the hockey game between the Brooklyn Skating Club and Hockey Club of New York teams, played in St. Nicholas Rink on January 17th. The injured player was a member of the New York team and was carrying the puck toward the Brooklyn cage when in a scrimmage the handle of an opponent's stick struck and tore a gash in his right cheek near the nose. He was carried from the ice, after his wound had been temporarily dressed, and taken to the hospital.

Gouverneur Alumni Society.—A regular meeting of this society was held at the Academy of Medicine, Wednesday, January 25, 1905, at 8.15 p. m. The meeting was a "symposium" on Cerebrospinal Meningitis. The following programme had been arranged: The Pathology of Cerebrospinal Meningitis, by Dr. Harlow Brooks; A Report Upon 60 Cases of Cerebrospinal Meningitis, by Dr. Francis Huber and Dr. P. W. Monroe; Ear Complications Met With in Cerebrospinal Meningitis, by Dr. Christopher J. Colles. Discussion by Dr. Francis Huber, Dr. John Huddleston, Dr. Frederick Huber, Dr. E. Libman, Dr. R. Van Santvoord, and others. Gouverneur Hospital furnished exceptional opportunities of studying the recent epidemic of Cerebrospinal Meningitis, and the papers presented were most interesting. J. T. Joseph Bird, M. D., president; Orrin S. Wightman, M. D., secretary.

PHILADELPHIA.

Marriage.—Dr. Percy Fitzgerald McMurdo and Miss Genevieve Le Duc were married on December 11th. Dr. McMurdo is a surgeon in the United States Navy, and has just been ordered from League Island to Baltimore.

Municipal Hospital Census.—The following is the census of the Municipal Hospital for December, 1904:

	Remaining from November.	Received.	Discharged.	Remaining to January 1st.
Diphtheria	58	89	77	16
Scarlet fever	115	57	55	4
Smallpox	6	3	6	0
Other diseases	1	0	1	0

Scientific Society Meetings for the Week Ending February 4, 1905.—Tuesday, January 31st, Medicolegal Society. Wednesday, February 1st, College of Physicians. Thursday, February 2nd, Obstetrical Society, Medical Society of the Southern Dispensary. Friday, February 3rd, American Philosophical Society.

For the Benefit of the Jefferson Medical College Hospital.—The Woman's Auxiliary of Jefferson Medical College will have a Bohemian afternoon at Horticultural Hall on February 4th. A vaudeville performance will be given; tea and light lunch will be served; and the Jefferson Orchestra will furnish music.

German Hospital Trustees Meet.—The annual meeting of the trustees of the German Hospital was held January 9th. Albert Schoenhut and Otto E. Wolf were elected to fill the vacancies caused by the deaths of C. T. Wornwag and E. G. Reyenthaler. The Reverend F. Wischan was re-elected a member of the board, on which he has served for twenty-two years.

Officers of the Samaritan Hospital.—At the annual meeting of the Samaritan Hospital, held January 7th, the following officers were elected:

President, the Reverend Russell H. Conwell; vice-president, Cyrus S. Detre; treasurer, John Little; secretary, William B. Craig; trustees, the Reverend Russell H. Conwell, John O. Bowman, Cyrus S. Detre, John Hamilton, J. Edward Moore, J. Newton Peck, John R. Young, John Little, Grant C. Osbourne, William B. Craig, Samuel S. Darmon, James I. Comly, Herman G. Hutt, John A. Presper, Jr., Frank W. Hoyt; superintendent, Charles A. Gill; chief nurse, Miss Margaret J. Maloney.

New Building for the Home for Incurables.—The Philadelphia Home for Incurables opened a new ward for men suffering from cancer on January 11th. There are at present about 150 patients in the institution, which is situated at Forty-eighth Street and Woodland Avenue, twenty-one of whom have some form of malignant tumor. The new building is of brick, containing three stories and a basement. There are sixteen rooms for patients, four for nurses, a smoking room, two dining rooms, and special diet kitchens.

Deaths.—Dr. Edwin Hellyer died on January 16th, at his home, 2341 East Susquehanna Avenue. Dr. Hellyer graduated from the Long Island College Hospital in 1864. He has been prominent in the charitable organizations of that portion of Philadelphia in which he lived; he was president of the Northeastern Soup Society for ten years; he was also a member of the Thirty-first Ward Sectional School Board. He was a member of the Philadelphia County Medical Society.

Dr. Edward Howard Craven died at his home, 1442 Franklin Street, on January 19th. Dr. Craven was a graduate of the Jefferson Medical College.

Dr. Samuel J. Weaver, of Bethlehem, Pa., died on January 18th, aged 54 years, of angina pectoris.

Dr. A. G. Wortman, of Effort, Pa., died on January 18th.

Dr. B. C. Pennington died on January 1st at his home in Atlantic City, N. J. Dr. Pennington was one of the vice-presidents of the American Medical Association, and was president of the Atlantic County Medical Society.

Dr. James M. Eagleton died of heart disease at Ocala, Florida, on January 4th, aged 70 years. Dr. Eagleton was a practising physician in Phila-

delphia for many years after his graduation from the medical department of the University of Pennsylvania. He went to Ocala, Florida, only a short time ago.

Benjamin West Frazier, Sc. D., of the faculty of Lehigh University, died in South Bethlehem on January 4th. Dr. Frazier graduated from the University of Pennsylvania in 1859. He was a member of the American Philosophical Society and of the American Association for the Advancement of Science.

The Section in Ophthalmology of the College of Physicians offered the following programme at its meeting on January 17th:

Dr. William Campbell Posey: (1) Keratitis Disciformis, with the report of a case; (2) A Further Note Upon a Case of Gunshot Wound of the Orbit; Dr. Charles A. Oliver, A Study of Simultaneous Contact Color Images; Dr. H. F. Hansell, The Treatment of Infection Following the Extraction of Cataract; Dr. C. A. Veasey: (1) A Case of Papilloma of the Lacrymal Caruncle; (2) A Case of Leucosarcoma of the Chorioid; Dr. William M. Sweet, Exhibition of a Case of Double Perforation of the Sclera by a Piece of Brass; Dr. J. Norman Risley (by invitation), An Unusual Form of Opacity, Resembling Xanthelasma of the Cornea.

Jewish Medical Charities.—During December 83 patients were admitted to the Jewish Hospital.

One thousand and fourteen patients were treated at the Mathilde Adler Loeb Dispensary during December.

Nineteen patients were admitted to the Jewish Maternity Hospital, 532 Spruce Street, during December. Thirteen births occurred during the same month.

The Health of the City.—During the week ending January 14, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	82	13
Scarlet fever.....	59	1
Chickenpox.....	121	0
Diphtheria.....	81	10
Cerebrospinal meningitis.....	2	2
Measles.....	14	1
Whooping cough.....	5	0
Tuberculosis of the lungs.....	68	52
Pneumonia.....	71	84
Erysipelas.....	6	2

The total death rate for the week was 500, in an estimated population of 1,438,318, corresponding to an annual death rate of 18.08 per 1,000 population. The total infant mortality was 105; 95 under one year, and 10 between one and two years. There were 39 still births; 18 males and 21 females. The following deaths from other transmissible diseases were reported: malarial fever, 1; tuberculosis other than tuberculosis of the lungs, 10; puerperal fever, 1; diarrhoea and enteritis under two years, 17. The temperatures were rather high for the time of year. On the 12th there was a dense fog early in the morning which interfered greatly with traffic, both in the city and on the river. The fog was caused by a rather sudden rise in temperature. A number of accident cases were treated in the various hospitals in the city, which were due to falls on icy pavements.

Medical Society Programmes.—The following was the programme of the meeting of the Phila-

delphia County Medical Society, held January 25th:

Dr. John B. Roberts, Specimens Illustrating the Need of Early Intervention in Surgical Diseases of the Abdomen; Dr. H. C. Masland, A New Saw Especially Adapted for Cranial Surgery; Dr. B. C. Hirst, The Limitations and Possibilities of Electricity in the Treatment of the Diseases of Women; Dr. T. H. Weisenburg, The Toxic Changes in Brain and Spinal Cord Due to Carcinoma.

The following was the programme of the Pathological Society of Philadelphia, held January 26th:

Dr. W. M. L. Coplin, Some Improvements in the Petri-Dish-Plate-Gelatin Method of Mounting Gross Specimens; Dr. W. M. L. Coplin, Celluloid Strips and Sheets for the Orientation of Gross Preparations in Such a Way as to Facilitate the Removal of Parts for Microscopical Study and the Subsequent Identification of the Areas from Which Such Blocks of Tissue Have Been Removed; Dr. Leo Loeb, Some Recent Contributions to the Study of the Coagulation of the Blood; Dr. H. C. Wood, Jr., The Clinical Means of Increasing the Coagulability of the Blood; Dr. R. P. McReynolds, Interstitial Fibroid Complicating Pregnancy; Dr. B. M. Anspach, Fibroid Tumors as a Complication of Pregnancy; two cases.

The following was the programme of the Society of Normal and Pathological Physiology, held January 16th:

Dr. H. C. Wood, Jr., The Comparative Germicidal Action of Salts of Antiseptic Acids; Professor Edward T. Reichert, A Schematic Eye, an Instrument for the Luminous Demonstration of the Functions of the Various Parts of the Eye, of Normal and Abnormal Refraction, and of the Application of Glasses Throughout the Whole Range of Disorders of Refraction.

The following was the programme of the meeting of the University of Pennsylvania Medical Society, held January 20th, at Dr. Alfred Stengel's office, 1811 Spruce Street:

Dr. Robert N. Willson, Syphilis with Late or Absent Secondary Eruption; Dr. R. Tait McKenzie, The Renaissance of Physical Education.

The following was the programme of the section in gynecology, College of Physicians, at the meeting held January 19th:

Dr. C. C. Norris and Dr. B. M. Anspach (by invitation), Report of 56 Consecutive Ovarian Cystomata, with Special Reference to their Complications and Malignancy; Dr. E. A. Schumann (by invitation), Secondary Metastatic Implantation of Carcinoma in the Vagina; Dr. J. C. Hirst, Vaginal Atresia Complicating Labor; Dr. R. P. McReynolds, The Use and Abuse of the Uterine Curette

Philadelphia County Medical Society.—The annual business meeting of the Philadelphia County Medical Society was held on January 18th in the lower hall of the College of Physicians. The by-laws were amended so that the society may elect as many vice-presidents as there are branches and central body. This gives the society five vice-presidents at present. The following officers were elected:

President, Dr. James M. Anders; vice-presidents, Dr. M. Howard Fussell, Dr. Albert M. Eaton, Dr. Hilary M. Christian, Dr. Franklin Brady, Dr. M. B. Hartzell; secretary, Dr. William S. Wray; assistant secretary, Dr. Ross H. Skillern; treasurer, Dr. Collier L. Bower; censor, Dr. Judson Daland; district censor to the executive council of the Medical Society of the State of Pennsylvania, Dr. Albert M. Eaton; delegates and alternates to the Medical Society of the State of Pennsylvania, Dr. Roland G. Curtin, Dr. John B. Roberts, Dr. Henry Beates, Jr., Dr. F. M. Perkins, Dr. Charles P. Noble, Dr. B. F. Stahl, Dr. A. M. Eaton, Dr. Samuel L. Wolfe, Dr. M. B. Hartzell, Dr. D. O. Kercher, Dr. Franklin Brady, Dr. Thomas H. Fenton, Dr. Alfred Stengel, Dr. James M. Anders, Dr. J. Chalmers Da

Costa, Dr. William M. Welch, Dr. A. O. J. Kelly, Dr. A. G. E. Hinkle, Dr. Herman B. Allyn, Dr. George B. Dunmire, Dr. R. N. Willson, Dr. Charles H. Frazier, Dr. R. M. Goepf, Dr. James H. McKee, Dr. Richard W. Deaver, Dr. M. H. Fussell, Dr. W. H. Good, Dr. John M. Swan, Dr. C. A. E. Codman, Dr. Jay F. Schamberg, Dr. William N. Bradley, Dr. G. A. Bardsley, Dr. L. H. Bernd.

The president, Dr. Anders, on taking the chair, made the following appointments on committees: Directors for two years, Dr. W. Easterly Ashton and Dr. J. Allison Scott; publication committee for three years, Dr. Francis T. Stewart; committee on increase of membership, Dr. David Riesman for five years. The following resolution was adopted:

Whereas, The State of Pennsylvania has not, up to the present time provided adequate accommodation for the care and treatment of its tuberculous sick. And

Whereas, The plans now in projection throughout the State, even when successfully executed, will provide for but a mere fraction of the number of those who need skillful care and medical direction, both for the saving of their lives and the protection of the community. And

Whereas, Experience has shown that by properly directed open air treatment the great majority of cases of incipient tuberculosis can be permanently cured, and that a large percentage of the daily new infections can be avoided if such patients are removed from close association with others not yet infected. Be it

Resolved, That the Philadelphia County Medical Society does hereby petition the legislature of the State of Pennsylvania, (1) for the appropriation of a certain sum of money, not less than \$500,000, to be devoted to the establishment of State camps, sanatoria, hospitals, and dispensaries for the tuberculous sick of the Commonwealth of Pennsylvania; and (2) for the setting aside of portions of the State Forestry Reserve with a view to accommodating the buildings that may be deemed necessary for the care of tuberculous patients, and for their scientific study and treatment. Further, be it

Resolved, That the president of this society be authorized and instructed to appoint a committee of three from the membership of the society to cooperate with similar committees that may be appointed from other societies in urging upon the legislature the need of State aid in the suppression of tuberculosis.

The North Branch of the Philadelphia County Medical Society elected Dr. A. B. Hirsch, chairman, and Dr. T. Turner Thomas, clerk, for the ensuing year.

The West Philadelphia Branch elected Dr. Herman B. Allyn, chairman, and C. A. E. Codman, clerk, for the coming year.

GENERAL

The Buildings of the New Hampshire School for Feeble Minded Children, which were recently burned, are to be rebuilt as soon as possible.

Leflore County, Miss., Medical Society.—This society has elected the following officers for the ensuing year: President, Dr. S. A. Eggleston, of Shellmound; vice-president, Dr. J. H. Lucas, of Greenwood; secretary-treasurer, Dr. D. S. Humphreys, of Greenwood; censor, Dr. S. L. Bristor, of Greenwood.

Dr. Francis Edgerton, of Middletown, Conn., died on January 10th, aged 67 years. He was a graduate of Wesleyan University and Columbia College, and was a former president of the Connecticut Medical Society. During the civil war Dr. Edgerton was assistant surgeon of the Twenty-first Connecticut Volunteers.

The Orange Mountain, N. J., Medical Society elected these officers at the annual meeting, January 21st: President, Dr. Richard C. Newton, of Montclair; vice-president, Dr. D. E. English, of Millburn; secretary, Dr. Richard D. Freeman, of South Orange; treasurer, Dr. J. Minor Maghee, of West Orange.

Dr. Ophelia Blinn, one of the pioneer women physicians of Chicago and a graduate of the Woman's Medical College of Philadelphia, died at the County Infirmary at Dunning, Ill., last Friday, aged 60 years. She had been ill several years.

Physicians in the United States Senate.—When the term of Senator Ball, of Delaware, expires on March 3rd, the medical profession will be left with but one representative in the United States Senate, Senator Jacob H. Gallinger, of New Hampshire.

The Plattsburgh Physicians' Club, of Plattsburgh, N. Y., was recently organized to promote by frequent meetings the professional and social welfare of the medical men of that vicinity. The officers elected were: President, Dr. F. Madden; secretary, Dr. T. Avery Rogers.

New York State Hospital for the Care of Deformed and Crippled Children.—It is stated that this institution will shortly be removed from Tarrytown to the Milburn mansion on Treason Hill, West Haverstraw, Rockland County, a site that offers many advantages.

Jefferson County, N. Y., Medical Society.—The following officers have been chosen for the ensuing year: President, Dr. E. S. Willard, of Watertown; vice-president, Dr. Potter, of Mannsville; secretary, Dr. F. R. Calkins, of Watertown; treasurer, Dr. C. M. Rexford, of Watertown.

President Garfield's Physician Dead.—Dr. S. R. Beckwith, who was President Garfield's family physician at the time of his assassination, died in Atlantic City, on January 20th, aged 72 years. Before going to Atlantic City he had resided in New York, Washington, Cleveland, and Cincinnati. He leaves a son, Dr. J. T. Beckwith, surgeon to the Atlantic City Beach Guards.

Iberville Parish, La., Medical Society.—At a meeting of the Iberville Parish Medical Society the following officers were elected to serve for the ensuing year: President, Dr. A. A. Allain, of Bayou Goula; vice-president, Dr. W. E. Barker, of Plaquemine; secretary and treasurer, Dr. W. L. Grace, of Plaquemine; censors, Dr. E. J. Kearny, of Plaquemine, and Dr. Paul Landry, of Whitecastle.

Larimer County, Colo., Medical Society.—The newly elected officers of the Larimer County Medical Society are: President, Dr. P. J. McHugh; vice-president, Dr. C. M. Haviland; secretary, Dr. E. Stiver; treasurer, Dr. W. A. Kirkland. Dr. E. Stiver was appointed a delegate to the State association meeting in Denver, and Dr. J. J. Halley, Dr. Mary D. Rieckly, and Dr. J. E. Dale were named as a committee on admissions.

University of Kansas.—There has been introduced into the Kansas legislature a bill allowing the University of Kansas to give clinical instruction in medicine at the various State hospitals and also at Kansas City, where a hospital site and some \$25,000 have been given for it. We are informed by Dr. George Howard Hoxie, of Lawrence, that if this bill becomes a law, the medical

school of the university will give its scientific and didactic work at Lawrence in the regular laboratories and then send out its students in sections to take practical work in the hospitals.

Baltimore Medical and Surgical Association.—At a meeting of this association, held on January 9th, the following officers were elected: President, Dr. C. Urban Smith; first vice-president, Dr. Charles O'Donovan; second vice-president, Dr. Nathan Winslow; secretary, Dr. Lee Crutchfield; treasurer, Dr. W. B. Perry; executive committee, Dr. James M. Craighill, Dr. Arthur Hebb, and Dr. D. Streett; committee of honor, Dr. John Neff, Dr. John W. Linthicum, and Dr. John I. Pennington.

Dr. William T. Councilman, professor of pathology in the Harvard Medical School, according to the public press, disputes the findings of the Roswell Park Commission in its study of cancer, which were to the effect that cancer can be cured by a serum. According to the despatch, Dr. Councilman stands by the findings of the Harvard experts, who recently came to the conclusion that cancer is amenable only to surgical procedure.

Dr. Charles E. Putnam, of Jersey City, was painfully injured a few days ago while attempting a rescue at a fire. As he was driving by a house which was ablaze, a woman called to him that her child was in the building. The doctor sprang out of his carriage and entered the burning structure. He made his way to the second floor, but, being unable to find the child, started to return to the street. While groping through the smoke to find the stairway, Dr. Putnam missed his footing and fell the entire length of the stairs. He was badly cut about the head and received painful bruises. The child was later found at a neighbor's residence.

Typhoid Fever in Chicago.—Typhoid fever is normally a disease of rural rather than of urban populations. For many years, under the abnormal conditions of Chicago's water supply, the reverse was true of this city compared with the country surrounding it. Even so, about 20 per cent. of all the fatal cases of typhoid occurring in Chicago were found to have been contracted outside the city. This was during a period, 1894 to 1903, when the average typhoid mortality was 3.54 per 1,000 of population. Last year, 1904, the rate was only 1.93; the lowest in the records of fifty-four years. The ratio of extraurban cases must necessarily have increased and it is a matter of interest to know to what extent. This can be learned only through the cooperation of the attending physician, and to this end attention is called to the health department's circular letter and postal card, which are duly mailed to every doctor reporting a typhoid fever death. Prompt replies will be appreciated by the Registrar of Vital Statistics.

Statement of Mortality in Chicago for the Week Ending January 21, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear popu-

lations of 1,990,750 for 1905, and of 1,932,315 for 1904:

	Jan. 21, 1905	Jan. 14, 1904	Jan. 23, 1904
Total deaths, all causes.....	691	542	517
Annual death rate per 1,000.....	15.47	14.19	13.95
By sexes—			
Males.....	331	300	300
Females.....	280	242	217
By ages—			
Under 1 year.....	117	106	91
Between 1 and 5 years.....	159	99	85
Over 60 years.....	131	127	104
Important causes of death—			
Acute intestinal diseases.....	23	20	24
Apoplexy.....	19	24	13
Bright's disease.....	15	34	32
Bronchitis.....	18	24	24
Consumption.....	77	52	66
Cancer.....	19	23	18
Convulsions.....	9	16	10
Diphtheria.....	9	11	7
Heart diseases.....	37	32	47
Influenza.....	22	20	4
Measles.....	5	2	
Nervous diseases.....	20	13	29
Pneumonia.....	120	108	106
Scarlet fever.....	3	2	3
Suicide.....	13	13	8
Smallpox.....	1	1	
Typhoid fever.....	9	7	9
Violence (other than suicide).....	26	25	16
Whooping cough.....	3	4	
All other causes.....	111	111	101

A County Medical Society on Record as Against Contract Practice.—The Mercer County Medical Society of New Jersey has recently taken positive action regarding lodge and society contracts. We are indebted to Dr. D. B. Ackley, of Trenton, for a statement from which the following facts are copied: The lodge practice in Trenton, which is the capital of New Jersey, as well as the county seat of Mercer County, has existed for thirty years. During this time the lodges and societies, which furnish free medical advice to their members and their members' families for the nominal sum of one dollar per year each, have increased from two to twenty. Such practice interferes with the general work of a physician, as well as subtracting from his dignity and causing him to offend against the code of ethics. The Mercer County Medical Society appointed a committee of three to investigate the practice. The committee has secured the signatures of every physician in Trenton to an agreement not to accept contract practice in any form; to refuse to renew contracts with lodges and societies when the term for which they have already agreed shall expire; and strictly to abide by the code of ethics of the American Medical Association and by the decision of the County Medical Society in regard to such practice. The inception of the plan to abolish the practice was due to the men holding the contracts in question. This action of the Mercer County Society is a step in the right direction, and is to be recommended to the physicians in any other community in which similar abuses exist.

Medical Society of the State of New York.—The ninety-ninth annual meeting of this society will be held on January 31, February 1, and 2, 1905, in the City Hall, Albany, N. Y. Programme:

Tuesday, 9.30 a. m. Executive Session; Opening Prayer; President's Inaugural Address; Report of the Committee of Conference; Reports of Officers and Committees; Executive Business. Papers: Dermatitis Seborrhoeica and Its Relation to Alopecia, and Other Conditions, by L. Duncan Bulkley, M. D., of New York; To What Extent Are Cyclicles Necessary in Determining the Refraction of the

Eye and in the Prescribing of Lenses, by Frank Van Fleet, M. D., of New York; Rheumatism and the Eye Muscles, by Francis Valk, M. D., of New York; Loss of Vision from Disuse of the Eye (Amblyopia ex Anopsia), by D. B. St. John Roosa, M. D., of New York; The Simulation of Appendicitis by Cholelithiasis, by George C. Lempe, M. D., of Albany; Biliary Drainage in Operations on the Gall Bladder and Biliary Ducts, by Eugene A. Smith, M. D., of Buffalo; Report of a Case of Vasomotor Disturbance Caused by Exposure of Sunlight, by Samuel B. Ward, M. D., of Albany; Report of a Case of Angioneurotic Oedema, by Clayton K. Haskell, M. D., of Bath; The Status of Supra-renal Therapy, by Samuel Floersheim, M. D., of New York; Aortitis, by Thomas E. Satterthwaite, M. D., of New York.

Tuesday, 2.15 p. m. Papers: The Antitoxine Laboratory, by Herbert D. Pease, M. D., of Albany; Recognition of Incipient Pulmonary Tuberculosis, by John H. Pryor, M. D., of Ray Brook; Phosphaturia, by James Pederson, M. D., of New York.

Tuesday, 3.30 p. m. "Symposium" on Cerebrospinal Meningitis: Pathology and Bacteriology of Cerebrospinal Meningitis, by W. T. Councilman, M. D., of Boston; Symptomatology and Diagnosis, by H. L. Elsner, M. D., of Syracuse; The History of Cerebrospinal Meningitis in America, by Abraham Jacobi, M. D., of New York; The Treatment of Cerebrospinal Meningitis, by C. G. Stockton, M. D., of Buffalo; The Eye Symptoms of Cerebrospinal Meningitis, by A. E. Davis, M. D., of New York.

Tuesday, 8.30 p. m. Senate Chamber: Address by Charles Harrington, M. D., of Boston; President's Address, by Hamilton D. Wey, M. D., of Elmira.

Wednesday, 9.15 a. m. Papers: The Correction of Nasal Deformities by Subcutaneous Operation, by John O. Roe, M. D., of Rochester; The Middle Turbinate in Diseases of the Accessory Sinuses, by J. A. Stucky, M. D., of Lexington, Ky.; Inferior Turbinate Bone, Its Function, Diseases, and Treatment, by Wendell C. Phillips, M. D., of New York; Treatment of Chronic Otitis Media, with Illustrative Cases, by W. Sohler Bryant, M. D., of New York; The Family Physician, by Robert F. Bush, M. D., of Horseheads; The Various Methods of Opening the Skull for the Removal of Tumors of the Brain, by Charles H. Frazier, M. D., of Philadelphia; Railway Spine, by Edward B. Angell, M. D., of Rochester; Report of Two Cases of Gastrectomy, with Exhibition of Patients, by Willis G. MacDonald, M. D., of Albany; The Relation of Pelvic Conditions to Nervous Disorders, by A. L. Beahan, M. D., of Canandaigua.

Wednesday, 2.15 p. m. Papers: The Non-sequitur in Medicine, by H. A. Fairbairn, M. D., of Brooklyn; Poisoning by Potassium Bichromate, by Francis Eustace Fronczak, M. D., of Buffalo.

Wednesday, 3.00 p. m. Genitourinary "Symposium." John Van der Poel, M. D., of New York, chairman. The Aetiology of Hypertrophied Prostate, by L. Bolton Bangs, M. D., of New York; Some Observations on the Technics of Perineal Prostatectomy, by George R. Fowler, M. D., of Brooklyn; Personal Experiences in Prostatic Surgery During the Last Two Years, by Willy Meyer, M. D., of New York; Suprapubic Prostatectomy, by Howard Lilienthal, M. D., of New York; Prostatism, Without Prostatic Enlargement, Its Diagnosis and Treatment, by Charles H. Chetwood, M. D., of New York; by invitation: Has the Catheter a Place in the Treatment of Chronic Prostatic Hypertrophy? by Paul Thorndike, M. D., of Boston; Conservative Perineal Prostatectomy, Results of Two Years' Experience, by Hugh H. Young, M. D., of Baltimore; a paper (title to be announced), by Francis S. Watson, M. D., of Boston.

Wednesday, 7.30 p. m. President's Reception at the Hotel Ten Eyck. Annual dinner at 8.30 p. m.

Thursday, 9.30 a. m. Business Session and Reports of Committees. Papers: Concerning the Treatment of Infantile Marasmus, by Heinrich Stern, M. D., of New York; Researches on the Blood of Epileptics, by B. Onuf, M. D., and Horace L. Grasse, M. D., of Sonoma; Three Unusual Cases of Aneurysm, by William C. Krauss, M. D., of Buffalo; A Few Thoughts Regarding Our Work, by H. A. Gates, M. D., of Delhi; A Case of Extensive Carcinoma of Tongue and Neck, Presenting Points of Special Interest, by William Seaman Bainbridge, M. D., of New York; Prophylaxis in Pregnancy and Labor, by T. Avery Rogers, M. D., of Plattsburgh.

Pith of Current Literature.

PRESSE MEDICALE.

December 7, 1904.

1. The Serofatty Membrane of the Heart, By P. POIRIER.
2. Prophylaxis Against Typhoid Fever by Means of Wright's Vaccine, By L. NATTAN-LARRIER.
3. Does Conjugal Diabetes Exist? By A. MARTINET.

1. **The Serofatty Membrane of the Heart.**—Poirier objects to the classical description of the pericardium that it is the description of the pericardium of the cadaver transformed by post mortem changes. He deems several points to be erroneous and states that the errors can be verified by the examination of frozen bodies and by radioscopic examination of the living.

2. **Prophylaxis Against Typhoid Fever.**—Nattan-LARRIER describes the adoption by the British War Office of Wright's method of vaccination against typhoid fever, the relative frequency of typhoid fever in the vaccinated and unvaccinated in the British army in all parts of the world, and the relative mortality in the two classes. Professor Wright, of Netley, has recently published a work on the subject.

3. **Does Conjugal Diabetes Exist?**—The frequency with which husband and wife suffer from diabetes causes Martinet to question whether such occurrences are purely coincidental.

December 10, 1904.

1. Indications for Prostatectomy, By E. DESNOS.
2. The Progress of Vaccination, By M. LABBÉ.

1. **Indications for Prostatectomy.**—Desnos says that the presence of an enlarged prostate is not a sufficient indication for its removal, in spite of the brilliant results which have been obtained, but that surgical intervention should be confined to those cases in which there is great torture or pain and the operation is possible, necessary, and promises to be efficacious.

2. **Progress of Vaccination.**—Labbé speaks of the progressive practice of vaccination in France and its colonies, of the manner of obtaining vaccine, the choice of subjects, and, though the transmission of tuberculosis in this way is very rare, he points out the necessity of guarding against the danger.

December 14, 1904.

1. The Œsophagosalarv Reflex, By H. ROGER.
2. Cardiac Lesions and Renal Affections,

By F. BRONOWSKI.

1. **The Œsophagosalarv Reflex.**—Roger has demonstrated by experiments on dogs that the introduction of a foreign body into the Œsophagus provokes an abundant secretion of saliva and thus the presence of a reflex which he calls by the foregoing name.

2. **Cardiac Lesions and Renal Affections.**—Bronowski tabulates the great frequency of renal complications in heart lesions and concludes that the cardiac lesions, by modifying the composition

of the blood and producing stasis in the kidneys, lessen the vitality of the latter and render them more susceptible to the action of toxins, auto-toxines, and noxious germs and to the beginning of serious disease within them.

SEMAINE MEDICALE.

December 14, 1904.

A Contribution to the Study of Localization in the Hypoglossal and Facial Nerves,

By C. PARBON and J. PAPINIAN.

Study of the Hypoglossal and Facial Nerves.—Parbon and Papinian have made sections of, and studied the changes in these nerves after the tissues at their peripheral ends had been destroyed and death had been caused by cancer in the suprahyoid region. In addition they try to establish the relations which existed between these changes and the peripheral lesion.

December 21, 1904.

Pubic Osteotomy by Gigli's Method,

By Professor R. DE BOVIS.

Gigli's Method of Pubic Osteotomy.—Bovis says the idea of pubic osteotomy is ancient and refers to a saw devised for the purpose by Aitken, of Edinburgh, in 1775. Gigli's operation consists of the section of the pubic bone in the vicinity of the symphysis by means of a filiform saw, invented by Gigli, when such intervention is indicated in obstetrical cases. Bovis describes the technics and gives the histories of two successful cases of his own.

December 28, 1904.

The Dangers Attending the Use of Camphorated Naphthol in Ordinary Practice, By CAZIN and HALLION.

Dangers from Camphorated Naphthol.—After a collation of the reported cases of death and of serious intoxication from camphorated naphthol, Cazin and Hallion describe a number of experiments which they have performed on rabbits and dogs which demonstrate that in these animals at least toxic action may be produced by absorption of the drug through serous membranes, although no lesion of the blood vessels is present.

REVUE DE MEDECINE

December, 1904.

1. Is There Such a Thing as Banti's Disease?

By GILBERT and LEREBoullet.

2. Concerning the Accelerating and Retarding of the Pulse by Means of Counting in a Loud Tone of Voice, Rapidly and Slowly, By BERNHEIM.

3. Syphilitic Diseases of the Heart, By CECIKAS.

4. Concerning the Organic Origin of Certain Phobias, By HARTENBERG.

5. Multiple Spontaneous Gangrene of the Skin, By TRUFFEL.

6. A Case of Primary Cancer of the Liver, By TOLOT.

1. **Is There Such a Thing as Banti's Disease?**—Gilbert and Lereboullet answer this question, after having analyzed the evidence, by saying that there is not. The cases which have been reported under this title show once again that the spleen

is a satellite of the liver, that it is rarely the subject of disease by itself, and that when it is diseased there is usually a preexistent lesion of the liver. This is called by the authors the hepatic spleen. This causal lesion in the liver, in the biliary apparatus or in the veins, which is more or less distinct, must be detected as early as possible. Treatment should be addressed to this condition rather than to the hypertrophy of the spleen.

5. Multiple Spontaneous Gangrene of the Skin.—Truffi narrates two cases of this condition and draws the following conclusions from his consideration of them: 1. The gangrenous focus may be located in the hypodermis with or without participation of the derma and the epiderma. 2. The necrosis of the tissues is caused by a constriction of the small peripheral vessels. 3. The formation of the necrotic plaque can be prevented by the aid of revulsive therapeutic measures, or it can at least be made very superficial. 4. The keloids which result from the cicatrization of the postgangrenous ulcerations will sometimes undergo spontaneous resolution.

REVUE DE CHIRURGIE.

December, 1904.

1. Note on a Case of Fistula of the Thyroglossal Canal,
By CORNIL and SCHWARTZ.
2. Vicious Arrangement of the Ascending Colon Caused
by Descent of the Right Kidney, By ALGLAVE.
3. Operative Wounds of the Thoracic Canal in the Cer-
vical Region, By LECÈNE.
4. Perforation of the Stomach Resulting from Ulcer,
By GROSS and GROSS.
5. Cancer of the Thyroid, By DELORE.

2. Vicious Arrangement of the Ascending Colon Caused by Descent of the Right Kidney.—Alglave draws the following conclusions: 1. The first remedy for such accidents is nephropexy by which one will relieve the ascending colon which is the initial and principal seat of the accidents under consideration, on account of the faulty position which is imposed upon it by the prolapsed kidney. 2. Nephropexy will not remedy the intestinal disturbances in all cases. It will sometimes fail to overcome a fold of the colon which may be held firmly in place by epiploic adhesions. 3. If nephropexy does not suffice to relieve the fold of the colon with its adhesions, the latter must be removed and the position and calibre of the tube restored as nearly as possible to the normal. 4. In very bad cases it will be necessary to exclude the offending loop of intestine and perform transverse ileocolostomy or ileosigmoidostomy. 5. This procedure may be called for in cases in which the liver is prolapsed as well as the kidney, and in which nephropexy will not relieve the displacement of the intestine which may be caused by the liver.

3. Operative Wounds of the Thoracic Canal in the Cervical Region.—Lecène concludes as follows: 1. These wounds are not frequent, neither are they exceptionally rare. 2. There are two classes, in one of which the wound is observed in

the course of the operation which has been performed, while in the other the symptoms indicating such a wound do not appear until several days later. 3. In the first case a clear milk-like fluid is seen flowing into the wound in rhythmical jets. 4. In the second case there is a discharge of lymph or chyle from the drainage tube or from the wound. There may also be thirst, emaciation, oliguria, and general asthenia. 5. In the 22 cases collected by the author all the patients but one recovered. 6. If the wound is discovered during the operation the peripheral end of the divided tube must be tied. This will cause no particular disturbance. The suturing of the thoracic canal has been performed but once, and can only be done when the wound is incomplete. If the wound is not discovered for several days the wound should be tamponed. Reopening the wound and ligating the vessel is a difficult procedure, and one that will seldom be imperative.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

1. Contribution to the Study of Cardiac Phenomena in
Malaria, By P. GALLENGA.
2. Characteristics and Significance of the Pyloric Fossa
(To be continued), By STEPHANO FOCCA.
3. Local Anæsthesia with Adrenalin-Cocaine,
By GIUSEPPE GUALDRIN.
4. Thyroid Treatment for Ophthalmic Hemiorbita,
By P. CONSIGLIO.

1. The Heart in Malaria.—Gallenga reports three cases of malarial infection in which he observed symptoms of cardiac insufficiency which resembled closely those seen in acute endocarditis and myocarditis accompanying infectious diseases. A study of these cases convinced him that the cardiac disturbances were not merely the result of changes in the innervation of the heart, but were indications of a severe involvement of the myocardium. There is no doubt that the myocardium may be affected in severe cases of malarial infection, especially in the æstivoautumnal type. These changes are usually functional only at first, but later on they may become anatomical, and more permanent. If the proper treatment be applied to the malarial infection, however, these cases may be favorably influenced. The functional disturbances of the heart may, however, continue for a long time after the malaria has been cured, and it is common in such cases to find a weak and irregular pulse, weak cardiac sounds, cyanosis, etc. The practical conclusion is that malarial patients with cardiac complications should not merely be treated as malarial cases, but should also receive the proper treatment for their cardiac condition. They should be treated as convalescents from an endocarditis, and the proper cardiac remedies should be employed. The condition described is often taken for the effect of anæmia, but this is a mistake. Another important point is that we should avoid too large or too frequent doses of quinine in the treatment of malaria, especially when the heart is involved. Moderate doses of quinine at intervals of three hours (half a gramme hypoder-

mically, for example) are just as efficient and less dangerous than the enormous doses sometimes given.

4. **Thyreoid Extract in Ophthalmic Hemis-
crania.**—Consiglio advises the use of thyreoid ex-
tract in hemisrania. He describes a case of very
severe recurrent migraine in which he used this
method of treatment with success. The patient was
a woman aged 40 years, who since childhood had
been subject to extremely severe hemicranias, ac-
companied by injection and irritation of the con-
junctiva of the eye on the corresponding side, a
dilatation of the pupil, and blepharospasm. The
attacks of migraine in this case recurred with great
regularity about every twenty-eight days and usually
preceded the menstrual periods. The correspondence
of the menstruation and the migraine in this case
was very complete. The woman had no attacks of
migraine during pregnancy and lactation, but de-
veloped the same attacks after weaning her infant.
At the age of 36 years, her flow became irregular
and the attacks followed suit. It was then that
thyreoid treatment was thought of. The theoretical
basis for this treatment in such cases is that the at-
tacks of migraine are caused through vasomotor
changes induced by the circulation of certain toxins
in the body, which are derived from an insufficiency
in the function of the thyreoid gland, or from a
disturbance in the balance of internal secretion be-
tween that gland and the ovaries. Tablets of thy-
reoid extract were, therefore, given to this patient,
with the result that within two months, not only
was the menstrual function restored to regularity,
but the attacks of migraine totally disappeared.

ROUSSKY VRATCH.

December 11, 1904.

1. The Treatment of Tumors of the Bladder,

By LEOPOLD CASPER.

2. Hypertrophic Myosalpingitis,

By E. D. ROUSZKI.

3. The Operative Treatment of Pyloric Stenosis,

By N. E. STERNE.

1. **Tumors of the Bladder.**—Casper's article reviews the recent advances in the methods of treating tumors of the bladder with the aid of the cysto-
scope. The diagnosis is no longer difficult, but it is not yet possible with the aid of the instruments at hand to differentiate readily between the benign and the malignant tumors. Of course, the study of the case as a whole will come in here, as it always does in doubtful cases. The treatment is divided into the palliative and the radical. The palliative treatment consists of the use of narcotic drugs for the pain and tenesmus. An enema containing one gramme of antipyrine, ten or twenty drops of tincture of opium, and fifty grammes of water may be used for this purpose. The arrest of hæmorrhage is not easy, and most of the astringents which have been recommended as vesical injections are of no use. If the hæmorrhage does not stop when the patient is at perfect rest, we must treat the bladder locally. The organ is emptied and not more than one hundred c.c. of a solution of silver nitrate (1:1000 or 1:500) are injected, in order not to distend the walls unduly. The author does not recommend adrenalin solutions, and warns

against the use of gelatin solutions for the arrest of vesical hæmorrhage. A catheter à demeure, however, often stops the bleeding—always in benign tumors—because it gives rest to the bladder. The operative removal of benign tumors may be easily performed with the author's new cystoscope, which is provided with a snare that passes around the base and takes off the growth. Several sittings may be required when the growth is large. The method is not dangerous and the author reports successful removals in thirty cases. He makes the proviso, however, that the growth must be benign, and that it must be situated favorably for snaring. Many cases of benign growths have been permanently cured by this method. For malignant tumors, the only operative treatment is high cystotomy and removal of the growth, together with a portion of the bladder. This operation gives a high mortality and is not always successful if the patient lives. Some patients develop intractable fistulæ. The tumors situated at the bottom of the bladder are especially difficult to treat. In such cases palliative measures can do a great deal. The use of narcotics, among them the newer sedatives, may be employed. Heat in every form also gives relief, especially hot baths, compresses, and irrigations with hot silver nitrate solutions.

2. **Hypertrophic Salpingitis.**—Rouzscki thinks that the subject of diseases of the Falloppian tubes has not been thoroughly worked out in spite of the exhaustive investigations of Martin and others. The classification of diseases of the salpinx is not satisfactory, and but little is known concerning the condition which Rouzscki describes; namely, hypertrophic salpingitis accompanied by a growth of muscle tissue in the walls of the tubes. He reports two cases of this type and seeks to establish its characteristics. He defines myosalpingitis, on the strength of his own cases and of the observations recorded in literature, as an inflammatory condition of the salpinx characterized by an increased thickness of the muscular layers, without any enlargement in the lumen of the tube. The name hypertrophic myosalpingitis is suggested as offering a contrast with chronic hypertrophic interstitial salpingitis. The disease occurs for the most part in young women at the height of sexual life, and not in middle-aged women. Schauta thinks that this is because there is a retrograde degeneration of the muscular structures in the tubes after the climacteric, just as sometimes occurs in fibroid tumors. The right tube seems to be most frequently affected. The cause of the primary inflammation is undoubtedly microbic in character, and possibly it is gonorrhæal in most instances. The hypertrophy also is due to an increased contraction of the tubes, owing to the obstruction of the peritoneal opening or the accumulation of material within the tube. Only in one recorded case was the peritoneal opening patulous. The hypertrophy is, therefore, largely mechanical in origin. The symptoms of hypertrophic salpingitis differ in no way from those of other forms of the disease, and are accompanied by the com-

plicating conditions of endometritis, oophoritis, and peritonitis, local or general. A prominent feature is the coincidence of the attacks of pain, etc., with the menstrual periods, and the presence of pain on one side only when one tube is hypertrophic. The only treatment possible is the removal of the affected tube.

By W. NEWCOMB CARPENTER and RICHARD LIGHTBURN SUTTON.

1. See this *Journal*, Vol. LXXX, page 187.
2. See this *Journal*, Vol. LXXX, page 329.

13. **Dengue.**—Carpenter and Sutton conclude: (1) Dengue is one of the few fevers in which a leucopenia persists from the first. (2) Blood examinations are of great value in differentiating between malaria and dengue. Even though no parasites be found, a slight leucocytosis with decided increase in the percentage of large mononuclears and transitionals is indicative of the former, while a leucopenia, with a normal differential leucocytic count or varying degrees of a small mononuclear lymphocytosis and a marked eosinophilia late in the disease, is characteristic of the latter. (3) Albuminuria is seldom seen in an ordinary attack of dengue, and then only in small amounts. The exact opposite is true of yellow fever. (4) The period of convalescence in dengue is almost invariably ushered in by a pronounced small mononuclear lymphocytosis which persists for several days. (5) It is suggested that the causative agent is a small diplococcus or a delicate bipolar staining bacillus

closely resembling Pfeiffer's organism. It is probably transmitted by the respiratory tract, and its virulence is much increased by the presence of the essential meteorological factors and by overcrowding.

BOSTON MEDICAL AND SURGICAL JOURNAL.

January 10, 1905

1. The Humane Treatment of Malignant Disease from a Surgical Point of View, By JOHN C. MUNRO.
2. A Brief Consideration of Some of the Results of the Surgical Treatment of Cancer of the Stomach,
By R. H. FITZ.
3. A New Method of Performing Gastroenterostomy,
By ALFRED H. GOULD.
4. Points Pertaining to the Management of Diabetic and Non-Diabetic Glycosuria (*To be continued*),
By HEINRICH STERN.
5. The Brown Tail Moth Eruption,
By HARVEY P. TOWLE.

1. **Malignant Disease.**—Munro reports a number of apparently hopeless cases of carcinoma which were either cured or greatly benefited by surgical intervention. Two of the cured cases were suffering from benign stenosis of the pylorus. As, however, one of the patients had been refused operation at two hospitals and told to go home to die, and as the other patient had been under the best medical care for pyloric cancer and was considered beyond surgical aid, they should be classed as suffering from malignant disease, so far as the purpose of the present paper is concerned. Three facts should be emphasized: (1) Cancer at all stages is a surgical affection and the surgeon alone should decide whether the case is beyond aid or not. (2) Surgeons should be more optimistic in treating the disease. Exploratory section should be resorted to more frequently. (3) Patients should be made to understand that while the disease is ordinarily incurable, yet they will be better treated by honest physicians that promise little than by charlatans who promise much.

2. **Cancer of the Stomach.**—Fitz takes a rather pessimistic view of the surgical treatment of cancer of the stomach. He analyzes the records of 37 patients on whom operation was performed. Twenty-eight of these patients died within two months after operation, and only one was in good condition one year after operation. The author concludes: "It would appear from this experience that merely exploratory operations in advanced malignant disease involving the stomach have a considerable mortality, afford no relief and are followed by an early death. That explorations in such advanced cases followed by operations intended to relieve symptoms have a high mortality, and that in the survivors, relief is inconstant, though sometimes prolonged at least a year. It may be admitted that the surgical treatment of advanced cases of malignant disease of the stomach is humane because it sometimes gives more or less prolonged relief, and often shortens the period of suffering even if it gives no considerable relief. On the other hand, the treatment of such cases by other than sur-

gical methods often gives more or less prolonged relief and usually makes dying easy. It may be more humane to treat every case surgically, whatever its condition at the time, or to administer a lethal dose to an incurable and suffering patient. Should the choice lie between the two methods, the latter has certain advantages in its favor."

3. Gastroenterostomy.—This is Gould's fourth paper on proposed improvements in surgical technics. The ideal operation should satisfy the following requirements: (1) The pylorus should never be closed, merely to ensure the patency of the artificial opening. (2) The gastroenterostomy opening should be so constructed that it will remain open of itself. (3) An enteroenterostomy should be performed between the proximal and the distal coils of the jejunum. (4) That as much as possible of the food should be prevented from entering the stomach, without entirely cutting off the jejunal patch from the protection of the bile against the eroding effect of the gastric juice. In the proposed operation the second requirement is attained by making the opening in the stomach at right angles to the greater curvature. This gives a diamond shaped opening when the operation is completed. The fourth requirement is obtained by constructing an artificial valve in the proximal loop of the jejunum on the stomach side of the enteroenterostomy.

MEDICAL RECORD.

January 21, 1905.

1. A Contribution to the Ætiology of Malaria, and to the Analysis of Some Relations of Meteorology to Chemical Pathology, By HOMER WAKEFIELD.
2. The Use of Sulphate of Copper Alone, and in Combination with Lime, for the Destruction of Mosquito Larvæ, as a Deodorant, and as a Disinfectant, By A. H. DOTY.
2. The Subconscious Self, By J. ALLEN GILBERT.
4. Some Painful Affections of the Feet, Diagnosis and Treatment, By CHARLES OGILVY.
5. An Inflamed Appendix in an Inguinal Hernia, Simulating Strangulation, By JOSEPH E. GOLDING.

1. Malaria.—Wakefield contends that "malaria" is a syndrome more typical in symptomatology than in incidental blood changes or specific mode of infection. It is "essentially a disease of general stasis of catabolism, involving primarily blood destruction, and is, in different cases, caused by the suboxidation of humidity, vitiated atmospheres, etc., by toxicity, of many mosquito bites, by intravascular bacterial toxins, and undoubtedly, also, by direct inhalation of atmosphere heavily impregnated with decaying organic matter, which is absorbed by the blood circulating through the pulmonary alveoli." The mosquito and the plasmodium enter very little into the author's theory of the ætiology of the disease.

2. Sulphate of Copper and Lime in Sanitation.—Doty records the results of an investigation conducted for the purpose of determining the following points: (1) The use of copper alone, or in combination with lime, for the destruction of mosquito larvæ; (2) as a deodorant;

(3) as a disinfectant. (1) Sulphate of copper combined with lime is more effective as a destroyer of mosquito larvæ or as a deodorant than when used alone. Against mosquitoes the combination is effective, not on account of its toxicity, but because it rapidly removes from the water the organic matter on which the larvæ feed. This method of destroying mosquitoes is therefore of limited applicability. (2) As a deodorant the mixture is the most valuable agent we have at present. It is cheap, harmless, and easily made. It acts rapidly on both solids and liquids and its effects are permanent. (3) As a germicide the value of the combination has as yet not been sufficiently worked out. Many experiments are being conducted in various laboratories in order to settle the question, and the information will be soon available.

4. Painful Affections of the Foot.—Ogilvy discusses at some length the following affections: (1) Rheumatism of the feet may occur. The term is mostly used by the lazy or ignorant for denoting conditions that are not rheumatism. (2) Eversion. So called weak ankle. If not attended to in time is very apt to result in flat foot. (3) Flat foot. This is of three degrees: (a) Before the arch has broken down. The condition is as a rule dependent on some malformation which weakens the foot, such as eversion or pronation. The treatment of this first stage of flat foot is the treatment of the deformity. For simple eversion or pronation with a well arched foot a Thomas heel should be worn. (b) If the arch has given away we have the second degree of flat foot. For this condition a plate, which gives lateral as well as central support should be worn, such as the Whitman plate. (c) Third degree. In this type of flat foot there is marked eversion with rigidity. The foot should be overcorrected by suitable operative intervention and then put up in plaster for three weeks. After this a plate and an inside leg brace should be worn for several months. (4) Morton toe. This condition is overcome usually by supporting the anterior transverse arch of the foot. (5) Painful heel is due to a bursitis. Treatment may be by either excising the bursa or by hollowing out the heel on the side of the bursa. The condition usually occurs with a weakened longitudinal arch or with flat foot. If this be the case a foot plate should be used, a longer one than for ordinary flat foot.

AMERICAN MEDICINE

January 21, 1905.

1. Psychiatry in Its Relation to Other Sciences, By CHARLES L. DANA.
2. Subnormal Accommodation and Premature Presbyopia, By GEORGE M. GOULD.
3. Erotomania: Considerations on Its Manifestations and Pathogenesis, with the History of an Instructive Case, By J. LEONARD CORNING.
4. Occupations with Relation to Tuberculosis, By JOHN B. HUBER.
5. Is Cæsarean Section Ever Justifiable in the Management of Placenta Prævia? By RICHARD DOUGLAS.
6. Radiotherapeutic Nihilism, By GORDON G. BURDICK.
7. President Garfield at Elberon, By ANDREW H. SMITH.

1. **Psychiatry.**—Dana's remarks do not lend themselves to recapitulation. They are presented under eight heads: (1) Psychiatry and economics; (2) psychiatry and psychology; (3) psychiatry and psychotherapy; (4) psychiatry and neurology and internal medicine; (5) psychiatry, pathology, and physiological chemistry; (6) psychiatry and criminology; (7) psychiatry and forensic or legal medicine, and (8) psychiatry and anthropology.

3. **Erotomania.**—Corning reports in detail the case of a man, aged 29 years, apparently normal to puberty, but who at this period developed a longing "for a divine woman, sinless and pure." After some years he met her in a public park. His advances were not acceptable. He so persecuted the unfortunate woman that her friends had to call the matter to the attention of his family. His disposition by this time had become so difficult that he was sent away under supervision. Erotomania is not to be confounded with nymphomania or satyriasis. In the former the love is in the head, in the latter in the flesh. The author summarizes his conclusions thus: (1) Erotomania, like other manifestations of paranoia, is due to degeneration. (2) It may occur in either men or women, but is more common in the former. (3) Broadly, it is an affection of the imagination, a morbid extravagance of the ideal. (4) In its individual manifestations, it presents the characters of a love, pathological, and essentially psychic and devoid, moreover, of carnal appetite. (5) There is nearly always, though not invariably, a tendency to personification; the subject foists his ideality upon a living person, or upon an inanimate object (statue, picture). In the latter case, his apostrophes and gestures disclose the personifying propensity. (6) The delirious idea of the erotomaniac is impulsive, obsessional, irresistibly compelling. Though his intelligence may show him the consequence of yielding to his obsession, he is powerless to resist it. He should, therefore, not be held to a legal responsibility for his acts, but should be restrained. (7) Erotomania may occasionally coexist with nymphomania or some other form of sexual aberration, or with mysticism. (8) The obsession of the erotomaniac is usually for an individual of the opposite sex. (9) While erotomania may disclose itself in youth, it is really a disease of adult life, coming on after puberty, and ending not seldom in dementia.

4. **Tuberculosis.**—Huber's paper is based chiefly on statistics furnished him by Miss Brandt, of the Charity Organization Society. The author gives a table in which the tuberculosis mortality is noted for fifty-three different occupations. We quote only a few figures which represent the deaths from tuberculosis per hundred thousand living in the same occupation. Marble and stone cutters head the list with 540.5 deaths, and bankers, brokers, and officials of companies foot it with 92.1 deaths. Physicians and surgeons are fairly immune (168.8), though not to the extent of lawyers (139.9) and clergymen (123.5).

5. **Placenta Prævia.**—Douglas reports one case in which he performed Cæsarean section for placenta prævia. The woman lived. To date, twenty-four cases have been treated by this method (Deaver). Summarized: "The argument stands about in this light. The maternal mortality of placenta prævia centralis, treated obstetrically, varies from 18 per cent. to 30 per cent.; and as Radtke has shown, many who recover sustain pelvic lesions, resulting in invalidism. Against this, when the same condition is treated by Cæsarean section, the mortality is 18.75 per cent. (Deaver). The infantile mortality in placenta prævia centralis, by vaginal delivery, is 75 per cent. to 85 per cent. In properly selected cases, it is only 56 per cent. after Cæsarean section. These are the actual figures, justified by the results up to date. It is my firm conviction that the maternal mortality can be reduced below 10 per cent. We are not warranted in anticipating a reduction in the fetal mortality below 50 per cent." The author sent out the following telegram to a number of well known men: "In placenta prævia centralis; first pregnancy; child viable; compact woman; rigid cervix; free hæmorrhage; surroundings favorable; would you endorse Cæsarean section? Kindly answer." The following answers were received: "Conditions justify such action; best chances for mother and child."—Henry D. Fry. "If child living do immediate Cæsarean section, otherwise forcible delivery for mother's sake."—W. R. Pryor. "If you do Cæsarean section, put large drain of strong iodoform gauze from uterus down through cervix."—W. R. Pryor. "Yes, would do Cæsarean section in interests of both mother and child, if very difficult to use colpeurynter."—Howard A. Kelly. "I unhesitatingly advise Cæsarean section."—George H. Noble. "Cæsarean section if cervix cannot be dilated without great danger; otherwise not."—J. Whitridge Williams. "Believe Cæsarean section safest under conditions named, if patient not exsanguinated."—Charles P. Noble. "Cæsarean section offers best chance of recovery."—Charles A. L. Reed. "By all means, yes; have had a successful and easy case only lately."—Edward J. III. "Yes, if surroundings are favorable, and if you will do the work."—L. H. Dunning. "Certainly, if cervix very rigid."—Clarence J. Webster. "Not as a rule, unless cervix very rigid, hæmorrhage more than average, and version seems difficult."—B. C. Hirst. "I do not favor Cæsarean section under the circumstances stated."—E. S. Lewis.

MEDICAL NEWS.

January 21, 1905.

1. Precautions Used by the New York City Department of Health to Prevent the Spread of Contagious Disease in the Schools of the City.
By THOMAS DARLINGTON.
2. The Cystoscope as an Aid in Genitourinary Surgery.
By FOLLEN CABOT.
3. The Relation of Cholin to Epilepsy (*To be continued*),
By Dr. JULIUS DONATH.
4. Some Ocular Reflexes—(Psychoses),
By S. W. S. TOMS.

5. Report of a Case of Postdiphtheritic Paralysis,

By WILLIAM J. BUTLER.

1. **Medical Inspection of Schools.**—Darlington goes into a detailed description of the method employed in New York for the inspection of the school children by the Health Department officers. The magnitude of the task may be imagined from a few concrete figures. In 1904 the number of examinations made was 8,261,733; the number of children excluded from school, 12,289, and the number treated by the department, 515,505.

2. **The Cystoscope.**—Cabot before using the cystoscope thinks it best to prepare the patient. For a few days sounds should be passed and bladder irrigations resorted to. Usually it is best to inject, before cystoscopy, half an ounce of a one per cent. solution of cocaine into the bladder. The cystoscope is useful for detecting incysted stones, foreign bodies, or new growths within the bladder. Careful examinations in conjunction with urethral catheterization will often throw much light on the condition of the kidneys.

4. **Ocular Reflexes.**—Toms reports four cases which illustrate how abnormal conditions of the eyes are at times capable of giving rise to symptoms whose ocular origin would ordinarily remain unsuspected. The moral would seem to be that the eyes ought to be examined regularly unless the cause of illness is quite evident.

5. **Postdiphtheritic Paralysis.**—Butler's case exhibited a postdiphtheritic paralysis of unusual extent, involving the external recti of the eyes, the soft palate, the pharynx, the abductors of the larynx, the diaphragm, and peripheral nerves. Acute cardiac dilatation, with pulmonary hypostasis, and œdema; also liver stasis. The heart in diphtheria is discussed at some length.

ANNALS OF SURGERY.

15. Fracture of the Tibial Tubercle,

By WARE.

16. Abdominal Crisis Caused by Meckel's Diverticulum,

By SMITH.

17. The Use of the Segmented Ring in Gastric and Intestinal Anastomoses,

By HARRINGTON and GOULD.

1. **Bacillus Pyocyaneus Septicæmia.**—Eastman and Keene conclude: 1. There was in their case a general septicæmia. The diagnosis rested upon the bacteriological findings. There was profound intoxication with high pulse rate and usually subnormal temperature. 2. The most marked feature was nervous excitation. 3. The finding of blastomycetes in the local ulcer explained the failure of the wound to heal. The combination of the blue pus bacillus infection with blastomycetic infection was unusual. 4. The case presented a clean incised wound which healed by first intention. The wound became infected with blastomycetes primarily and with bacillus pyocyaneus secondarily. The complication is a rare one, owing to the limited distribution of the pathogenic yeasts.

2. **The Bridging of Nerve Defects.**—Powers concludes that, although correction of the evils resulting from a gap in the continuity of a nerve is a matter of great importance in a given case, it is impossible to say definitely what form of bridging should be employed. More cases, recorded later in their history, are needed. Neuroplasty and implantation are always available resources and should be preferred at present. Resection of bone may be advisable in selected cases. Transplantation of foreign grafts should be avoided. The prognosis should always be guarded, and repeated operations may be necessary.

6. Ligation of Both Common Carotid Arteries.

—Thomas considers the following points of interest in his case: 1. The presence of a malignant growth which was so situated that radical removal was impossible, but which caused such distress that relief was urgently called for. 2. The impossibility of administering a general anæsthetic and the successful and satisfactory ligation under local anæsthesia. 3. The temporary improvement which followed in spite of the advanced stage of the disease when the operation was undertaken. 4. The high division of the common carotid which was demonstrated at the time of the second operation. This point was not observed on the right side, as the common trunk only was sought.

17. The Use of the Segmented Ring in Gastric and Intestinal Anastomosis.

—Harrington and Gould conclude as follows: 1. The process of repair is as rapid after use of the segmented ring as after a plain suture. 2. The time required for the operation is less than is required for a straight intestinal suture. 3. Such objections as weight, ulceration, difficulty of passage, etc., inherent in other mechanical contrivances, are minimized by the ring. 4. The analogy between the experimental and the human observations is so close as to show the propriety of the deductions made from the animal experiments. 5. The employment of the ring in human beings is safe and satisfactory for all sutures.

16. Undescended Testicle, By ODIORNE and SIMMONS.
17. I. Hypernephroma of Kidney; II. Fibroadenoma of Inner Wall of Ileum, By WATSON.

1. On the Morphology of Carcinoma and the Parasitic Theory of Its Ætiology.—Orth has reached the following conclusions: 1. No one up to the present time has produced proof that carcinoma is of parasitic origin. 2. There is no necessity to assume a parasitic ætiology in carcinoma.

7. Birth Fracture of the Skull.—Nicoll has operated upon 23 cases and has collected the literature of the subject, drawing the following conclusions: 1. The statement that depressed green stick fracture of the skull in infants rectifies itself if left alone lacks substantiation. It is not true of traumatic green stick fracture any more than it would be true of a similar fracture in any other part of the body. In the parturition cases it may be true in those in which there is only slight indentation. In the severer cases, especially if allowed to continue for a month, such a result if it occurred at all would be slow and partial. 2. In green stick fractures which have not, when recent and soft, been remedied by Munro Kerr's method, operation is justifiable, if only for the correction of deformity. The operation is not serious; all of the author's 23 patients recovered. 3. Inversion is preferable to elevation in the freedom from risk and the perfection of the result obtained.

9. Parotiditis Following Injury or Disease of the Abdominal and Pelvic Viscera.—Dyball summarizes his paper as follows: 1. It is most probable that cœliac parotiditis is due to the action on the parotid glands of toxic substances absorbed into the blood and derived from (a) the secretions of certain organs modified by injury or disease,

(b) toxins of microbic origin absorbed from the alimentary canal, peritoneal cavity, or bladder; (c) products of deranged digestion. 2. The occurrence of parotiditis in such disease will, therefore, depend on the presence and absorption in sufficient quantity of some of these toxic agents. 3. Suppuration is not necessary to this condition, but is due to the fact that the gland when inflamed by these agencies forms a locus minoris resistentiæ and becomes secondarily infected by pyogenic organisms, which reach it by the blood stream or by Stenson's duct. The author's theory is not capable of proof at the present time, but is in accordance with our present knowledge of pathology.

14. Dermoid Cysts of the Pelvic Connective Tissue.—Germain concludes as follows: 1. Dermoid cysts of the pelvic connective tissue are of rare occurrence. 2. They occur most frequently during the child bearing period. 3. They are located most frequently above the levatores muscles, posterior to the rectum. 4. They can be cured only by radical surgical interference. 5. Their origin is to be referred to the fetal period of life.

15. The Iliac Extraperitoneal Operation for Stone in the Lower Ureter in the Male.—Fowler demonstrates that this portion of the ureter is as freely accessible by the extraperitoneal route as the upper portion. The ureter can be explored for its entire extent, stones in the lower part being dislodged upward and extracted, or removed by incision of the ureter at the point of arrest and the wound sutured. If there is a stricture in the intramural portion of the ureter the bladder may be incised and other necessary procedures carried out without a separate suprapubic incision. This operation is simple and involves little risk. The intravesical portion of the ureter is best reached by suprapubic cystotomy. Calculi in the intravesical or intramural portions of the ureter are best reached by the suprapubic intravesical route, calculi impacted in the juxtavesical and paraeschal portions should be removed by the iliac extraperitoneal route.

10. Conservatism in Pelvic Surgery, By ROBB.

11. Gunshot Wound of the Abdomen Involving the Hip Joint. Report of a Case with Remarks,

By LAIDLEY.

1. **The Limitations of Operative Interference in Cancer of the Cervix Uteri.**—Balloch draws the following conclusions from his studies:—1. The present status of operative intervention in cancer of the cervix uteri is practically useless in cases as they usually come under the notice of the surgeon. 2. In the operable cases the only procedure offering any reasonable prospect of a permanent cure is the so called radical operation by the abdominal route. 3. Vaginal hysterectomy is useless as a radical operation, but has a place as a palliative measure. 4. The upper part of the vagina is deserving of more attention, from the standpoint of recurrence than it has thus far received. 5. The most promising outlook lies in early diagnosis, combined with thorough and complete operative measures. 6. The starvation of the disease by cutting off its blood supply is a palliative measure worthy of trial, and a valuable addition to our operative technics.

3. **Streptococci in the Air of Hospital Operating Rooms and Wards During an Epidemic of Amygdalitis.**—Rosenow summarizes his paper as follows: 1. There is such a thing as "hospital air," which under certain circumstances becomes rich in pathogenic bacteria. The surgical maxim that "wound infection means contact infection" is not necessarily true, and attention should be paid to the condition of the air when much surgical work is to be done. 2. The streptococcus becomes more virulent or more numerous during an epidemic of angina from such a cause. 3. Since the streptococcus is more virulent during an attack of amygdalitis, operators, assistants, and nurses suffering with this disease should be isolated. 4. The operator, assistant, and all who handle surgical materials before and during an operation should wear a proper mouth covering. All sterile surgical material should be exposed to the air as little as possible. 5. Operating rooms should be frequently fumigated with an efficient disinfectant.

4. **Movable Kidney.**—Sprigg draws the following deductions upon this subject: 1. The relief obtained from bandaging in any case of movable kidney will depend on the presence and the degree of associated enteroptosis. 2. Fixation of the kidney in as nearly normal a position as possible is the correct method of surgical treatment. 3. In all cases in which relief of the symptoms cannot be obtained from bandages or corsets nephropexy should be performed.

7. **Infantile Intestinal Diverticula.**—Hyde concludes: 1. The diverticulum ilei is more frequently found as a blind pouch attached or unattached to the interior abdominal wall or mesentery. Rarely it establishes open communication between the ileum and the external surface at the umbilicus. 2. It occurs more frequently in males. 3. The accoucheur should always examine the cord before and after separation and so tie it as not to include any portion of intestine which might be protruding. 4. When the fistulous exit indicates the presence of a diverticulum the safest treatment is a radical operation at the earliest possible moment.

January 7, 1905.

1. **Recurrent Effusion Into the Knee Joint After Injury,**
Based on a Series of 750 Cases,
By SIR W. H. BENNETT.
2. **A Simple Method of Separating and Collecting the Urine, Which Is Secreted by Each of the Two Kidneys,**
By W. B. CLARKE.
3. **On the Pathology and Treatment of the Hernia of Children and Their Relation to Conditions in the Adult,**
By R. H. RUSSELL.
4. **The Influence of Rainy Winds on Phthisis,**
By W. GORDON.
5. **The Cultivation of Trypanosoma Out of the Leishman-Donovan Body Upon the Method of Captain L. Rogers,**
By G. C. CHATTERJEE.
6. **Child Study and the Treatment of Paralysis in Children,**
By A. A. MUMFORD.
7. **Diet in Chronic Diseases,**
By J. HADDON.

1. **Recurrent Knee Joint Effusion.**—Bennett's paper is based upon 750 cases of the above affection, in which the effusion was recurrent either spontaneously or after another injury, usually very slight. In all the cases an interval had elapsed during which the joint was apparently entirely independent of any constitutional conditions. Of these, in 428 the symptoms of internal derangement were very precise. The proportion of male to female cases was as sixteen to one. Eighty cases were treated by operation—removal of pedunculated bodies, and of internal and external semilunar cartilages. From his experience the author concludes that when the usual methods of treatment have failed to effect a cure, exploratory operation is indicated. Further, that extensive displacement of one or even both semilunar cartilages may take place without the recurrence of any of the symptoms which are commonly regarded as characteristic of the lesion. The cases in which the displacement is greatest give rise to the fewest symptoms. Constitutional conditions seemed to play a part in 241 cases. Osteoarthritis was present in 107 cases. Radiant heat baths, massage, and electric vibration were the only modes of treatment which seemed to have more than a palliative effect. In 23 recent cases they appeared to effect an actual cure. Rheumatism and gout were present in 30 cases, and as a rule the usual constitutional measures gave relief. In 42 syphilitic cases no permanent benefit was obtained until a course of antisyphilitic treatment was adopted. In 28 cases there was a history of gonorrhoea, 17 of the patients having obvious gleet. Operations were performed to relieve tension, aspiration effecting the purpose as perfectly as incision. An interesting class of cases were the ones where there was a history of malaria, mostly contracted in South Africa. Eighteen such cases were seen. There were thirteen instances of quiet effusion in young people, a condition to which the author has previously called attention.

2. **Separation of Urine.**—Clarke calls attention to the great value and efficiency of the Luys separator, for separating and collecting the urine which is secreted from each of the two kidneys.

It is simple to introduce, does not require an anæsthetic and for the time being converts the bladder into two halves by means of a vertical sæp-tum, raised into place after the instrument has been introduced. Each half of the base of the bladder receives the urine from the corresponding ureter and delivers it by a separate channel. Thus the urine can be watched flowing from each kidney. The author cites a number of cases which illustrate what an aid to diagnosis the instrument has been.

4. Wind and Phthisis.—Gordon has previously shown that in Devonshire the mortality from phthisis is much greater in those districts which are exposed to the strong prevalent rainy winds than in those which are sheltered from them, and that winds are injurious to phthisical patients. In this paper he endeavors to show: 1. That in many countries exposure to strong rainy winds is accompanied by increased phthisis mortality. 2. That in the most successful health resorts for phthisis strong rainy winds are not prevalent. 3. That the influence of these rainy winds on the prevalence of phthisis is more powerful than that of any other influence, except marked difference of race and, in some countries, of occupation.

5. Trypanosomes.—Chatterjee, following the method of Rogers, has succeeded in cultivating trypanosoma from the Leishman-Donovan bodies. The blood containing the bodies was obtained by spleen puncture, and five c.c. of blood were mixed in a test tube with one c.c. of sterile five per cent. citrate of sodium solution. On the first day three or four Leishman-Donovan bodies could be seen in every field of a stained specimen. On the second day 200 to 500 bodies could be seen in a field: they were larger, the micronucleus was larger, and the cell contents were more granular. On the third day elongated bodies with flagella could be seen, and fully developed trypanosoma-like bodies. In hanging drop specimens motile elongated flagellate bodies could be seen, but the movement was much slower than that of an ordinary trypanosome. The parasite seems to differ from the ordinary trypanosoma in the following respects: (1) the position of the micronucleus at the anterior end of the body of the parasites; (2) the long, thick, anterior flagellum; (3) the absence of (or, if present, rudimentary) undulating membrane; and (4) the rudimentary posterior flagellum. As far as these points go, they seem rather to be allied to the class of trypanopsis described by Keysseltz.

7. A Case of Cutaneous Anthrax Successfully Treated by Scelavo's Serum,

By C. B. LOCKWOOD and F. W. ANDREWES.

8. Value of Nitroglycerin in the Practice of Surgery,

By F. ELVY.

1. Tabes.—Gowers states that pain is a frequent symptom of tabes—far more common than ataxy and beginning earlier in the course of the disease. The symptoms of tabes are probably due to a chemical toxine, which results from syphilis. A ferment is produced which slightly influences the albuminous bodies in the process of their production, yet enough to convert them into nerve poison instead of a food. This toxine influences chiefly the elements of the lower sensory spinal neuron. The pains of tabes are an early and distressing symptom: they are often thought to be rheumatic. They may be classified as follows: A. Brief momentary pains, succeeding each other after a short interval in the same place. (1) Superficial. These seem to be on or just under the surface, and are usually felt at one spot. They are most common on the limbs, especially the lower legs and feet. They are extremely brief but recurring: from their character arose the name "lightning pains." They have the remarkable effect of leaving the skin *very* tender, and thus may occur where sensibility to pain has been lost. 2. Deep seated. These pains cannot, as a rule, be definitely located, but sometimes are referred to the joints. They have the same characters as the superficial pains, but are not so momentary, usually lasting several seconds. They are chiefly felt in the limbs, and they are not followed by hyperæsthesia. B. Prolonged pains, lasting for days or hours in the same place. They are most common in the trunk, and are usually deep seated, an exception being the girdle pain or sensation. They sometimes closely simulate sciatic neuritis. A common variety is a sense of distressing tension on the tendons or muscles. Very intense pains have often a burning character. There is very seldom at any exciting cause. Widely diffused distressing sensations also occur, such as numbness, tingling, swelling, etc. In one form of the disease the pains so dominate the scene as to justify a separate classification of such cases. The author has seen eleven such cases, all in adult men, and with a specific history in nine cases. The pains were the symptom for which relief was sought: They were severe and neuralgic in character. The danger of ataxy in such cases is small.

The extremities of the peripheral nerves are thought to be the source of the pains. Only the superficial pains can be relieved by local measures. Chloroform sprinkled on lint and covered with oiled silk, is often useful. Cocaine administered electrically is sometimes beneficial. Deep injections of cocaine are of little service in pains in the softer substance of a limb. As regards internal medication the coal tar products stand above all others. Phenacetin, antipyrine, and antifebrine are the ones most used and of the highest merit. Antifebrine is certainly the most effective. Sometimes the suffering is so intense as to require morphine. Chloride of aluminum, in doses of 5 to 10 grains thrice daily seems to lessen the tendency to recurrence and the severity of the pains. Salicylates sometimes have

the same effect. The use of iodides and mercury belong to the treatment of the disease rather than of the pains.

3. Pleurisy.—Gibson, in this article, gives the results of ten years' hospital experience. *Diagnosis.* Clinical examination by inspection, palpation, percussion, and auscultation, and the x rays forms one mode of diagnosis. The other mode consists mainly in cytology and bacteriology. *Cytology.* In order to examine the cellular elements of the exudate, the author uses an exploring syringe, centrifugates the fluid withdrawn, and prepares stained specimens, Jenner's stain giving the best results. The endothelial cells of the pleural membrane are found in varying numbers: also red corpuscles and leucocytes, either polynuclear neutrophiles or lymphocytes, the latter appearing to be the more stable. Pleural lymphocytosis is thought by some to be tantamount to pleural tuberculosis. As regards the bacteriology of pleural exudates, the commonest organisms are the pneumococcus, the streptococcus, the staphylococcus, and the tubercle bacillus. Examinations of the sputum, blood, and urine often yield useful collateral results. Of 118 cases of pleurisy seen, 65 were dry, 38 were serous, and 6 purulent. Tuberculous infection was present in 35 (29 per cent.): the pneumococcus was found in 27 (22 per cent.). In thirty-four cases it was impossible to assign any cause. A large lymphocytosis at an early stage in the exudation, and the absence of leucocytosis in the blood, are suspicious circumstances pointing to a tuberculous origin.

4. A New Blood Fluke.—Catto describes a new blood fluke found in the case of a Chinaman dying of cholera, to which he gives the name of *Schistosoma Cattoi*. Trematode ova were found scattered throughout the organs, and in the blood vessels adult trematodes, male and female. The case was confused by the presence in the intestine of nematodes (filaria). This new schistosoma resembles somewhat the well known schistosoma hæmatobium, but from which it differs in the following respects: Its habitat is mainly arterial, that of the African worm being reputed to be venous only. The ova' apparently exclusively affect the alimentary system, escaping by this route from the human host. The ova of *S. hæmatobium* affect mainly the urinary system. The abdominal viscera were more widely affected, and the geographical distribution differs, for no case of bilharziosis has yet been met with in China. The following worms and their ova were also found in the bowel: tricocephalus dispar, ankyllostoma duodenale, and ascaris lumbricoides.

7. Anthrax.—Lockwood and Andrewes report a case of anthrax of the cheek occurring in a horse hair worker, aged thirty-one years. The lesion had all the appearance of a malignant pustule, and anthrax bacilli were found in the clear fluid from the neighborhood of the slough. The duration of the case when first seen was four days. Excision would have meant considerable disfigurement: Sclavo's anthrax serum was therefore administered, forty c.c. of the serum being given subcutaneously. For two days the patient showed little improvement: the temperature varied from normal to

101.5° F., the slough increased a little in size, and the œdema and glandular swelling became more marked. No further dose of the serum was given: on the third day there was distinct improvement, and a culture from the edge of the slough showed no anthrax bacilli. Convalescence was rapid, but the slough did not come away until the twenty-first day of the disease, leaving a small granulating surface.

8. Nitroglycerin.—Elvy calls attention to the value of nitroglycerin in surgery. Not only in incipient senile gangrene, but in all cases of impaired circulation in which contracted arterial walls are present, it should be of great value.

GLASGOW MEDICAL JOURNAL.

December, 1904.

1. Eye Strain and Its Consequences, By RAMSAY.
2. Mycoses with Special Reference to Mycosis of the Eye-ball, By BUCHANAN.
3. Case of Traumatic Exophthalmus Pulsans, Ligature of Common Carotid. Cure, By KENNEDY.

1. Eye Strain and Its Consequences.—Ramsay states that his intention is to indicate the scope of this subject, and to arouse interest in it, rather than to attempt to give an exhaustive account of the evils which may arise from uncorrected errors of refraction. Eye strain is very often the unsuspected cause of headache and many other nervous disorders, hence it is always most important that any ocular defects should be corrected as soon as possible. In order that serious interpretation of symptoms may be avoided it is equally essential that other coexisting causes be not neglected and that their ætiological value be not underestimated.

MONTREAL MEDICAL JOURNAL.

January, 1905.

1. Health Resorts in Arizona, By VAUGHAN.
2. Quinine Amaurosis, with Report of a Case, By MATHEWSON.
3. Diagnosis and Treatment of Metrorrhagia, By MORROD.
4. The Placing of Perineal Sutures in Position Before the Laceration Takes Place, By LAPHORN SMITH.
5. Acute Intestinal Obstruction Occurring After Labor Caused by Hæmorrhagic Cyst, By SHAW.
6. Case of Extensive Gunshot Injury and Unusual Method of Closing a Large Granulating Surface, By KENDALL.
7. The Privileges of Medicine, By MCCRAE.

4. The Placing of Perineal Sutures in Position Before the Laceration Takes Place.—Laphorn Smith's advocacy of this plan is based upon an experience of four cases. His plan consists in introducing two or three silk worm gut sutures from side to side through the perinæum, just before the head reaches the perinæum, the patient being anesthetized. The ends of the sutures on either side are caught with a hæmostatic forceps, the two forceps hanging below the vulva and not interfering in the least with the progress of the labor. After the delivery of the placenta the perinæum is inspected and if laceration has taken place the sutures are tied, if not they are simply withdrawn, leaving only the insignificant puncture holes.

Letters to the Editor.

DELUSIONS DEPENDENT ON ABDOMINAL DISORDER.

126 EAST TWENTY-NINTH STREET,
NEW YORK, December 26, 1904.

To the Editor,

Sir: Your editorial under the above title in the issue for December 24th of your esteemed *Journal* interests me very much. Kindly permit me to call attention to some observations which may throw light on one mysterious abdominal disorder, namely, mucous colic.

Some distinguish between enteritis membranacea—a genuine enteritic catarrh—without colicky pains and colica mucosa, the latter characterized by the well known complex of symptoms, foremost colicky pains. Nothnagel calls this latter form a disease *sui generis*. As far as my own observations, confirmed by observations made by Dr. R. C. Kemp, show, mucous colic is not a disease *sui generis*, but one of the manifestations of gastropptosis, that is, abdominal ptosis.

The question if gastropptosis is the cause of mucous colic in all cases has to be decided by further observation, but it is easy to arrive at a division *ex jurantibus*. Thus far only some writers have paid attention to the coexistence of gastropptosis in cases of mucous colic, and I know of none, except my friend Dr. Kemp and some European colleagues, who, in treating of mucous colic, have considered the presence of gastropptosis. Gastropptosis is very frequent and mucous colic is rare, but this does not exclude the fact that mucous colic may be one of the manifestations of gastropptosis.

The relation of some ailments to gastropptosis has only been recognized since abdominal strapping in case of gastric atony has been practised in such an extensive way during the last few years. It has been found that there exists an important relation between dysmenorrhœa and gastropptosis. Cases of dysmenorrhœa in which uterine flexions or ovarian troubles existed and where gastropptosis was present have been promptly relieved by means of the abdominal plaster belt; relief of gastropptosis was relief from dysmenorrhœa. The same is the result in cases of mucous colic. German colleagues who during the last two years have made extensive use of the abdominal plaster belt have stated that this method of treatment did better service in many instances of uterine flexions than all the pessaries. This is easily explained. Gastropptosis is very often the cause of disorders of circulation, as well as of nervous disorders, and these disorders may in some instances cause mucous colic, dysmenorrhœa in others.

In general, the recognition of gastropptosis in its relation to a number of ailments, such as heart and lung diseases, anomalies of gastric secretions and motor functions is of far reaching importance.

A German writer, Dr. R. Weissmann, of Lindendelfs, writes:

"There exists a large number of chronic cases going from Pontius to Pilatus, and not a small

percentage of their ailments is connected with gastropptosis. Physicians in abdominal disorders, neuroses, neuralgias, should look for gastric atony, because they will in many instances relieve their patients from persistent and painful sufferings by means of the simple Rose belt."

On this occasion I wish to say that Dr. William H. Thomson was the first who appreciated the value of the strapping method when I spoke of it before a medical society five years ago, and that Dr. Robert Coleman Kemp has done the greatest part to make it popular among our American colleagues. I owe great thanks to these two and, last but not least, to Dr. E. C. Dent, who permitted me to give the method extensive trial in the Manhattan State Hospital on Ward's Island. In Germany it was Dr. Walther Nie. Clemm who introduced what Dr. Kemp has named "the Rose belt."

A. ROSE.

ENURESIS IN CHILDREN.

616 MADISON AVENUE,
NEW YORK, January 14, 1905.

To the Editor,

Sir: Under this heading Dr. J. Ullmann, of Buffalo, gives an interesting contribution to the *Journal* for December 31, 1904, but leaves out of detailed statement the chief cause of enuresis. Preputial adhesions are so predominantly the cause, particularly in girls, that no treatment should be instituted until that factor is definitely known to be out of the way. Girls need circumcision rather more frequently than boys do, anyway, for the reason that in girls preputial adhesions are more common than they are in boys, and the disturbances seem to be more marked on account of the more impressive nervous system of girls. Circumcision for girls is easily done. A general anæsthetic should be given—preferably nitrous oxide gas. Adhesions between the prepuce and the glans clitoridis are separated with the point of a thumb forceps. The prepuce is lifted with the forceps and trimmed off with a pair of curved scissors. An antiseptic powder is dusted over the field and a compress applied for a few hours. No sutures or ligatures are required, as the oozing is of small consequence. This work should be done by women physicians, but any physician of large practice who has not had a great many girl patients circumcised has missed the opportunity for having some very grateful patients and parents on his list.

ROBERT T. MORRIS.

EYE STRAIN.

85 BROAD STREET,
CHARLESTON, S. C., January 12, 1905.

To the Editor,

Sir: In your issue of December 24th there appears a reply to Dr. H. H. Seabrook's paper on What Should the General Practitioner Know of Ophthalmology, by Dr. F. D. W. Bates, of Ontario, Canada. Many articles have appeared from time to time on the effects of eye strain, notably

by Gould, of Philadelphia, and others, but it is strange how many men of experience and authority have attributed almost every known disease to eye strain, and yet but few have investigated the cause of the eye strain. It is well known that many errors of refraction are benefited by the removal of pressure symptoms in the nose. It frequently occurs that patients will state that their glasses have become too strong for them after the removal of nasal obstructions; therefore, if it is true that any diseases are produced by eye strain, which of course is not at all unnatural, is it not all the more proper that the cause of the eye strain, in the shape of muscular weakness, nasal obstruction, prolonged near vision, etc., should be removed, rather than to be content with glass correction. It is axiomatic in medicine that *causa sublata tollitur effectus*, but to attribute everything to eye strain and then fail to remove the true cause of the eye strain appears at least irrational.

W. PEYRE PORCHER.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of Wednesday, January 11, 1905.

The First Vice-President, Dr. FRANKLIN B. STAHL, in the Chair.

The Practice of Medicine in India.—Dr. ANNA M. FULLERTON (by invitation) read this paper. She said that the practice of medicine in India was attended with great difficulties in consequence of social and religious customs. These, with the dense ignorance and grinding poverty of the mass of the people, were responsible for the widespread epidemics which prevailed and which had baffled all the efforts of the English government for their suppression. There was no scientific system of native medicine. Herb doctors, known as "hakims," combined with their medical practice the use of charms and incantations, with offerings to the gods. Omens and astrology were believed in and much resorted to. Surgery was consigned to the barber. The condition of women was especially deplorable. High caste women could never see a male physician, but must be treated through the medium of ignorant midwives. Child marriage was an unending source of evil. Multitudes of girls of ten to twelve or even less were thus given over to outrage. Girls of even twelve years were known to become mothers in that land, and few attained the age of eighteen without bearing children. An increasing population under these physical conditions could not be a healthy or a vigorous one. On the part of the mother, shocking mutilations were often met with, for which repair of any kind was impossible. The hospitals established by the English government, and especially mission hospitals and dispensaries, were creating a sentiment in favor of Western medicine.

The Antitoxine Treatment of Diphtheria, with a Plea for Rational Dosage in Treatment and in Immunizing.—Dr. B. FRANKLIN ROYER, of the Municipal Hospital, in this paper, by a series of tables from the statistics of the boards of health in

Chicago, New York city, Brooklyn, and Philadelphia, proved an actual decrease in the loss of life in each city respectively of 5,400, 8,204, 951, and 1,853, a total for these four cities, without allowing for increased population, of 16,408 lives. By means of a preliminary table from the twelfth census a reduction of varying numbers in 100,000 population was shown in thirty large American cities.

By a table including 67,748 patients treated in the Metropolitan Asylums Board Hospital a decrease in death rate of 15.24 per cent. was shown. By a table from the South Department in Boston, reporting 16,544 cases, a decrease of 29.26 per cent. was shown. In the Municipal Hospital, reporting 10,219 cases, a decrease of 10 per cent. was proved.

The paper ended with a plea for a dose of antitoxine in proportion to the amount and situation of the exudate. Large doses were recommended in nasal, nasopharyngeal, and laryngeal diphtheria. A plea was made for a more general use of antitoxine as an immunizing agent. A strong plea was made for its use earlier in the disease, without waiting for culture returns.

The dose in use at the Municipal Hospital was: For tonsillar exudate (single), 2,500 units; purely tonsillar (double), 5,000 units; tonsillar exudate with pillars and uvula or pharynx involved, 7,500 to 10,000 units; nasal and any other part involved or for laryngeal diphtheria, 7,500 to 10,000 units. Repeat the dose in each type of disease in from twelve to twenty-four hours, depending upon the signs of improvement, and every twenty-four hours thereafter; when a large amount of exudate persisted, a dose of 5,000 to 7,500 units was given until a good amount of the exudate had disappeared.

Dr. H. M. FUSSELL said he had always felt, as expressed by Dr. Royer, that the cause of the high mortality of diphtheria in the Municipal Hospital was their receiving very bad cases. He also agreed with the writer that the conservatism of the practicing physician was responsible in part. A comparison of the treatment of diphtheria twenty years ago and now showed the value of antitoxine, for it was now possible to cure every case of diphtheria in which antitoxine was given in sufficient doses in the early part of the disease.

Dr. A. A. ESHNER referred to the intravenous employment of antitoxine in malignant cases of diphtheria and to its employment by the mouth.

Dr. ROYER said that they had used the intravenous administration of antitoxine at the Municipal Hospital for about sixteen months in cases that seemed hopeless, and had been gratified to see a few patients get well. He thought the method was well worth trying in malignant cases seen late. He had not mentioned the method, because he thought the practicing physician would see the cases early and give antitoxine.

An Unusually Severe Case of Acute Chorea Treated Successfully With Apomorphine.—Dr. MONTROSE GRAHAM TULL, in this paper, reported a case of acute chorea coming on gradually in a girl fifteen years of age, with menstruation not fully established, presenting symptoms of acute mania, guttural and unintelligible articulation, thickened tongue, covered with a confluent, morbilliform rash, and with incessant choreic movements. After all the accepted forms of treatment had been tried for

two weeks, with absolutely no effect, the services of Dr. Charles S. Potts were obtained. He endorsed the diagnosis and treatment, pronouncing it the severest case that he had ever seen. Everything else having failed, Dr. Tull concluded to try apomorphine in tentative doses. A fortieth of a grain was consequently administered hypodermically with a remarkable result. The choreic movements ceased in about three minutes and the child slept peacefully and quietly. A twentieth of a grain of apomorphine every three hours, by the mouth, was continued for three or four days in addition to arsenic, which she had taken from the beginning, with a perfectly uninterrupted recovery. Within two weeks the patient went to the seashore for the summer and soon became perfectly well.

The case seemed of value, as the diagnosis and earlier treatment were both reviewed and endorsed by a specialist of standing, and from the fact that practically all known means had been exhausted before apomorphine was used. The good results following so promptly upon the administration of apomorphine rendered it of special importance.

New Inventions.

A NEW GONORRHOEAL IRRIGATION APRON AND A STERILE BODY CLOTH FOR OFFICE USE DURING URETHRAL INSTRUMENTATION.

By FREDERIC GRIFFITH, M. D.,

NEW YORK.

Probably the most commonly employed treatment for gonorrhœa at the present day is irrigation in one form or another, and in this connection I desire to describe an apron which will protect a patient's clothing from wetting or staining during the carrying out of the procedure. A good idea of the shape and size required for ordinary office use may be obtained from Fig. 1, the

FIG. 1.—Author's irrigation apron for patients, made of rubber or mackintosh cloth.

apron being in reality a belted sleeve of mackintosh or rubber cloth containing an aperture for the penis. When applied, the protector is to be fastened about the patient's waist, and the penis drawn through the opening, the sleeve draining into a pail. The apron is to be turned inside out for cleansing by scrubbing with hot water and soap and bichloride solution.

A body cloth to take the place of the two or three towels required to be spread over a patient's clothing and person during office urethral examinations, passage of sounds or bougies as well as sundry operations about the penis, is pictured in Fig. 2. It consists of ordinary towelling cut in

FIG. 2.—Sterile body cloth with opening for the penis, for use during the passage of sounds and bougies.

three quarter yard lengths, in the centre of each being a three inch hemmed slit.

49 EAST SIXTY-FOURTH STREET.

Book Notices.

Poverty. By ROBERT HUNTER. New York, 1904: The Macmillan Company. London: Macmillan & Co., Ltd., 1904. Pp. xi-382. (\$1.50.)

The author states that his purpose is to define poverty, to estimate its extent in this country at the present time, to describe some of its evils, to indicate certain remedial actions that society may undertake safely, and to point out that the evils of poverty are not barren, but procreative. The book is divided into chapters on poverty, the pauper, the vagrant, the sick, the child, the immigrant, and conclusions.

The author believes that "there are probably in fairly prosperous years no less than 10,000,000 persons in poverty; that is to say, underfed, underclothed, and poorly housed. Of these, about 4,000,000 persons are public paupers. Over 2,000,000 workmen are unemployed from four to six

months in the year. About 500,000 male immigrants arrive yearly and seek work in the very districts where unemployment is greatest. Nearly half the families in the country are propertyless. Over 1,700,000 little children are forced to become wage earners when they still should be in school. About 5,000,000 women find it necessary to work and about 2,000,000 are employed in factories and mills. Probably no less than 1,000,000 workers are injured or killed each year while doing their work, and about 10,000,000 of the persons now living will, if the present ratio is kept up, die of the preventable disease, tuberculosis."

Certain reforms are proposed to remedy these deplorable conditions: "They would make all tenements and factories sanitary; they would regulate the hours of work, especially for women and children; they would regulate and thoroughly supervise dangerous trades; they would institute all necessary measures to stamp out unnecessary disease and to prevent unnecessary death; they would prohibit entirely child labor; they would institute all necessary educational and recreational institutions to replace the social and educational losses of the home and the domestic workshop; they would perfect, as far as possible, legislation and institutions to make industry pay the legitimate cost of producing and maintaining efficient laborers; they would institute on the lines of foreign experience measures to compensate labor for enforced seasons of idleness due to sickness, old age, lack of work, or other causes beyond the control of the workman; they would restrict the power of employer and of shipowner to stimulate for purely selfish ends an excessive immigration, and in this way to beat down wages and to increase unemployment."

The book is a plain, forcible statement of facts within the experience of an earnest worker in the field of relief, and deserves careful and thoughtful consideration.

Bacteriology and the Public Health. By GEORGE NEWMAN, M. D., F. R. S. E., D. P. H., Formerly Demonstrator of Bacteriology in King's College, London; Medical Officer of Health of the Metropolitan Borough of Finsbury, etc. Third Edition, Illustrated. Philadelphia: P. Blakiston's Son & Co., 1904. Pp. xx-497.

The author states that this new edition is an attempt to set forth a simple general statement of our present knowledge of bacteria, especially as they are related to the public health. He has sought to meet the requirement of the general student of hygiene and the medical officer of health, who need an elementary book that gives an adequate record of laboratory facts, and also views the subject broadly and particularly as it concerns the practical, every day problems of health and preventive medicine.

The first chapter, on the biology of bacteria, gives a careful description of the morphology and physiology of these organisms. The seven subsequent chapters describe bacteria in water, air, soil, food and waste and the technical and economic applications of bacteriology. Two chapters deal with bacteria and disease. There are interesting chapters on

the ætiology of tropical diseases, the question of immunity and antitoxines, and disinfection. The work is practical and likely to appeal to a large class of readers.

Précis d'auscultation et de percussion du poulmon et du cœur; signes physiques. Par J. VIRES, Professeur agrégé, et P. PAGES, Chef de clinique médicale à la faculté de médecine de Montpellier. Montpellier: Coulet et Fils; Paris: Masson et Cie., 1905. Pp. xvi-136. (Fr. 2.50.)

This little volume is a résumé of the author's lectures in his clinic in the Montpellier general hospital. He describes the phenomena of auscultation and percussion that are usually found, and explains them simply, avoiding speculative theories and holding fast to well established facts.

Miscellany.

Poisoning With Lysol.—Lange, in *Fortschritte der Medizin*, for September 20, 1904, states that he had the opportunity of seeing three cases of lysol poisoning in the course of one month, one of which resulted fatally. The general phenomena varied according to the severity of the intoxication. In the bad cases vomiting occurred soon after the lysol was ingested, this being quickly followed by unconsciousness and profound coma, so that the patients appeared to be dying. The heart seemed to be the organ which suffered most. Even in the lighter degrees of poisoning there were cardiovascular disturbances to a moderate extent, together with vomiting, headache, dizziness, and burning in the neck. In the mild cases the kidneys are intact, though there may be moderate and transient albuminuria with the characteristic color which accompanies carbolic acid poisoning. In the severe cases there is a toxic nephritis, or as Fries has termed it, a toxic glomeruli nephritis associated with severe uræmia. Additional phenomena in lysol poisoning are cyanosis, dyspnoea, and spasms. Motor phenomena of irritation were absent in the cases narrated by Lange. Autopsy reveals corrosion of the mucous membrane of the mouth, pharynx, and œsophagus and extensive injury to the mucous membrane of the stomach.

The proper treatment consists in free irrigation of the stomach. Even in cases which terminate fatally one can never be sure that the injury has been so extensive that irrigation will be contraindicated. If several hours have elapsed since the lysol was taken one must try to remove that which has reached the intestine with cathartics and high enemata. Especial care must be taken that none of the lysol is aspirated during vomiting, as irrigation for this would lead to the most serious complications. Hot tea, lemonade, or other soothing drinks must be administered in abundance to anticipate any irritation of the kidneys. Lysol can produce poisonous effects, not only when taken by the mouth, but also when used externally. Necrosis and gangrene of the skin have been thus produced. A case has been

reported in which death occurred after a one per cent. uterine douche. It should be sold by the apothecary under the same restrictions which are required for the sale of carbolic acid.

Observations Concerning Sudden Death from Heart Disease During Sleep.—Heitter, in *Fortschritte der Medizin*, for September 20, 1904, remarks that the prognosis in conditions of extensive changes in the heart muscle is indeterminable. In some cases in which there are the severest paroxysms of cardiac asthma and insufficiency of the heart muscle the patients unexpectedly get better and live for years, in others the patients seem to be in the best of condition in a general way, but some morning are found dead in bed. Anatomical changes in the heart muscle cannot always be brought forward as an explanation in such cases, for they are often absent or are not very conspicuous. One is forced to fall back upon nerve influences as a cause, which has been constantly invoked since the time of Goltz's experiments, as a probable means of stopping the heart's action. That these acute irritating influences must act injuriously upon a heart which is functionally incompetent more injuriously than upon a sound heart which has reserve force, is easily understood. In the presence of such irritating conditions death might easily result from sudden turning of the body, disturbing dreams, or other apparently slight causes, especially since they would occur at a time when the functional power of the body is usually at its lowest ebb.

An Antidote to Impertinent Curiosity.—Physicians often find it difficult to parry the idle questions of the curious. They might find it efficacious at times to resort to something like the following, which is said to have appeared in a newspaper a few years ago:

"Pardon me, sir," began the inquisitive passenger, bending in a confidential way over the back of the seat before him, "but what—"

"Adam was the first man," replied the dyspeptic looking man in front, in a cold gray monotone; "Moses was the meekest man, there never was any meekest woman; Columbus discovered America, John Hancock signed the Declaration of Independence. In the winter of 1847 and 1848 potatoes formed almost the sole food of the Irish peasantry. We are all indeed hurrying on toward eternity. White sheep eat more than black ones, because there are more of them. A door is not a door when it's ajar. Schley's name is pronounced 'Sly,' and golf is 'goff.' It is highly improper to wear a silk hat with a sack coat. There never was any such person as the Ahkoond of Swat. The great weakness of the American people is signing petitions without reading them. Yes, it is a good morning, and I have used everybody's soap; I—"

"Excuse me, but—er—er—what are you trying to—ah—get at?" interrupted the inquisitive one, much astonished at the reply his attempt had precipitated.

"The foregoing information," was the grim answer, in the same accentless voice, "is all I know about anything of any name or nature—biblical,

historical, statistical, biographical, geographical, conundrums or otherwise—past, present, or future, now and forever. I don't know anything else of any kind, character, style, shape, or color, good, bad, or indifferent. I not only do not know anything else, but I don't want to.

"My name is William Sufferin Smith; I am forty-three years old and a widower. I have the following relations, or, rather, they have me, namely: one mother in law, who was born to command; three brothers in law, who were born to be hanged, but have thus far escaped; two maiden sisters in law, of the vintage of 1842. Since the death of my wife these several relatives have lived on me like a pack of cannibals. My mother in law is sure my wife would have been alive now, if it had not been for my conduct. My brothers in law have differed with and also from me in politics and all other questions; they have worn my clothes, spent my money, and treated me with contumely and derision. One of my sisters in law is stage-struck, and the other has been subject to swooning spells for years. The whole outfit has ground into me their superior wisdom, their views of life, and their preferences in everything; they have henpecked, flouted, and abused me world without end. Yesterday I laid my coat and hat on the bank of the river, swam across, and disappeared in the woods, leaving my kith and kin to mourn me as dead. I am never going back unless I am overtaken and hypnotized. I don't know anything of interest to tell anybody, and I don't want to hear anything that anybody else has to tell. I want nothing in the world but peace. If you don't let me alone I'll throw my gripsack out of the window and jump after it. I have spoken." Thereupon the speaker withdrew into his shell, leaving the inquisitive passenger in a state closely bordering upon collapse.

Public Health and Marine Hospital Service:

Official List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending January 18, 1905:

GREENE, J. B., Passed Assistant Surgeon. Seven days' extension of leave of absence from January 7th, granted by Bureau telegram of January 4th, revoked.

TOWNSEND, W., Acting Assistant Surgeon. Department letter of November 22, 1904, amended to grant Acting Assistant Surgeon Townsend leave of absence for twelve days instead of thirty days from December 15, 1904.

Board Convened.

Board convened to meet at Washington, D. C., January 19, 1905, for the physical examination of an applicant for the position of Second Assistant Engineer, Revenue Cutter Service. Detail for the board—Assistant Surgeon General G. T. VAUGHAN, chairman. Assistant Surgeon A. J. McLAUGHLIN, recorder.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 21, 1905:

ALFRED, A. R., Surgeon. Detached from the *Solace* and ordered to the Naval Station, Cavite, P. I.

BUTLER, C. S., Passed Assistant Surgeon. Detached from the *Constellation* and ordered to the Naval Hospital, San Juan, P. R.

GARTON, W. M., Passed Assistant Surgeon. Detached from the Naval Hospital, Yokohama, Japan, and ordered home.

McLARTY, C., Pharmacist. Detached from the *Solace* and ordered to the Naval Hospital, Yokohama, Japan.

PLEADWELL, F. L., Surgeon. Detached from the Naval Dispensary, Washington, D. C., and ordered to duty at the Naval Hospital, Yokohama, Japan.

PLUMMER, R. W., Passed Assistant Surgeon. Detached from the Naval Hospital, San Juan, P. R., and granted leave of absence until February 15, 1905.

RODMAN, S. S., Passed Assistant Surgeon. Ordered to the *Pensacola*.

SELLERS, F. E., Passed Assistant Surgeon. Detached from the *Gloucester* and ordered to the *Franklin*.

STUART, A., Assistant Surgeon. Detached from the Naval Hospital, San Juan, P. R., and ordered to Washington,

D. C., for examination for promotion, and thence home to await orders.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending January 21, 1905:

EBERT, R. G., Major and Surgeon. Left from detached duty at Fort D. A. Russell, Wyoming, on fifteen days' leave of absence from January 11, 1905.

SMART, CHARLES, Brigadier General and Surgeon General. Retired as Colonel and Assistant Surgeon General, and advanced to Brigadier General on the retired list.

SWEAZY, VERGE E., First Lieutenant and Assistant Surgeon. Reported at the United States Army General Hospital, Washington Barracks, D. C., for treatment, from leave of absence.

Births, Marriages, and Deaths*Married.*

GROSS—MORGAN.—In Louisville, Kentucky, on Friday, January 13th, Dr. A. M. Gross and Miss Emma Morgan.

MURPHY—KEENAN.—In Brooklyn, N. Y., on Wednesday, January 11th, Dr. Joseph Paul Murphy and Miss Ella Keenan.

YOUNT—CRILEY.—In Prescott, Arizona, on Wednesday, December 14th, Dr. C. E. Yount and Miss Clara Criley.

Died.

BECKWITH.—In Atlantic City, New Jersey, on Friday, January 20th, Dr. Seth R. Beckwith, in the seventy-third year of his age.

CARR.—In Durham, North Carolina, on Friday, January 13th, Dr. A. G. Carr, in the fifty-ninth year of his age.

DEUELL.—In Saratoga, N. Y., on Friday, January 20th, Dr. E. Valencourt Deuell.

EDGERTON.—In Middletown, Connecticut, on Thursday, January 19th, Dr. Francis D. Edgerton, in the sixty-eighth year of his age.

GORDON.—In Jersey City, New Jersey, on Tuesday, January 17th, Dr. Leonard J. Gordon, in the sixty-first year of his age.

HARDING.—In Blairsville, Pennsylvania, on Tuesday, January 10th, Dr. James Leslie Harding, in the forty-sixth year of his age.

HARRISON.—In Grand Rapids, Michigan, on Thursday, January 12th, Dr. George W. Harrison.

HERVEY.—In Indianapolis, Indiana, on Friday, January 6th, Dr. James W. Hervey, in the eighty-second year of his age.

KANE.—In Kansas City, Missouri, on Monday, January 9th, Dr. J. H. Kane, in the forty-ninth year of his age.

MATHEWS.—In Manchester, Virginia, on Thursday, January 12th, Dr. Thomas P. Mathews, in the seventieth year of his age.

McJUNKINS.—In Toccoa, Georgia, on Tuesday, January 10th, Dr. John McJunkins.

NORRED.—In Minneapolis, Minnesota, on Wednesday, January 11th, Dr. William A. Norred, in the thirty-fifth year of his age.

O'LEARY.—In Cleveland, Ohio, on Wednesday, January 18th, Dr. Arthur O'Leary.

PELTZ.—In Philadelphia, on Friday, January 13th, Dr. Josiah Peltz, in the sixty-fourth year of his age.

POLIN.—In Springfield, Kentucky, on Saturday, January 14th, Dr. D. O. Polin, in the seventy-seventh year of his age.

SAUNDERS.—In Charleston, South Carolina, on Tuesday, January 10th, Dr. J. G. Saunders, in the fiftieth year of his age.

WOODBURY.—In Washington, D. C., on Sunday, January 15th, Dr. Henry E. Woodbury, in the eightieth year of his age.

YOUNG.—In New York, on Thursday, January 19th, Dr. John W. Young, in the twenty-sixth year of his age.

SOME OBSERVATIONS ON THE DIAGNOSIS OF RENAL CALCULUS, WITH SPECIAL REFERENCE TO DIAGNOSIS BY MEANS OF THE X RAYS.*

By ALEXANDER B. JOHNSON, M. D.,

NEW YORK.

According to their occurrence we may divide renal calculi into two groups: Primary, when the stone is formed in a previously healthy kidney; and, secondary, when the stone formation occurs as a result of disease already existent in the organs.

From the diagnostic point of view the primary calculi are of greater interest.

In the second class the disease of the organ itself usually forms the foreground of the picture, in which the signs and symptoms due to the presence of stone are more or less completely lost to view, except in those cases in which the stone causes temporary or permanent obstruction to the passage of fluids from the ureter to the bladder.

In their chemical composition kidney stones may be classed in several groups. Commonly, uric acid and oxalate of lime stones are grouped together.

The stones, consisting chiefly of alkalies and the salts of the alkaline earths, form a second group.

The cystin, xanthin, and indigo stones form a third.

This grouping is more or less artificial, inasmuch as stones consisting of a single ingredient are quite rare and we usually find that several ingredients are mixed in varying proportions. The mixture may be, and usually is, an intimate one; or, on the other hand, the different ingredients may be arranged more or less regularly in concentric layers, each layer consisting of a single ingredient or of several ingredients. This

mixture is found in the majority of primary as well as of secondary, calculi.

The bearing of these facts upon the x ray diagnosis of renal calculus will be mentioned in another place.

The designation of stones as stones of calcium oxalate or stones of uric acid, for example, usually indicates merely that this or that ingredient predominates. Stones of nearly chemically pure oxalate of lime, uric acid, cystin, or other ingredient are occasionally found, it is true, but their occurrence is the exception rather than the rule.

Henry Morris gives the following figures, derived from 73 published cases, in regard to the relative frequency of occurrence of different types of kidney stones:

Calcium oxalate.....	44	per cent.
Uric acid.....	22	per cent.
Phosphatic.....	16.8	per cent.
Mixed.....	14	per cent.
Calcium carbonate, and Cystin.....	} Rare.	

James Israel, amongst 49 cases of primary renal calculi in his own practice, found

21 stones of phosphates and carbonates.
10 uric acid and uric acid salts.
16 oxalates.
Uric acid and urates constituted 20.4 per cent.
1 xanthin.
1 sulphur

A careful perusal, however, of the case histories published in Professor Israel's work shows that a chemical analysis was made of the stones removed in most of his cases, and that the stones containing uric acid and urates alone without oxalate of lime or the phosphates and carbonates of the alkaline earths in considerable quantities, were quite the exception: for example, of stones removed from 74 cases, including both primary and secondary calculi, 26 consisted partly of oxalate of lime; 31 contained a considerable proportion of phosphates; in 9 the character of the stone is not specifically stated, but the history of the cases would indicate that these were phosphatic stones, or, at least, contained a considerable proportion of phosphates. One stone consisted

* Read before the Society of the Alumni of the New York Hospital.

chiefly of sulphur and one of xanthin. The pure uric acid and urate stones numbered 6—that is to say, 8 per cent. of the entire number.

In order to conduct certain experiments in regard to the detection of renal calculi by means of the x rays I collected a considerable number of calculi from different sources, from surgeons of my acquaintance and from museums.

I chose only such calculi as were believed to consist solely or chiefly of uric acid. Upon having these calculi subjected to chemical analysis, out of 20 stones acquired from various sources, but one was found to consist of uric acid or its salts in what might be fairly called a pure state. The others contained a variable quantity of oxalate of lime or of phosphates.

The bearing of these observations upon the x ray diagnosis of kidney stone will be mentioned later. Theoretically, it is generally assumed that for the formation of stone an organic nucleus is necessary, but it is evident that such a nucleus may consist of a single degenerated blood cell or the minutest fragment of mucus.

An unduly concentrated urine is supposed to favor the production of calculus, and urine containing an excess of a variety of ingredients may be assumed to be a condition favorable for the precipitation of such ingredients.

The disease appears to be slightly more common in men than in women, and climatic conditions and qualities of drinking water appear in certain not entirely evident ways to favor the condition.

Mode of life, apparently, has some influence; a sedentary life, a nitrogenous diet, and the use of alcohol seem in some cases to determine the formation of calculus. On the other hand, among the people who subsist chiefly upon carbohydrates and who live and work vigorously out of doors, renal calculus is common enough.

In by far the largest proportion of cases, the formation of renal calculus takes place in the renal pelvis or one of the calices.

The occurrence of kidney stone in the parenchyma of the organ belongs to the surgical rarities; a few such cases only have been reported.

In size and shape the greatest diversity exists. The stones may be minute, constituting the condition known as gravel, or, in certain instances, a stone or stones weighing several ounces have been removed from the kidney.

The stones may be rounded or irregular in shape, or may form a complete cast of the dilated pelvis, calices, and beginning of the ureter.

The x rays have demonstrated that a larger proportion of stones than was formerly supposed pass out of the pelvis of the kidney and find their

way downward to lodge in the intrapelvic portion of the ureter; thus Leonard found that among 30 cases in which the diagnosis of stone was made by means of the x rays, the stones occupied the ureter in 19 cases.

CHANGES PRODUCED IN THE KIDNEY BY THE PRESENCE OF STONES.

The changes produced in the kidney by the presence of stones in the pelvis or in the ureter depend upon a variety of conditions.

An important distinction is to be drawn between the cases in which the kidney remains in an aseptic condition and those in which infection occurs.

So long as no infection takes place the changes consist in an interstitial nephritis and a fatty or hyperplastic change in the fibrous and fatty capsules of the organ.

If the ureter becomes obstructed the kidney may suffer in two ways. In case the obstructive process is gradual, the pelvis of the kidney may become dilated and the kidney itself may be changed into a thin walled sac, with disappearance, partial or complete, of the proper secretory and excretory substance, the condition, namely, of hydronephrosis.

Sudden and complete occlusion of the ureter which persists leads, not to dilatation, but to atrophy of the kidney. The kidney becomes converted into a dense mass of fibrous tissue containing much fat, from which the kidney substance disappears.

In case infection occurs, the various phenomena of pyelitis, pyelonephritis, infected hydronephrosis, abscess of the kidney, or pyonephrosis are produced.

An extension of the infectious process beyond the kidney itself results in perinephritis and in abscess in the neighborhood of the kidney.

In certain rare cases pressure necrosis caused by the stone may lead to perforation of the renal pelvis or parenchyma, with the production of areas of granulation tissue in the perinephric structures; and, in the absence of infection, this condition may exist without the formation of pus.

The symptoms and physical signs of calculus formation may be considered under several heads:

- 1st. Subjective symptoms.
- 2nd. Changes in the urine.
- 3rd. The physical signs to be recognized by palpation.
- 4th. The evidence to be derived from the cystoscope, ureteral catheter, and ureteral sound.
- 5th. The evidence to be derived from x ray examinations.

1st. The subjective symptoms of kidney stones as well as of stone in the ureter—consist of pain and of disturbances of urination. The pains may

be broadly said to consist of sudden severe attacks of pain of longer or shorter duration, and of more or less constant, though usually intermittent, pain of a less severe character. The severe attacks of pain are often spoken of as attacks of kidney colic.

The typical kidney colic is characterized by a sudden onset and is of excruciating character; it is felt in the kidney region affected, along the course of the ureter, sometimes in the bladder, the testes, and external genitals. The pain may also radiate upward into the shoulder or down the thigh along the distribution of the anterior crural nerve. The pain is sometimes accompanied by vomiting, great prostration, sweating, by a constant desire to urinate, and in some cases by general convulsions. The attack may last for a few minutes, for hours, or for several days. The pain generally subsides suddenly, leaving the individual quite free from discomfort.

This typical history of an attack of renal colic is clinically the exception rather than the rule. Any one of the characteristic symptoms may be absent. The pain may be referred in such a manner as to lead to suspicion of disease of a different character. The symptoms may point to acute gastrointestinal disturbance. The pain may closely resemble an attack of biliary colic. If the pain is localized in the epigastrium, is a general abdominal pain, or is felt chiefly on the right side of the abdomen, low down, it may be mistaken for disease of the appendix.

There are numerous instances in which kidney stone has been mistaken for scoliosis and for tuberculous disease of the bodies of the vertebrae.

It is also to be remembered that a number of conditions, other than stone, affecting the kidney may give rise to precisely the same train of symptoms.

The invasion of the kidney structure with tuberculosis, with its accompanying congestion and tension of the kidney capsule, may produce identical symptoms and be accompanied by characteristic hæmaturia.

A new growth into which a hæmorrhage takes place may exactly simulate a renal colic.

It is asserted by several authorities on the subject, although denied by others, that the pain may be located upon the opposite side of the body. My own observation supports the affirmative view.

Hæmorrhagic pyelitis may give rise to symptoms precisely the same.

Kinks in the ureter, in cases of movable kidney, may give rise to similar attacks.

In general, any condition which produces a sudden increase in the intracapsular tension of

the kidney or which obstructs the ureter may accurately simulate an attack of renal colic, an intraabdominal tumor, or an aneurysm, by pressure for example.

There remain to be considered the very considerable group of cases in which the stone remains, so to speak, quiescent, giving rise to no symptoms at all, or at most to a slight amount of discomfort from time to time, or to symptoms hardly to be differentiated from those of ordinary functional gastrointestinal disturbance.

In another class of cases the typical symptoms of renal colic are entirely wanting, and the patient may suffer from constant or intermittent pain, sometimes referred to the region of the kidney often to the bladder, and not infrequently to distant parts of the body, as, for instance, the sole of the foot.

A large number of these cases are treated for bladder disturbance, none of the symptoms being referred to the kidney.

Calculous Anuria.—A patient who suffers from kidney stone may suddenly be seized with suppression of urine. If the other kidney is absent, destroyed, or seriously diseased, or if both ureters are obstructed at the same time, the condition will usually end in death in a few days, unless relieved by operative removal of the stone obstructing the ureter, or unless, as sometimes happens, the obstruction is partly or entirely overcome by natural means.

If the other kidney is sound it usually continues its function. Sometimes a reflex anuria, usually of a temporary character, may occur in this sound kidney also. In fact, it is probable that such reflex anuria in a sound kidney rarely if ever endures to a fatal issue.

The symptoms of the onset of urinary suppression from calculus differ to some extent from the ordinary symptoms of uræmia.

At the beginning there is usually pain, referred to the kidney region or to the lumbar region and down the course of the ureter. The pain may last throughout the attack or more often will subside after hours or days.

Many of the symptoms may be referred to the bladder as in an ordinary attack of renal colic.

When the obstruction is absolute, no urine may be passed after the beginning of the attack. If incomplete or intermittent, oliguria may alternate with polyuria. These are the cases in which hydronephrosis develops. The suppression is rarely so absolute as in ordinary cases of uræmia, and, usually, small amounts of urine of low specific gravity will be voided, even though the case is to end fatally.

In case the useful kidney is hydronephrotic a

certain tolerance appears to be established; and even if the obstruction is not overcome death may be delayed for many days.

When uræmic symptoms develop, they resemble those accompanying other forms of suppression, except that vomiting is more common and diarrhoea less so.

CHANGES IN THE URINE.

The evidences furnished by the urine are valuable, although there are no data to be obtained from the urine, which enable us to make a certain diagnosis of kidney stone.

The urine may be entirely free from abnormal ingredients.

In certain cases the examination of the urine suggests merely a hyperæmia of the kidney.

The urine frequently contains blood in small amount, constantly or only at intervals.

The blood in many cases is only discoverable under the microscope. There will sometimes be a quantity of albumin present in the urine, slightly in excess of the amount of blood or of the number of pus cells, if such are present.

Sharp, and even dangerous, hæmorrhage may occur, but such cases are the exception.

The type of bleeding which furnishes us with the strongest evidence of the presence of calculus is small in amount and frequently microscopic.

The number of blood cells present in the urine is often increased by muscular exertion and entirely disappears when the individual is kept quiet.

When the hæmorrhage is coincident with an attack of renal colic the bleeding usually continues for hours or days after the colic has subsided.

Blood casts of the renal tubules do not occur, nor are blood casts of the ureter at all common.

When the hæmorrhage is severe we must depend upon other physical signs and symptoms to exclude the presence of a malignant growth, an invasion of the kidney with tuberculosis, or the presence of a hæmorrhagic pyelitis.

A moderate increase in the number of leucocytes contained in the urine, or even a mild catarrhal pyelitis, may exist without infection.

In the absence of lesions of the lower genito-urinary tract, the presence of a small quantity of blood, a trace of albumin, a moderate number of leucocytes in the urine is, when combined with attacks of renal pain in the absence of tubercle bacilli and failure to appreciate a notable enlargement of the kidney on palpation, and especially if there is a previous history of a passage of calculi, strong presumptive evidence of the presence of stone.

When infection of the kidney has taken place and the urine is loaded with the products of inflammation, it is scarcely possible by urinary analysis to say whether the primary cause of the trouble is stone or some originally infectious process: indeed, a stone or stones are often found in the pelvis of pyonephrotic kidneys, apparently as a secondary condition to the suppurative nephritis, and also in tuberculous kidneys in which secondary purulent infection has occurred, stone is not very rare.

These secondary cases of renal calculus present themselves to us more commonly as cases of pyonephrosis, perinephritic abscess, or other serious destructive lesion of the kidney, in which the stone plays a subordinate rôle from a pathological as well as from a diagnostic point of view.

In those cases of primary calculus where infection occurs, a series of signs and symptoms are exhibited, complex in character and due in part to the presence of stone; either set of signs and symptoms may predominate in any variety of prominence.

THE PHYSICAL SIGNS AND SYMPTOMS TO BE OBSERVED BY PALPATION.

Manifestly, the only positive signs of the presence of kidney stone discoverable by palpation are, the actual appreciation of the stone under the examining fingers or a sensation of grating obtained by moving one stone upon another.

Such signs are rarely observed, and only in cases presenting stones of unusual size or in the persons of individuals unusually flabby and with thin abdominal walls. Such cases must of necessity belong to the surgical rarities, and although occasionally observed and reported by surgeons, these signs can scarcely constitute a common means of diagnosis.

A physical sign to which many surgeons have attached much importance is the occurrence of pain elicited by a light quick blow upon the last rib of the affected side. In the absence of pronounced changes in the urine and of other signs of serious deorganization of the kidney, this sign is often given a high diagnostic value, when taken in connection with subjective symptoms such as commonly accompany the presence of a stone in the kidney.

Since the presence of a stone in the renal pelvis is not incompatible with a kidney normal in size, shape, and position, the existence of a tumor of any description corresponding to the situation of the kidney, or the absence of such a tumor, is not necessarily significant of the presence, or, on the other hand, of the absence, of stone.

Stone impacted in the lower end of the ureter may occasionally be felt *per rectum* or *per vaginam*.

The cystoscope and ureteral catheter sometimes afford useful aid. A stone projecting through the opening of the ureter into the bladder can be seen through the cystoscope.

The ureteral catheter, when passed into the ureter, may meet with obstruction, and such obstruction may be due to stone.

A positive diagnosis, even, is possible and has been made by inserting a wax coated bougie into the ureter. The bougie coming in contact with the stone was moved back and forth and scratch marks were found upon the surface of the wax, thus showing the presence of some hard rough substance (Kelly).

The general conclusion must, then, be drawn, that in by far the largest proportion of cases no positive diagnosis of renal calculus can be made by the ordinary methods of examination.

There remains to be considered the value of the x ray examination in these cases. The opinions of different observers in this field vary to some extent.

On the one hand, Dr. Charles L. Leonard, of Philadelphia, regards the x ray diagnosis of kidney stone as a method of almost mathematical accuracy. His opinion is supported by observations made upon nearly three hundred cases. In sixty or more of these cases a positive result has been obtained by x ray examination. The others have been negative, and he states that in not more than three or four instances have his conclusions been proved erroneous.

On the other hand, Henry Morris, of London, in his recent work on the *Surgery of the Kidney*, places but little reliance on the evidences furnished by the x rays. He believes that, though an occasional diagnosis of a kidney stone may thus be made, the negative evidence is almost valueless.

Professor James Israel, of Berlin, entertains similar views.

Albers Schöneberg believes that uric acid, xanthin, and cystin stones are in general not capable of demonstration by means of the x rays. To recognize them in this way is as hard as is the case with biliary calculi—that is to say, they are only demonstrable under favorable conditions. He finds, on the other hand, that stones composed of phosphate and of oxalate of lime cast extraordinarily clear shadows on the photographic plate.

Bevan (*Annals of Surgery*, March, 1901) says that, while formerly only the positive results of an x ray examination for kidney stone were valuable, now the negative results have become of value. He says: "If the kidney itself is plainly

recognizable as a shadow upon the plate, a stone will show if it be present, and if the shadow of the kidney is clear and no shadow of a stone appears, a stone cannot be present."

Hutchinson (*Medical Press*, August 14, 1901; *British Medical Journal*, October 19, 1901) draws the following conclusions:

1st. The x rays render an exact diagnosis possible, except in the case of a very stout individual or a very small stone. The position, size, and number of the stones can be determined by this means, etc.

Among American surgeons in general no very great reliance is placed on the x ray diagnosis of kidney stones. It is, of course, agreed that positive results are often obtained, but since a large proportion of the individuals who suffer from symptoms leading to the suspicion of renal calculus have some other cause as a basis for their troubles, the negative diagnosis is of greater importance than is the positive detection of a stone. It is generally admitted that oxalate of lime and phosphatic stones may be detected, and under favorable conditions excluded, by the use of the x rays. It is asserted, on the other hand, that uric acid stones cast such faint shadows upon the photographic plate that a negative result is not conclusive.

My own experience is limited to about 125 cases examined. I have not succeeded in detecting a pure uric acid calculus. Among the earlier cases examined was one in which, owing to want of experience, a shadow upon the plate was believed to be a stone, but was found to be due to a defect in the gelatin. The patient was operated on and no stone was found. In thirty cases a positive diagnosis was made by means of one or more skiagraphs, and the presence of stone was confirmed by the operation.

Of the stones discovered, in 26 cases the stone or stones were in the pelvis of the kidney or extreme upper end of the ureter. In 4 cases the stones were in the pelvic portion of the ureter.

One stone of oxalate of lime weighing less than a grain and a half was found on three different occasions in three different situations in the ureter, each successive time at a lower level. The stone finally passed and was weighed by me. As stated, it weighed $1\frac{1}{2}$ grains. The patient suffered no further discomfort. He was a man with a thick abdomen, but of short stature. His weight was 175 pounds.

The stones discovered have varied from a fraction of a grain to nearly an ounce in weight. They have all either contained oxalate of lime in appreciable quantity or have consisted largely of phosphates. Several stones appeared to consist of

uric acid merely, but chemical analysis showed at least 10 per cent. of oxalate of lime in every instance.

In several cases no picture has been obtained good enough for a diagnosis. The failures have been due to:

- 1st. Great thickness of the body of the patient.
- 2nd. Imperfect working of the electrical apparatus.
- 3rd. Improper handling of the photographic plate in the dark room.
- 4th. Imperfect photographic plates.

Among the cases in which a negative diagnosis has been made, in one I failed to detect the presence of several small calculi in the end of the ureter. In this case the x ray plate did not extend far enough downward to include that portion of the ureter in which the stones were afterward felt *per vaginam*.

While I do not intend to enter into an elaborate description of the apparatus and the technique employed, I believe that a general view of the methods, the difficulties, and the apparent limitations of the procedure at the present time, may not be devoid of interest to the society.

To insure success in the radiography of kidney stones, the following conditions must be fulfilled:

The electrical current used to excite the tube must be of high voltage and of considerable amperage. The best coils and large static machines answer this requirement perfectly.

The x ray tube used must permit the passage of such a current continuously for several minutes without much change in internal resistance; and, to produce the best effects, this should be true, although the resistance or vacuum of the tube is relatively low at the start. This condition is, in my experience, hard to fulfill.

A tube of relatively low resistance produces rays showing upon the photographic plate slighter differences of density in the structures through which the rays are passed; but, as the result of the passage through such a tube of a powerful current, the tube usually becomes heated with a further fall of resistance and the production of rays of inadequate penetrative power. A tube of high resistance tends to preserve its vacuum resistance better, but the x rays given off from a tube, the resistance of which is very high, possess the penetrative power to a high degree; they penetrate all the structures of the body more nearly in an equal manner, and thus produce radiographs, showing but little contrast between tissues of different densities. Such pictures are what are described in photography as "flat" negatives. The positive and negative value of such a picture of the

body of an individual supposed to be suffering from renal calculus is not great.

In order to establish the absence of stone it is necessary, as has already been pointed out by a number of observers, to produce a negative which shall show such marked contrasts between structures varying but little in density that even the smallest calculus will cast a definite shadow. This may usually be done in young persons and in slender adults. It is, on the other hand, exceedingly difficult when the individuals are large and stout.

I have been unable to make up my mind as to the exact cause of this difficulty. Probably pictures of fat people are hard to obtain for several reasons. In the first place, the actual thickness of tissue to be penetrated is much greater, consequently the exposure must be longer; moreover, the length of the exposure must be still further increased, because it is dangerous to expose the skin for a long period to the action of the rays unless a considerable interval exists between the tube and the skin, twelve inches at least. There seems to be some reason to believe that long exposures excite in the tissues themselves secondary foci of x rays, which affect the photographic plate and produce a blurred and indistinct picture.

The thickness of the fat upon the buttocks and upon the back raises the skeleton and the kidney some distance away from the underlying photographic plate. A further blurring and want of detail in the image is thereby produced. This is notably the case in women possessing large thick buttocks.

The movements of the abdominal walls of fat persons also seem to produce a clouded appearance on the photographic plate.

I have succeeded occasionally in producing satisfactory negatives of very stout people. The conditions were as follows: The tube used was the water cooled tube, devised by Dr. E. Grunmach, and sold by the Kny Scherer Company. It has always happened to be an entirely new tube, of relatively low resistance, showing a brilliant apple green fluorescence and illuminating the fluoroscope brilliantly, and producing vivid fluoroscopic images of the flesh and bones of the wrist and forearm. Such a tube will produce a vivid picture of the hand on the screen at a distance of many feet, and the tube has always possessed the peculiarity that its resistance fell but little even after some minutes of running at its full capacity.

I have never taken a successful picture of a kidney stone with a tube which had been used many times, or with one which had become coated with

the purplish black film which forms in old tubes. My best pictures have been taken with the Wehnelt electrolytic interrupter, with rather a heavy platinum electrode having a considerable amount of platinum exposed in the acid, thereby permitting the use of a current of considerable amperage and relatively slow interruptions.

The exposures for large stout people have varied from ten to fifteen minutes with the anticathode about thirty inches from the photographic plate. For thin individuals these exposures have been shortened one half.

I do not know whether my failure to obtain good pictures with any but new tubes is due to a defect in the apparatus used or not, but I am inclined to think that such is the case, since the experience of others does not entirely agree with my own.

This may depend upon the fact that, with the machine I use, a discharge occasionally occurs through the tube in both directions. Hitherto I have been unable to prevent this when driving the tubes to their fullest capacity, and they are soon destroyed.

It has sometimes happened that, with all the conditions apparently favorable and with the greatest pains in technique, the pictures have been utter failures.

Sometimes I have been able to account for such failures by imperfections in the photographic plate or in the technique of development, and sometimes I have not been able to explain the failure. A serious handicap has been also, in these cases, the necessity of taking the pictures singly and at rather long intervals, on account of the danger of burns and of the unwillingness on the part of the patients to permit a number of exposures to be made. The very great expense also of new tubes for each case has prevented the best obtainable results.

The conclusions I have been able to draw from my experience are as follows:

The positive diagnosis of kidney stone by the x rays is reliable and of great practical value.

The negative diagnosis of kidney stone by the x rays is reliable and valuable up to a certain limit.

If pictures of a proper quality are obtained, calculi of oxalate of lime and phosphates can be excluded. Pure uric acid calculi cannot.

Pictures of a proper quality can be obtained with ease in children and slender adults of both sexes.

Such pictures can usually be obtained by repeated trials in well nourished adults.

When patients are unusually stout, when the abdomen is very thick and the buttocks are large, the conditions are extremely difficult, and only occasionally will a satisfactory result be obtainable with the present form of apparatus.

12 EAST FIFTY-EIGHTH STREET.

BINASAL HEMIANOPSIA; A CASE OF NEURITIC OPTIC ATROPHY WITH BINASAL HEMIANOPIC FIELDS.*

By WILLIAM T. SHOEMAKER, M. D.

PHILADELPHIA.

Hemianopsia means half blindness, but unfortunately this very useful and expressive term does not indicate of itself the anatomical cause of the blindness. Partly for this reason, confusion is at times experienced in properly classifying certain forms of disease having as a prominent symptom half blindness, as applied to the visual fields. This is notably true of those rather rare cases in which the nasal field of one or both eyes fails. Nineteen such cases have been reported, mostly under the diagnosis of binasal or nasal hemianopsia. Such a diagnosis is purely symptomatic and should be discarded, as has been suggested by Rakowicz (1) and others before him.

One thing necessary before this can be done is a greater unanimity in the understanding and acceptance of the term hemianopsia. Another necessity is a willingness on the part of those reporting cases, to report so far as possible actual conditions, instead of some rare symptom.

The classical definition of hemianopsia calls for a half defect in the field of vision of each eye, symmetrically placed, and caused by a common intracranial lesion. The basis of this definition is the semidecussation of the optic nerve fibres in the chiasm, and by it are excluded affections of the visual fibres distal to the chiasm, or affections of the optic nerve in any part, and intraocular affections. There has been no difficulty in excluding hemianopsia as a diagnostic term when it is of intraocular origin, as for example, occurring in the course of glaucoma, but with affections of the optic nerve, it has been different; they have not been excluded as being productive of true hemianopsia, and in particular of binasal hemianopsia.

The possibility of binasal hemianopsia within the definition has been frequently denied, and still more frequently doubted. That it can result from a chiasm lesion must be acknowledged to be an anatomical impossibility, in view of the investigations of Henschen, Dimmer, Hosch, v. Monakow, and Schmidt-Rimpler. These investigators have studied descending degeneration of the visual fibres with coincident results. The relative situation of the crossed, uncrossed, and macular fibres throughout their course to the primary optic ganglia, but especially in the nerve and chiasm, has been very definitely settled.

* Read before the Ophthalmic Section of the Philadelphia College of Physicians.

Fig. 1. Diagram of the optic chiasm, from Willbrand and Sönger (after Henschen).
 ++ = Crossed fibres
 .. = Uncrossed fibres
 ... = Uncrossed fibres of papilla macular bundle

FIG. 1.—Diagram of the chiasm.

The fibres in question, or those supplying the temporal half of the retina; the uncrossed fibres, of the fasciculus lateralis, course as follows: In the nerve, next the bulbus, this bundle divides into two equal portions, between which, outwards and downwards, lies the macular bundle. These two bundles approach each other, and unite about the point where the central retinal artery enters the nerve, to form a crescent shaped bundle situated peripherally below and out. The crossed fibres form a compact and uninterrupted bundle throughout the nerve, with a dorsomedian position.

Upon entering the chiasm, the uncrossed fibres divide into a number of radially arranged layers, like superimposed leaves. A certain number of fibres approach the periphery of the chiasm; the principal mass, however, lies more toward the middle, and those fibres are mixed with crossed and crossing fibres.

In the chiasm, the crossed fibres pass from a dorsomedian position which they have in the nerve, to a ventromedian position which they keep in the tract. The uncrossed fibres pass in an opposite direction; ventrolateral fibres in the nerve become dorsocentral in the tract. The crossed fibres arrange themselves into a number of horizontal processes which push between the uncrossed bundles, which are in horizontal layers. Many of the crossed fibres reach the periphery of the chiasm. From this arrangement and mixture of crossed, crossing, and uncrossed fibres in the chiasm, it will be seen that at no point in the chiasm do the uncrossed fibres form an isolated bundle, and that nasal hemianopsia due to a chiasm lesion must be impossible. Willbrand and Sönger (2) are the latest authorities for this statement.

It likewise follows that the graphic production of nasal hemianopsia, by the placing of a lesion in the lateral angle of the chiasm, as found in so many textbooks, is an error.

As to the course of the crossed and uncrossed fibres in the tract, opinions differ somewhat. A few observers believe these fibres to be mixed,

but Henschen and the majority of investigators have found the uncrossed bundle intact as such throughout.

A lesion which would destroy this bundle, and this alone, would produce nasal hemianopsia, and is of course possible. The only probable lesion of this kind, however, would be an atrophy of this bundle, which might be called for want of a better name a selective atrophy. A pressure lesion which, exerting itself from without, would limit its destruction with such nicety to the uncrossed fibres is difficult to conceive of, and a similarly limited inflammation, interstitial in character, would be most improbable on account of the almost total absence of pial processes and septa entering the tract. This anatomical arrangement will be referred to below. Gowers in a letter to Eales concerning the latter's case of binasal hemianopsia, wrote that he thought nasal hemianopsia had never been due to disease behind the chiasm, and that he could not conceive that it could be so produced.

We have still left in which to place the offending lesion, the optic nerve and, out of respect to the case of Herschel referred to later, the visual centre, or subcortical regions. Degeneration of the visual fibres has not been carried with certainty beyond the external geniculate body, therefore the possibilities of a lesion situated between this point and the cortical visual centre are purely speculative.

The writer is in accord with those who believe that so called nasal hemianopsia is in most instances a symptom of optic nerve disease. A brief examination of the cases reported will show reason for this when the optic nerve conditions are considered. The cases are arranged chronologically as reported.

I. *v. Graefe* (3), in 1856, mentioned a case of binasal hemianopsia, the only one he had seen, which he considered of central origin. Aside from the symptom of hemianopsia, the data in the case were insufficient to warrant any explanation or special diagnosis.

II. *Mandelstamm* (4) (1866) described a case observed in Pagenstecher's Institute. This case showed neuroretinitis, which resulted in total blindness.

III. *A Second Case by Mandelstamm* (5) (1866) showed neuroretinitis and perivascularitis. There was no sharply defined dividing line.

IV. *Mooren* (6) (1867) reported two cases. The first case was one of traumatism, the patient falling from a considerable height. Ophthalmoscopically, all the signs of optic atrophy were pronounced.

V. *Mooren's Second Case* was in a 16 year old girl who suddenly suffered from headache and vertigo. There was complete loss of function of the

outer half of each retina. Complete recovery took place in two days.

VI. *Schmidt and Wegner's Case* (7) (1869) was one of brain tumor, presenting ophthalmoscopically the picture of typical albuminuric retinitis. The tumor was the size of a pear, situated in the middle of the left ventricle, and lying loosely upon the large ganglia. The optic thalamus was flattened and atrophied. The growth extended into the third ventricle, involving the *sæptum lucidum*, fornix, and external layer of the corpus callosum. The aqueduct of Sylvius and the fourth ventricle were dilated. The dura was thickened. With such extensive brain disturbance and destruction, the mere fact that the patient was not blind, instead of half blind, would almost place the immediate cause of the hemianopsia in the optic nerve, and not more centrally.

VII. *Daae's Case* (8) (1870) was one terminating in epilepsy, mental deterioration, and death. The nasal field was lost in each eye. Ophthalmoscopically nothing was recorded but alteration in the chorioidal pigment. Five other members of the family were said to have exhibited exactly the same phenomena. This case so far as known must be considered as one of true binasal hemianopsia, due of course, or in all probability, to a double lesion back of the chiasm.

VIII. *Knapp's Well Known Case* (9) (1873) is classical; O. D. showed marked, O. S. slight neuroretinitis. This case is unique, and although it occurred thirty-two years ago, it is interesting to note the correctness of the recorded explanation. A temporary obstruction in the circle of Willis produced an impediment to the blood current, swelling of the arteries, pressure upon the lateral angles of the chiasm, exudation into the arachnoid cavity, and through the intervaginal spaces of the optic nerves, causing neuroretinitis and atrophy. The case is thus perfectly explained, but the beautiful post mortem demonstration of sclerosed vessels pressing upon the sides of the chiasm made almost irresistible the conclusion that this pressure caused of itself the binasal hemianopsia, which we now know is impossible.

IX. *Herschel's Case* (10) (1883) is one which can neither be proved nor disproved. The patient, a woman aged 39 years, fell without warning, was unconscious for a brief period, and speechless for half an hour. Returned to work upon the following day. No sugar, albumin, syphilis, or discoverable constitutional disease. Binasal hemianopsia, which Herschel believed to stand in direct relation to the apopleptic attack. The cause he ascribed to double hæmorrhage in symmetrical portions of the brain (occipital lobes). If this is true, the case was one of genuine binasal hemianopsia. The discs showed atrophic discoloration especially in the temporal halves; there were peripheral color disturbances; the Wernicke pupil was absent. If such a case is possible, it would seem that a unilateral destruction of the uncrossed fibre centre should not be so uncommon in cases of brain hæmorrhage. A double symmetrical hæmorrhage is much more difficult of production than a single hæmorrhage.

X. *Hensen* (11) (1890) records a case of nasal hemianopsia in the right eye, the left eye being entirely blind. The autopsy revealed gummatous exudation surrounding the chiasm. If monocular nasal hemianopsia is to be spoken of, the field of the other eye should not show serious defects. That the chiasm was surrounded by gummatous exudate, and that the fellow eye was blind, are sufficient in themselves to exclude this case as one showing true nasal hemianopsia.

XI. *Lang and Beevor's Case* (12) (1894) is one of tabetic atrophy. Noyes (13) among others speaks of limitation or invasion of the visual field, occurring in glaucoma, optic atrophy, embolism of a retinal vessel, retinitis pigmentosa, etc., but makes a sharp distinction between such limitations and those which he considers under hemianopsia. This case, however, as pointed out below, is probably one with true binasal hemianopsia.

XII. *Eales's Case* (14) (1895). Both discs were "filled in," grayish yellow in color, with blurred margins. Diagnosis, chronic interstitial neuritis. This was the case of which Gowers wrote: "This case suggests a bilateral inflammation of the trunks of the optic nerves in front of the chiasm."

XIII. *Ole Bull's Case* (15) (1895) was a remarkable one. Microscopically the tracts and optic nerves were degenerated, the latter more than the former. In the optic nerves, no fibres were found peripherally. There was of course pure optic atrophy, and the temporal fields were considerably cut.

XIV. *Rakowicz* (15) (1895) in a paper in which he doubted the possibility of nasal hemianopsia, and deprecated the use of the term for cases in which the disease was clearly optic nerve affection, reported a case with typical failure of each nasal field. He avoided the diagnosis of binasal hemianopsia, however, preferring that of optic atrophy. After six weeks the patient was blind.

XV. *Fridenberg's Case* (16) (1896) was a traumatic one. Fridenberg is inclined to think that the lesion causing the hemianopsia was an indirect one, and that the chiasm was gradually compressed upon each side, by callus formation or other newly formed tissue at these points. Basal fracture of the skull is most probable in this case from the nature of the injury, but in view of the anatomical arrangement of the fibres in the optic nerves and chiasm, the callus or newly formed tissue must have pressed upon each nerve separately, rather than upon the lateral chiasm. This case showed optic atrophy, but no neuritis.

XVI. *Eschridge's Case* (17) (1896) was one of brain tumor. Ophthalmoscopically all the findings were of intense acute papillitis. With the two symptoms of binasal hemianopsia and hemianopic pupillary inaction, the diagnosis of tumor at the chiasm was made with considerable confidence. The autopsy revealed a tumor in the left lobe of the cerebellum, and thickening of the pial sheath surrounding the chiasm.

XVII. *Veasey's Case* (18) (1897) shows intraocular inflammation; hæmorrhages, cholesterine, reduced arteries, and cloudy media. He considered his case more like that of Eales than any

other which he reviews, and accepted for it Gow-ers's probable explanation.

XVIII. *Burnett's Case* (19) (1900) was one of nasal hemianopia showing first in one eye, and a few months later becoming double. The exciting cause was a blow on the forehead due to a fall. Each eye was in turn the seat of optic neuritis and papillitis ending in atrophy.

Burnett, after discussing the various theories advanced for the explanation of nasal hemianopia, said of his case: "Whatever else may have preceded, we are forced to consider an optic neuritis as the essential pathological lesion."

Finally XIX. The writer's case, reported in full, is as follows: W. H. S., aged 65 years, male, white, widower, occupation upholsterer, came to the Eye Dispensary of the Presbyterian Hospital in June, 1904. Vision had always been good until eight or nine years previously, when he noticed first that O. S. was failing. The disturbance was described as a central blur, and he felt that O. D. was doing all the work. Did not progress, so far as known until three months before, when he noticed a black film before O. D. There had been a gradual diminution of vision during the previous three months; he could no longer see to work. He was also troubled with ringing in his ears, which Dr. B. H. Potts found to be clearly due to middle ear disturbance.

V. O. D. $\frac{1}{80}$ (eccentric fixation) not improved.

V. O. S. $\frac{1}{30}$ central not improved.

Fixing with O. S., O. D. was divergent. In getting around, the head was turned searchingly in the manner characteristic of loss of the nasal fields. His pupils were equal, the irides rather sluggishly active to light, and the hemianopic pupillary reflex was imperfectly present. Ophthalmoscopically, 0.2, the discs were "filled in" and atrophic. They were "fluffy" in appearance, with margins somewhat blurred. The vessels were small, with irregular contour and changeable calibre. There were a few yellowish spots in the fundus around the disc. All the changes were more pronounced in the right eye.

The left field, that of the better eye, was nasal hemianopic. In its temporal aspect, it was cut concentrically about 20° . Nasally, the field was overshoot about 5° ; the line of demarcation was well defined; the macular region was preserved. The field for red showed a corresponding contraction.

The right field, also nasal hemianopic, showed a large central scotoma. Fixation could be maintained only with a pointer. Temporally, it was much contracted, the greatest contraction being below and out. It was overshoot a few degrees at the centre. In other words, the entire nasal field and most of the temporal field were lost for this eye. Color was not recognized. The hemianopia in each eye was practically absolute.

This patient's general health was subjectively pretty good. He had had some muscular rheumatism, there was no history of syphilis, and no history of lead poisoning. He formerly smoked six to nine cigars daily, and used alcohol moderately, but for the past five months he had not used either tobacco or alcohol. Recent examination of the urine was negative.

He had been carefully examined by Dr. Harvey Shoemaker, and by Dr. William G. Spiller. Dr. Shoemaker reported, August 22, 1904, as follows:

The veins of chest were dilated. Heart: apex beat was neither palpable nor visible. At mitral area was a soft, short systolic murmur, not transmitted; the second sound was impure. At other areas both sounds were impure, but there was no distinct murmur. Heart action quiet, there was some arrhythmia, and second sound was slightly accentuated at pulmonary area. Percussion did not show the heart to be enlarged.

There was marked visible arterial pulsation at wrists, in forearms, and arms, above clavicles, and in neck. All palpable arteries were rather small, but very stiff, with no hard chalky areas in them. Left radial much smaller than right, but the pulses were synchronous. Over upper part of sternum, when the heart action was accelerated,

FIG. 2.—Binasal hemianopic fields in case of neuritic optic atrophy. (Author's case.)

a distinct bruit was heard. Diagnosis: *General Diffuse Cardiac and Arterial Sclerosis*.

Dr. Spiller wrote, August 6, 1904: "I am unable to find any distinct signs of involvement of brain or cord, aside from the disturbance in the visual field."

Medically, this case is one of pronounced diffuse arterial sclerosis; ophthalmologically, it is one of optic atrophy, following or attended in course by a low grade optic neuritis. It forms a very good example of so called binasal hemianopsia, but such a diagnosis would give little information as to the man's true condition.

As to the field defects, the writer believes them to be due to optic-nerve disease. The well marked arterial sclerosis is thought to be a factor in the primary causation, and should opportunity arise, possibly a condition of affairs around the circle of Willis would be found similar to that described by Dr. Knapp.

Of these 19 cases exhibiting nasal hemianopic fields, demonstrable inflammatory disease of the optic nerves was found in 12 cases, or in 63 per cent.

These cases are those of Mandelstamm (2 cases), Schmidt and Wegner, Knapp, Henschen, Eales, Ole Bull, Rakowicz, Eskridge, Veasey, Burnett, and Shoemaker. If with these, Mooren's first case and Fridenberg's case can be included, the percentage of cases of probable optic nerve origin is 73.6. Regarding these two cases, they were traumatic and likely due to fracture.

Fridenberg places callus and other newly formed tissue at each side of the chiasm, but this alone will not explain the binasal hemianopsia in his case. It is probable, therefore, that the direct cause of the hemianopsia is here also in the optic nerves.

The five remaining cases appear to be so far as known cases exhibiting true binasal hemianopsia. Lang and Beevor's case is unfortunately not very fully reported, but from the data at hand, there seems to be no reason why it is not a case with true binasal hemianopsia. The writer believes that only postneuritic atrophy, and atrophy secondary to optic nerve injury or involvement should exclude a true hemianopsia.

The three cases of Graefe, Daae, and Herschel would seem to be of central origin, and likewise show true binasal hemianopsia.

Mooren's second case, which is imperfectly recorded, was transient, and was perhaps psychic.

The destruction of the uncrossed fibres in the optic nerve without serious or immediate destruction of other fibres, can probably be best accounted for by the profusion and arrangement of the *sæpta* or pial processes which enter the nerve, especially in its intracranial portion. Reference to Wilbrand and Sænger's third volume, part I,

page 73, will show how very well developed and numerous many of these pial processes are. Inflammation travelling along these *sæpta*, limited to, commencing in, or more intense in those surrounding the uncrossed fibres, is not at all too unthinkable to have occurred 12 times. It is a well known fact that interstitial inflammation is frequently symmetrical, and therefore it is not so remarkable that it should attack in this manner the optic nerves.

The *sæptum* formation has been shown by Wilbrand and Sænger to be definite, and not haphazard; it is most marked in the intracranial section of the nerve, a piece a little less than 10 mm. in length; and it is almost absent in the tract. The line of demarcation in nasal hemianopic fields is seldom one of perfect bilateral division, whereas in complete homonymous and bitemporal hemianopsia, it should be straight, with of course the well known variations as to the preservation of the macular region. The reason for this is the fact that lesions of the chiasm, or posterior thereto, which produce typical bitemporal or homonymous hemianopsia, destroy all of the fibres, while we can scarcely conceive of pressure lesions, attacking the uncrossed fibres alone anywhere in their course, which will not allow some of them to escape, or involve some of the crossed fibres. Of course, every case of homonymous hemianopsia is nasal hemianopsia for one eye, but the lesion here is totally destructive of both sets of fibres behind the chiasm.

INSECTS; THE ROLE THEY PLAY IN THE TRANSMISSION OF DISEASE.*

By HENRY ALBERT, M. S., M. D.,

IOWA CITY, IA.,

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, IOWA UNIVERSITY COLLEGE OF MEDICINE; DIRECTOR OF THE STATE BOARD OF HEALTH BACTERIOLOGICAL LABORATORY.

That insects have had something to do with the spread of disease has long ago been suspected; the actual demonstration of such was, however, not made until recent years, and the importance of the rôle which they play in the spread of pathogenic microorganisms has yet to be appreciated. For many years Italians have believed that mosquitoes had something to do with malaria, but it was not until 1898 that the relation between the two was absolutely determined. For decades we have chronicled the enormous death rate due to malaria and yellow fever. The lowering and, in many places, the complete abolition of that death rate, during the past five years has been one of the most astonishing accomplishments of scientific medicine.

Let us consider separately and in order the different phases of our subject:

I. The diseases transmitted by insects.

II. The insects responsible for such transmission.

III. How such transmission may occur.

IV. Agents eliminating the insect factor in the transmission of disease.

I. *Diseases Transmitted by Insects.*—There are a number of diseases such as malaria, yellow fever, Texas cattle fever, and possibly also sleeping fever, "spotted fever," relapsing fever, and elephantiasis that are conveyed only through the medium of insects. Others are at times transmitted in this way.

a. *Malaria.*—Although the infective agent of malaria was discovered by Laveran in 1880, and

this disease had long been classed with the communicable diseases, and although it was long ago suspected that the mosquito had something to do with malaria, yet it was not until 1898 that the manner of transmitting the disease was solved. Through the painstaking researches of Ross, Manson, Grassi, and others, we now know that the hæmatozoon malarie requires two hosts for its development; man as the intermediate host for the development of the larval form, and the mosquito, of the genus anopheles, as the definitive host for the development of the adult form. The mosquito forms the only means, so far as we know at present, of transmitting the disease from one individual to another.

b. *Yellow Fever.*—Scarcely less wonderful are the discoveries in connection with yellow fever. Dr. C. J. Finlay, of Havana, in 1881 first advanced the idea that mosquitoes were concerned in the transmission of this disease. In 1900, a committee, consisting of Dr. Reed, Dr. Carroll, Dr. Agramonte, and Dr. Lazear, which had been appointed to investigate the relation existing between the mosquito and yellow fever, reported that the mosquito of the genus *Stegomyia*, served as a host for the parasite of yellow fever and that it was very probable that the disease was propagated only through the bite of this insect. A committee consisting of Parker, Beyer, and Pothier have recently stated that they found a protozoon parasite in the stegomyia, and to have worked out a part of its life history. For this organism they propose the name *Myxococcidium stegomyia* (Marine Hospital Service, Yellow Fever Institute, Bulletin No. 13, March, 1903). It has, as yet, been by no means proved that the bodies found by the last named committee are the real ætiological agents of yellow fever.

c. *Elephantiasis*, due to filaria sanguinis hominis. —The mosquito serves as intermediate host, and transmits the embryo parasite to man through its bite. The parasites probably develop into the adult form in the skin or just beneath it, which probably enter the lymphatics and give birth to broods of embryos that are disseminated in the lymph stream and then enter blood vessels. They occur in the peripheral blood in greatest number when the patient is asleep. When the patient is active they retire to the deeper structures, presumably the lymphatics. By occluding the lymphatics they produce a lymphatic œdema which causes an enlargement, principally of the lower extremities, resulting in the condition known as elephantiasis.

d. *Trypanosomiasis.*—This condition is due to the presence of an animal parasite, trypanosoma, which has an elongated body and a large flagellate caudal extremity. The organisms are found principally

* Read at the sixteenth annual meeting of the Dubuque County (Ia.) Medical Society.

in the blood of the animals affected. There are a number of these parasites, which produce different diseases in different animals (in some cases apparently without effect) and are transmitted from animal to animal, in a few cases at least, by different insects. One of the most important of these diseases in the human being is:

e. Sleeping fever, a very fatal disease which is almost entirely limited to the colored population of Africa. During the past year it has been determined with a great deal of certainty that the specific cause of the disease is a trypanosoma (Castellai, *Brit. Med. Journal*, June 20, 1903), and that it is transmitted by some insect, probably the tsetse fly which also conveys the trypanosoma producing the disease nagana which proves so fatal to many of the domestic horses in Africa. Our common rat is frequently found affected by trypanosoma transmitted by the rat flea. It does not prove fatal, but affords a good opportunity for the laboratory study of this parasite.

f. Relapsing Fever.—Ticktin has examined bed bugs which had filled themselves with blood of men and monkeys suffering from relapsing fever, and found that the blood of these insects contained the specific spirilla for a period varying from eighteen to seventy-seven hours after they had gorged themselves. Some soon become immotile, others remained motile for a long time. Blood, from eight bed bugs which had fed upon an infected monkey, was injected into another monkey which in sixty-four hours developed the disease. The recent researches of Karlinski have caused him to believe that bed bugs play an important part in the transmission of relapsing fever. (Karlinski, *Centralblatt für Bacteriologie*, Bd. XXX, Orig., 1902.)

g. Texas Fever of Cattle.—Theobald Smith has shown that this disease is caused by a very small hematozoon (*Pyrosoma bigeminum*) and is carried from animal to animal through the bite of a tick (*Boophilus bovis*). The adult tick, after gorging itself with the blood of an infected animal, falls to the ground, and in a few days lays her eggs and dies. After several weeks the eggs hatch out, the embryo ticks escape and at the first opportunity attach themselves to cattle, and through their bite infect healthy animals.

h. Typhoid Fever.—During the past few years our attention has frequently been called to the fact that flies play rather an important part in conveying the germs of typhoid fever. Such seems to have been a great factor in the production of the large number of cases of typhoid in the American camps during the Spanish-American war. Flies were very numerous and had free access both to the discharges of typhoid patients and the food of the soldiers.

Smith reported a small epidemic of typhoid at the New Haven county jail, which he attributed to the influence of flies. Twenty-one of the inmates were taken sick. There were several cases of typhoid in the houses near the jail and there was open communication between the jail kitchen and the adjoining yards.

Dr. Alice Hamilton, who made a very careful study of the recent typhoid epidemic in Chicago, believes that flies were concerned in the production of many of the cases (*Jour. of the American Med. Association*, February 28, 1903). Ficker has isolated typhoid bacilli from the bodies of flies caught in a house where eight cases of typhoid occurred (*Arch. f. Hyg., München u. Leipzig*, Bd. XLVI, S. 274). Experimentally, Ficker has shown that typhoid bacilli will live in the bodies of flies for some time, and that flies fed with typhoid bacilli are able to convey the microorganisms to objects with which they come in contact, for as long as twenty-three days after feeding. This emphasizes the great importance of thoroughly disinfecting all discharges from typhoid patients, and of excluding all flies and other insects from dwelling places, especially from the rooms of typhoid fever patients and from the dining rooms of others.

i. Tuberculosis.—The frequency of occurrence of this disease, its almost universal distribution, the manner in which infected material is distributed because of the careless disposition of many consumptives, the great number and disgusting habits of flies, all suggest that the rôle which insects play in the transmission of this disease may not be at all unimportant. Spillmann, Haushalter, and Hoffman have found living and virulent tubercle bacilli in the bodies of flies caught in the rooms of consumptives and also in their faecal specks scraped from the wall or articles of furniture. The greatest care should be taken with tuberculous sputum. It should be collected in spittoons, which contain a disinfecting solution and are always kept well covered.

j. Plague.—It seems very certain that this disease is frequently transmitted by fleas, either,

Fleas that commonly infest the human being, conveying the disease from one individual to another, or,

The rat flea, which leaves the dead rat, an animal very susceptible to plague, as soon as the body becomes cold. These fleas will sometimes bite the human being and so may transmit the disease. Transmission by flies probably also occurs. Nuttall has shown (1897) that flies die of the disease, and Yersin has found the bacilli of this disease in flies infesting his laboratory.

k. Cholera (Asiatic).—There have been a number of epidemics of this disease, the spread of which

cannot be satisfactorily explained except through the agency of flies. Biggs explained the development of a small epidemic of this disease in New York in 1892 on these grounds (*Amer. Jour. of the Med. Sci.*, January, 1893). Macrae performed an interesting experiment by exposing sterilized milk in two apartments of a jail, one of which contained cholera patients and the other did not, but both contained many flies. The milk in the apartment which contained the cholera patients soon became infected with cholera microorganisms, the other did not.

l. Yaws.—The real cause and manner of transmission of this disease is not known. There is, however, good evidence to show that simple sores have been infected with the virus of the disease by certain flies called "yaws flies" which are common in the "yaws" district.

m. Leprosy.—This disease is in some cases probably transmitted by mosquitoes and flies. It is interesting to note that the plague of mosquitoes and an epidemic of leprosy appeared at the same time in the Hawaiian Islands in 1840, at which time mosquitoes were imported, probably from China. Alvarez claims to have discovered bacilli of leprosy in mosquitoes gorged with the blood of lepers. Others have failed to verify his findings.

n. Anthrax.—It is very probable that anthrax is frequently carried from animal to animal and occasionally from animal to man through the bites of flies.

o. Worms.—Tape worms, especially *Tania cucumerina*, a tape worm occasionally found in man but most commonly in the dog, undergoes a part of its development (larval) in the bodies of fleas and dog lice. The swallowing of such insects has caused tape worm infection. Grassi has demonstrated that ordinary flies may ingest the ova of various worms parasitic to man such as the ordinary round worm, pin worm, and tape worm, and later deposit them with their feces. This is, of course, a possible source of infection.

p. Impetigo Contagiosa.—Although it has not yet been well demonstrated clinically that impetigo may be transmitted from the affected to the unaffected by insects, yet there is abundant experimental evidence that this is possible, especially through the medium of lice. Dewevre has been able to transfer the disease in this way in about fifty per cent. of children experimented upon.

q. Purulent Conjunctivitis, such as *Egyptian ophthalmia* and "*Florida sore eyes*."—Flies are attracted by the discharges and in some cases are known to have carried the infection from the affected to the unaffected. There are certain flies (*Hippelates* flies) which are especially prone to

dart into the eyes, nose, etc. These are probably most responsible for carrying the infection.

r. Ordinary Infection.—Paltauf reported a case of fly bite producing erysipelas, meningitis, and death in two days. Joseph gives three cases of septicæmia due to fly bites.

Wounds may be infected by insects, first, directly, by getting in contact with wound; second, indirectly, by carrying infected material to instruments or dressings or to the skin which later through an abrasion may produce an infection.

There are many other diseases or disease conditions that are no doubt occasionally, or frequently, transmitted by insects. Reference to some of these will be made when considering the next subject.

II. *Insects Principally Concerned in the Transmission of Disease.*—*a. Mosquitoes.*—The female of this insect usually lays her eggs on the surface of water and young ones develop only where there is an abundance of moisture. The larvæ remain near the surface and breathe through a respiratory tube near the anal extremity. If this contact with the atmosphere is denied they will soon drown. There are different varieties of mosquitoes concerned in the transmission of different diseases, as follows:

Malaria—*Anopheles*, several varieties, *Anopheles maculipennis*, *Anopheles punctipennis*, etc.

Yellow fever—*Stegomyia fasciata*.

Filariasis—a *Culex* (*Culex pipiens* and *Culex ciliaris*), and possibly also an *anopheles*.

Our common mosquito is also a *Culex* (*Culex pungens*). The recent researches on dengue, by Graham, practically show that this disease is caused by a hæmatozoon which is conveyed by a mosquito. In all of these cases infection is carried by the bite of the mosquito. It is probable that this insect also has something to do with the spread of other disease conditions.

b. Flies.—A number of different flies are concerned in the transmission of different diseases. Probably of greatest importance is our common house fly (*Musca domestica*), which enjoys feasting upon the discharges of animals as much as upon the food of human beings and is very prone to carry infectious material from the one to the other, either mechanically, the infectious material clinging to parts of its body, or by ingestion, and later depositing it with its feces. Or, if the organisms kill the flies, the decomposition of the latter will permit the liberation of the infective material. It is very probable that *Bacillus typhosus* and the tubercle bacillus are frequently spread by flies in one of these three ways. Dr. Alice Hamilton, who made a rather detailed study of the recent mild epidemic of typhoid in Chicago, states that in one instance the dis-

charges from a typhoid patient were put into a privy vault and that a number of flies, caught within the vault, on the fence in the yard, and in the sick room and kitchen of the patient, were examined, and from two of them typhoid bacilli were isolated (*Jour. of the Am. Med. Assn.*, February 28, 1903). Spillman and Haushalter have found virulent tubercle bacilli in the bodies of flies. Madox and Simmond after feeding flies with the spirilla of Asiatic cholera have been able to obtain cultures of this organism from them. Yersin found the bacilli of bubonic plague in flies infesting his laboratory, and Nuttall has shown that flies will die of this disease.

The ordinary fly can travel at the rate of 5.35 metres per second, which would mean ten miles if kept up for one hour. Its powers of producing evil are great and it is not at all improbable that many of our cases of typhoid, both sporadic and epidemic, are due to the agency of flies.

Other flies concerned in the transmission of disease are: The tsetse fly conveying trypanosoma, producing nagana in horses, and sleeping fever in man.

The "yaws fly" connected with the disease, known as "yaws."

The Hippelates fly disseminates a purulent conjunctivitis—"Florida sore eye."

c. *Fleas*.—There are different varieties of these suctorial, wingless insects, which choose different animals as hosts. The one which most commonly affects man is the *Pulex irritans*; the dog and cat flea (*Pulex serraticipes*) may also affect the human being, etc. Fleas are probably the agents frequently conveying trypanosoma infection from rats to rats and plague infection from rats to rats or man and from man to man or rats.

d. *Ticks*.—These insects seem to be capable of conveying a number of diseases:

Texas cattle fever (already described) caused by a small protozoon (*Pyrosoma bigeminum*) which is conveyed by ticks (*Boophilus bovis*).

The carapto disease affecting human beings in Africa seems certainly to be produced by the bite of a tick (*Argas maubata*, Manson, *Brit. Med. Jour.*, September 11, 1903). The infective agent is probably the *Filaria perstans*.

Another "tick fever" of man occurs in Asia, due to the tick *Argas persicus*.

A third probable "tick fever" in man is the so called "spotted fever," a quite fatal although not very common disease which is practically limited to the Bitter Root Valley of the Rocky Mountains. Wilson and Chowning, who discovered the causative agent of the disease, have given to it the name *Pyroplasma hominis*. There is considerable evidence to show that the disease is transmitted to man

by a tick, *Dermacentor reticulatus*. (*Journal of Infectious Diseases*, Vol. 1, No. 1, January 2, 1904, p. 31, and U. S. Public Health Service Bulletin, No. 14, July, 1903). There are still other diseases of horses, sheep, and cattle probably transmitted by ticks.

e. *Bed Bugs* (*Cimex lectularius*).—Nuttall, in 1898, performed a number of experiments permitting bed bugs to bite animals that had died or were dying of anthrax, mouse septicæmia, etc., and then permitted these bugs to bite healthy animals. Results were all negative. During the last few years it has been determined that bed bugs play a very important part in the transmission of relapsing fever (Karlinski, *Centralblatt f. Bact.* Bd. XXXI, Orig., 1902).

f. *Lice*.—Experimentally, Dewevre has conveyed impetigo contagiosa from the affected to the unaffected in a number of cases.

Other insects, such as ants, cockroaches, spiders, etc., also no doubt play some part in spreading infectious diseases.

III. *Insects are capable of spreading disease in a number of different ways:*

a. Pathogenic microorganisms may collect upon the limbs or bodies of insects, and by them be carried to fresh wounds, where they produce direct infection, or to articles of food, thus indirectly infecting the individual consuming such food. The contamination of food is of frequent occurrence, as already stated, and no doubt plays an important part in the transmission of typhoid fever.

b. Insects may ingest disease producing microorganisms with their food and later deposit them with their fæces. Spillman and Haushalter have found living and virulent tubercle bacilli in the fæces of flies that had been fed upon tuberculous sputum.

c. Insects may ingest the germs of disease with their food, be killed by them, and the dead animals may cause infection by,

Falling or dying on articles of food, contaminating the latter.

By decomposition of the body of the dead insect, the liberation of the microorganisms, and their dissemination through the dust. This is especially true of bubonic plague which causes the death of infected flies.

d. Insects may ingest pathogenic germs by biting diseased animals and then transmit them to healthy animals by similar bites. Many examples of this method of infection can be given such as the transmission of anthrax by flies, bubonic plague by fleas, and trypanosomiasis, which in some cases is transmitted by flies, in others by fleas. Certain diseases, such as malaria and yellow fever, are transmitted

only in this way. In such cases, the organisms always have a double life history and undergo one part of it in the body of the insect.

c. Insects may ingest pathogenic microorganisms and transmit them to their offspring, who in turn may inoculate healthy animals. As an example of this method of transmission we have the Texas fever of cattle.

IV. *Agents Eliminating the Insect Factor (a few of the more important insects) in the Spread of Disease:*

a. Destruction of bed bugs, etc.

1. Screen windows to prevent the entrance of bed bugs at night.

2. All crevices obliterated, by papering or painting walls, and using furniture as simple as possible.

3. Infected places may be washed with some disinfecting solution, such as mercuric chloride.

4. Use of pyrethrum, a good palliative.

5. General fumigation, as concerns the destruction of insects. Formaldehyde often fails to kill them. This is a point of considerable importance. Formaldehyde, although superior to sulphur dioxide in the destruction of bacteria, is inferior to the latter when insects are considered. Better than either for the destruction of animal life—large animals as well as insects—is the use of hydrocyanic acid. It has a slight tendency to destroy the color of fabrics and will slightly tarnish polished brass and nickel. The precautions of general fumigation, such as the closing of all crevices, etc., should be observed. For fumigation, Howard advises the addition of one ounce of potassium cyanide (98 per cent.) to a solution containing one ounce of commercial sulphuric acid diluted, with two ounces of water to every 1,000 cubic feet of room space. After twenty-four hours, the room should be thoroughly aired (preferably about twenty-four hours) before it is again occupied.

Although affording a very efficient means for the destruction of animal life, such as bed bugs, cockroaches, clothes moths, ants, flies, etc., as well as rats and mice, the use of hydrocyanic acid is both expensive and dangerous and it should be used only when the greatest precautions are taken.

b. *Flies*.—Although we may greatly lessen the number of flies by rendering the breeding places (usually manure) inaccessible to flies, or when accessible, by the occasional addition of chlorinated lime to destroy the larvæ as recommended by Howard, yet the extermination of these pests will not be accomplished for some time at least. We may do something, however, to free ourselves from the dangers that lurk about these creatures. In the first place we may deny their access to special sources of infection

by such means as the thorough disinfection of the bowel and bladder discharges of typhoid fever patients. In the second place we can prevent them from gaining entrance into our dwelling places and from contaminating our food, by the use of screens and fly nets. And, lastly, their number may be decreased by the use of sticking paper, poison, etc., or by entirely eradicating them from a room by fumigation.

c. *Destruction of Mosquitoes*.—It is rather hard to destroy large numbers of the adult forms except by fumigation, but since the larval forms are more accessible, it is to them that the axe is placed. This may be done by:

1. Removal of their breeding places by draining swamps and other small bodies of standing water, and by preventing the accumulation of water in cans, pails, barrels, etc.

2. Lakes, watering troughs, etc., may be stocked with different varieties of fish, which will swallow the larvæ before they develop into adult forms.

3. The surface of water which cannot be drained may be covered by a film of coal oil, petroleum, or kerosene, about one ounce to every fifteen square feet. This kills the adult female when she attempts to deposit her eggs, it prevents the development of eggs, and kills the larval forms, since it is impossible for them to breathe. This oil does not injure the fish below.

If it is impossible to destroy all the mosquitoes, we may further protect ourselves by:

4. Screening doors and windows, and thus preventing the entrance of mosquitoes into houses, especially those containing patients with malaria, yellow fever, or filariasis.

5. Pyrethrum (Persian powder) may be blown about the room or burned. This has no effect on the human being, but stupefies the insects so that they may be collected and destroyed.

6. To keep mosquitoes from the body a number of substances, such as the essential oil of lavender, pennyroyal, peppermint, eucalyptus, camphor, etc., have been advised, but they are all volatile and exert their good influence for but a short time. Howard mentions the use of the following formula: Castor oil, one ounce; alcohol, one ounce, and oil of lavender, one drachm. The use of an ointment of petrolatum which has been impregnated with peppermint and eucalyptus is also useful and convenient. As an application for mosquito bites, Howard mentions the use of alcohol, ammonia, or glycerin, singly or combined.

This brief review of the subject under consideration gives us at least a glimpse of the important rôle played by insects in the transmission of disease. That chapter in preventive medicine which

will refer to the zeal and energy with which the clinical observations and laboratory experiments in such diseases as malaria and yellow fever were conducted; which will relate the sacrifice of a Lazear's life, a consequence of devotion to science; and which will tell us of the enormous saving in human life and suffering that has resulted from researches along these lines, during the last five years, will be one of the brightest that an historian will have occasion to record.

GONORRHŒA IN ITS FEMALE PELVIC RELATIONS.*

By ELY VAN DE WARKER, M. D.,

SYRACUSE, N. Y.

Dating from Noeggarath's book, *Die latente Gonorrhæ in weiblichen Geschlecht*, in 1872, gonorrhœa has become one of the urgent questions of the day. It may be said to belong to the trilogy of diseases that press urgently for solution. I would name these three diseases in the order in which they appear to me most important; gonorrhœa, tuberculosis, and syphilis. I place gonorrhœa before tuberculosis, not because it is less destructive to life than the latter, but because it is potentially more dangerous to society in its power to impair fertility and permanently infringe upon usefulness. An opinion well held is worth two facts to an average mind; almost equally groundless is a fact born before its time. It required time to change the attitude of surgeons toward the importance of gonorrhœal infection of women. It becomes the history of a new idea rather than the history of a fact. Gonorrhœa as a sexual disease was a duly regarded fact older than our civilization, but that a woman once infected always remained the nidus of a dangerous pus producing germ was too revolutionary to be regarded seriously. I remember well the effect that Dr. Noeggarath's revolutionary theory produced in my own mind, but I had the advantage of an intimacy with Dr. Noeggarath, and had learned to place the utmost reliance upon his sincerity of purpose and the firm logical qualities of his mind. To me the stage of incredulity was short, and I was among the first in this country to give my allegiance to his views.

As becomes a man who holds to bold and original ideas Dr. Noeggarath was very tenacious of his opinions. The writer remembers an invitation to luncheon by Dr. Noeggarath after the reading of his paper before the American Gynecological Society, where it was received with

strenuous opposition. He could talk of nothing else than the subject of his paper, and naturally felt sore over the hostile tone which the subject evoked. I could offer no opposition to his theory, although I must admit that I was skeptical, but I did venture an objection to his choice of a word. I believed, then, and I have not changed my opinion since, that unnecessary opposition was provoked by the term "latent" rather than by his theory, supported as it was at that time by a rather scant array of facts; this opposition was one of opinion only as at that time bacteriology could not afford the demonstration of positive proof. Latent was evidently not the word that Dr. Noeggarath wanted. Webster gives two definitions; the colloquial and the scientific with meanings widely different. In the latter as a botanical term we have latent buds, those that have passed the period of expansion without development. Latent heat in physics, that quantity of heat which disappears or becomes concealed in a body while undergoing some changes other than a rise of temperature as evaporation or expansion. In medicine we have another use, and here the author made his mistake, as a disease may be latent, or have a period of latency, before its development, as in the exanthemata in which after exposure the health is not affected until the prodromes appear. Crabb in English Synonymes gives the revealing word. What is secret is known to some one. The Latin word latens means hidden, lying secret, or concealed. The German word is in its Latin form. I have gone into these definitions to show how misleading Dr. Noeggarath's choice of a word was. Nothing latent in relation to gonorrhœa was described in his German work or in his paper in the gynecological transactions. Surely nothing is latent about a disease that is daily, for prolonged periods of years, insidiously undermining health or destroying life. It gains no meaning of latency, because it has the faculty of pathological longevity. Neither can the term be applied to a disease that produces no other evidence of its existence than an incurable sterility.

It is not worth the trouble to seek a better term. The words latent gonorrhœa have passed into medical literature, and no matter what the word may be, the views of Dr. Noeggarath have been confirmed over and over again as time has passed. He has done more than any one to place the disease among the most dangerous of those that afflict humanity.

While we are all familiar with the clinical picture so graphically drawn by Dr. Noeggarath with the inspiration of the enthusiast, yet it is

* Part of a "symposium" on gonorrhœa held by the Syracuse Academy of Medicine.

well worth the time to refer at least to one of his cases, as the paper is contained in a volume long out of print and inaccessible to the most of you. I will cite but one case.

Mr. M., formerly a commercial traveler for a large manufacturing firm in Europe acquired a gonorrhœa. The treatment recommended by a renowned specialist was at once carefully followed and the affection was cured in two months. Two years later this gentleman married a healthy, robust young lady from B., a village in the province of Westphalia, Germany. Three months later the woman began to complain of backache and general malaise; it became difficult for her to supervise her household affairs; the usual promenade instead of being a pleasure became fatiguing. Menstruation, which appeared hitherto without giving any preparatory notice, was now connected with backache, more profuse than usual, and followed by a white discharge. By and by the desire to urinate became more frequent, and was occasionally accompanied with a burning at the meatus. The white discharge gradually extended from one period to the other. About eight weeks later a pain was felt in the left side of the abdomen, which suddenly increased upon any unusually severe exertion, to such an extent that the patient had to take to her bed. At the same time the dysuria was considerably increased, the discharge became profuse and of a greenish yellow color like pus. The physician attending her recognized an attack of perimetritis. A year after this she consulted me for sterility. I found her suffering from general weakness, backache, pain in the left side, increased before the now scanty menstruation and a mucopurulent discharge. On examination the uterus was found in right lateroversion and ante-flexed; the left vaginal roof or parts above, hardened and contracted; the uterus soft, succulent, very tender on being pushed into its normal position, with great tenderness of posterior cul-de-sac. The neck was of a high color, the os surrounded by a thin rim of eroded tissue, discharging a tenacious yellow mucus. Both outlets of Cowper's glands were eroded to some distance and painful to the touch. Dr. Noeggerath briefly commented upon this. He said: "This combination and development of symptoms, physical as well as rational, you will never find in women who are married to husbands who have not exposed themselves to the danger of venereal affections. I say, advisedly never! And if any one has a right to speak thus positively, I claim this privilege." He further stated that this patient had never been infected in the accepted meaning of the word, but she gradually developed a condition which we usually observe as the result of an acute attack of gonorrhœa. This may have been true in 1872, but it is not held as true now, as we recognize these cases as positive and active, not latent infections.

I have now under observation a case so nearly identical with this one, but connected with such positive proof of the absolute chastity of the

young lady previous to marriage that the case is unique and worthy of a brief study.

Mrs. G. L., of Utica, brought her daughter to me many years ago. She was a well formed girl about thirteen years old. The abdomen was distended by a mass extending above the umbilicus. An inspection showed a bulging of an imperforate hymen. Under careful antiseptic preparation the menstrual accumulation was drawn off through a trocar. The hymen was then divided by a crucial incision and the mucous membrane covering both surfaces of the obstructing hymen stitched together to insure against cicatricial contraction. This opening proved ample to drain away the menstrual secretion. In this condition she was allowed to remain until a little past the twentieth year when she became engaged to marry. We had always understood that an additional operation would be necessary to prepare her for marital duties. The hymenal remnants were dissected away, the edges of the mucous membrane brought together by sutures, and in a week or so the patient returned home with the lumen of the vulva restored to its normal proportion. The hymen, which was removed entire, was a resistant cicatrix with a central opening, large enough to meet its physiological function, but through which the tip of the little finger could not be forced. Bimanual palpation proved the pelvis to be free from any mass, indurations, or adhesions, with the uterus in a typically normal position. Inspection showed the vaginal portion to be free from any erosions and the cervical canal without any catarrhal discharge.

Here we had a young and healthy girl, free from any specific infection and demonstratively so from absolute necessity. In about a month she was married. It is not prudent to delve any deeper into family history. In two months after marriage, just preceding a menstrual period, she was attacked by a sudden chill, followed by a mild febrile reaction and the rapid development of a mass in the right iliac fossa, attended by excruciating pain. The tenderness over the mass was excessive, gradually shading off over the abdomen. On palpation the uterus was found to be fixed, the fundus crowded over to the left. Any attempt to push the uterus into its normal axis was too painful to be persisted in. In about a month the acute symptoms had subsided. The mass to the right had quite disappeared and the uterus was nearly restored to its normal mobility. She then came under my personal care and by appropriate treatment the rapid cure was confirmed and she returned home under engagement to return and resume treatment in a month. During this interval she saw her husband a couple of times. Agreeably to her promise she returned and I was surprised to find that the pelvic tenderness had slightly returned and there was evidently a lessened uterine mobility.

The husband confessed to having contracted a gonorrhœa about seven years previous to his marriage. At long intervals after that he had observed a slight urethral catarrh, generally without tenderness, but sometimes with a little itch-

ing and redness at the meatus. This urethral catarrh would recur at wide and irregular intervals. He stated that he had even gone a year without noticing any discharge, but quite often he had observed it three or four times a year. Just before the pelvic outbreak in the wife he had noticed a discharge of about a week's duration.

It does not appear possible that this attack from which the wife suffered could be traced to any cause other than that of an acute gonorrhœal infection. It was acute, so far as it related to the wife; it was chronic concerning the husband. In his case it is gonorrhœa, not in a potential form, or latent, but active, with passive and exacerbated intervals. It is doubtful if he ever recovers from it, and it is more than doubtful if the wife ever becomes immune to the perennial fountain of germs furnished by the husband.

Clinically speaking, we have been safe within the limit of our pathological purview; biologically we have not. Concerning this, investigations have been carried out upon the conjunctiva of the newly born. For these we are principally indebted to Bumm. The urethral mucous membrane is not situated favorably for the investigation of the immediate effect of the gonococci upon the tissue. His observations show that the microorganism possesses but a limited range of tissue penetration. The gonococci penetrate only the most superficial sheaths of the subepithelial layer. Their power to penetrate lymph vessels and capillary blood vessels is denied, and against this denial we have only the solitary case of Bockhart. Taking the invasion of the conjunctiva in ophthalmic blennorrhœa neonatorum as a type, we can trace the "reaction of the tissues in the acute stage corresponds to the violence of the onset and the rapidity with which the microorganism is developed; and in the later stages, when the tissues have become protected by the development of epithelium due to the reaction of the tissues, and the gonococcus disappears, the remaining phenomena of the disease are just those which may be produced by any chronic irritation" (Sinclair).

This may explain the life history of the gonococcus, but it does not explain the clinical phenomena offered by the genitals of men and women when once exposed to the attack of the organism. If one were asked to define the most characteristic trait of a gonorrhœal infection we would be obliged to say that it was its tendency to persist and recur. If what the biologists say of the pure culture of the gonococcus germ when placed upon favorable soil is true, we must search further to find the true explanation of the clinical findings after an acute infection. Bumm offers the most reasonable explanation of the

gonorrhœal mystery. This is the theory of mixed infections. These are consecutive and not accidental. These infections are attended by constancy of association, and point to the certainty that when one germ has found lodgment, another form of germ invasion will find the way prepared for it and will follow as a matter of pathological certainty.

The gonococcus, by its invasion of the genital tract of women, causes such changes in its mucous sublayer that other fungi which are usually present as non-pathogenic become morbidly active, and then assume an activity distinct in life history from the gonococci. As an illustration, take the vulvovaginal glands. These are very frequently the seat of gonorrhœa in women. The stage is an active purulent one, followed by a mucous discharge of indefinite chronicity. When, however, such a gland is invaded by a pyogenous microorganism, an intensely purulent action at once takes place. When it is removed and examined, it is found that the pus inside the gland is caused by pyogenous staphylococci which have destroyed the gonorrhœal germs, have penetrated into the gland, and continued their invasion into the connective tissue surrounding it. Watson Chyne, in the *British Medical Journal*, gives about the same conclusion in suppurative adenitis in the inguinal gland as the result of a mixed infection.

In the genital tract, inflammatory processes, after gonorrhœal germs have invaded the cervical and uterine cavities, extend to the pelvic connective tissue and the peritonæum. The germs of gonorrhœa do not directly invade the lymph tracts and the connective tissue about the uterus and cause inflammation and exudation. "The territory of the gonococcus is fortunately limited to the superficial layers of the mucous membrane. Gonorrhœal para and parametritis cannot be explained by the action of the gonococci; there must, therefore, be another agent, which under the influence of the infection of the mucous membrane, passes into the parametric tissues and there causes disturbance. It is not very common for that exudation to break down into pus; if it does so the occurrence is due to a mixed infection" (Sinclair). Senn in his *Surgical Bacteriology* also quotes the foregoing extract approvingly. Bumm reaches the conclusion that "purulent parametritis with gonorrhœa of the cervix is due to a mixed infection with pyogenous bacteria; it is the analogue of the acute gonorrhœal bubo in the male, which likewise owes its origin to pyogenous germs."

Sinclair says, that the further the specific in-

fection moves upward from the cervix, the fewer are the admixtures with the associated pus producing germs. In infected uterine secretions few other bacteria are found, and they are scarcely ever found in the tube, as it appears that the associated germs are either left behind, or are exterminated. In the tubes, therefore, the activity of the specific germ is expended with the least possible adulteration with other pus producing agents. Here they cause inflammation of the mucous membrane, but do not invade the enveloping connective tissue. The gonorrhœal pus escapes into the peritonæum, where the process terminates in circumscribed adhesive inflammation which encloses the pus. A purulent pelvic cellulitis sac bursting into the abdominal cavity causes general peritonitis, "because it contains pyogenous streptococci which rapidly multiply in serous cavities. Specific pus cannot do this; its microbes do not find in the peritonæum conditions favorable to their increase. The pus, therefore, acts as an aseptic body, becomes incapsulated, and is finally absorbed" (Sinclair, Bumm).

If the gonorrhœal germ has such a limited power of tissue penetration; if its natural habitat is the mucous membrane; and if when it migrates into, or upon other tissues, its pathogenic activity is limited or destroyed, it has left part of the gonorrhœal mystery unsolved. In suppurative arthritis, in remote abscesses, and even in the blood current the gonorrhœal diplococcus has been found. How did it get there? May it not have been carried along in the wake of its associated germs like a shark with its attendant pilot fish? Here is a wide field yet unexplored now occupied by contending factions of bacteriologists. The surgeon, working at the bedside instead of in the laboratory, must in the absence of any authoritative guide select for himself such facts that the bacteriologist places before him as will most rationally make clear the clinical difficulties he may encounter.

I have always regarded the perimetritic abscess as of gonorrhœal origin. We cannot dispute Bumm's facts which are adhered to by such men as Senn and Sinclair. Here is a form of abscess that develops with alarming rapidity, becomes quickly circumscribed, and, in the old days before abdominal or vaginal section, I have seen scores of them self terminated by absorption. These are the pelvic conditions that may properly be called relapsing. Even after uterine tenderness and mobility are restored, from causes so slight as to escape notice, we may find a return of the adhesions, the old uterine lateral dis-

placement, and the lateral pelvic mass. It is different in the parametritic, the cellulitic abscess, or the abscess of the fossa. These are the ones that persist until they find an outlet to the surface, but when once evacuated and healed they never return. I have had the pus from this type of abscess examined and found free from gonorrhœal germs, except in two instances, in which organisms of a doubtful character were found. Abscesses of this type may supervene upon gonorrhœa. The lesion of the mucous membrane may offer a convenient channel for the mixed pyogenic organisms to invade the connective tissue structure of the pelvis. The disposition of this type of abscess to remain cured after evacuation, in contrast to the tendency of the perimetritic to recur, may be due to the fact that the tube offers such a lasting nidus for the specific germs that they may leak again and again into the pelvic cavity and cause the renewal of the inflammation.

The uterine displacements due to these pelvic conditions are quite uniform. They are lateral and directed away from the affected side. Strong anteversions, with the cervix high in the sacrum, and caused by posterior adhesion, are also quite frequent.

Cystitis is another form of mixed infection invited by an attack of gonorrhœa. Sinclair states that the specific cocci do not attack the bladder epithelium as they do that of the urethra and vagina and cause suppuration, but that other and associated germs produce this result.

In conclusion I believe I am within the limit of well established facts when I say that the germ of gonorrhœa is the most active morbid agent known. It possesses the malevolent traits of not only by itself causing destructive processes, but it has the power to develop into malignant activity germs, otherwise non-pathogenic, far more active in their power to inflict damage than the specific germ itself. If we measure this activity by the lasting disabilities both functional and physical that are caused, we see in this almost universally distributed disease a serious menace to the fertility and prosperity of the nation. One of the saddest conditions of all is the fact that it usually claims an innocent victim—a woman—who in her own person develops the diseased conditions that threaten the prosperity and well being of the community.

Accident to a Newark Physician.—Dr. Augustus V. Wendel, of Newark, was thrown from his sleigh on January 28th and sustained a fractured leg.

THE PRACTICAL VALUE OF LITTEN'S "DIAPHRAGM PHENOMENON" IN DIAGNOSIS.*

By WILLIAM N. BERKELEY, A. B., M. D.,

NEW YORK,

ASSISTANT IN MEDICINE, UNIVERSITY-BELLEVUE MEDICAL COL-
LEGE; ATTENDING PHYSICIAN, GOOD SAMARITAN
DISPENSARY.

In respect of terms used in designating this phenomenon, Litten's sign, Litten's phenomenon, Litten's diaphragm phenomenon, Litten's "shadow," and the "diaphragm shadow" have been employed. There is no special objection to any of these words except "shadow," which appears to be a distinct misnomer of the physiological process involved. As a good term, both brief and specific, I would venture to suggest *phrenic wave*, but the older expressions have probably come to stay.

The sign may be described as the visible descending and ascending wave associated with the respiratory movements of the diaphragm in the lower zone of the thorax. The excursion in normal adults is usually between 2 and 5 inches. The exact physiology has not been fully worked out. It seems reasonable that, for the rising wave at least, some function must be assigned to vacuum traction by the pulmonary margins, as well as to the diaphragm itself. It is not my present purpose, however, to study minutely the physiology of the sign.

As regards the history and literature of the sign, it appears to have been noticed some time ago as an occasional curiosity by Gerhardt (1), but M. Litten (2), in 1892, first called attention to its clinical value. Subsequent papers by him (3), notices in the textbooks of Cabot (4) and Sahli (5), a paper by A. Abrams (6), and a recent exhaustive study by Puglisi (7), have entirely confirmed and somewhat amplified Litten's views and have given the sign a permanent place. It is now beginning to be mentioned by lecturers in the colleges, and the oncoming generation of medical graduates who pass under my notice as students appear usually to have heard of it, though with a rather vague notion of what useful information it may be expected to convey.

To elicit the sign, Litten instructs (*l. c.*) that the patient should be on his back, knees toward a good daylight, head flat, lower limbs extended, and should be directed to take a deep breath. He mentions also that by lying on the belly the patient can sometimes breathe deeply enough to

show the wave in the lower posterior zone of the thorax. Later observers found a good artificial light (lamp, candle, electric bulb) as effective or nearly as effective as daylight, and that in favorable cases the wave may be noticed when the patient is standing or sitting as well as when lying down. Abrams (*l. c.*) states (for reasons difficult to understand) that coloring the thoracic wall yellow with alcoholic solution of gamboge or other convenient stain, accentuates the shadow; also that pinching up and tightening the skin over the area where the wave is expected to appear will do the same. The former expedient I have not tried; the latter is perhaps useful in so far as it startles the patient and makes his diaphragm contract more actively. To these suggestions I may add as the result of personal experience that the shadow is sometimes (not always) much plainer if the patient's head and knees be *not flat*, but raised as in palpating the abdomen, for the simple reason that the thoracic tissues, being thus relaxed to the greatest possible extent, yield more completely to the traction of the diaphragm. In fat or muscular subjects the gain from this suggestion is specially great. Cross lights only are objectionable; a straight light may fall in any direction if strong enough.

The percentage of occurrence of the sign in presumably healthy subjects more than four years old is variously given. Litten thinks it always present; Puglisi, in several hundred presumably normal cases, found it in 86 per cent. A damaging factor in such statistics is the fact that old pleuritic adhesions are unexpectedly present in numbers of patients presumed to be normal; this would probably raise the percentage of occurrence in health to 90 + per cent.

As to limitations in health, the patient must of course be intelligent, at least to the extent of knowing how to take a deep diaphragmatic breath. Thoracic breathing is often unaccompanied by contraction of the diaphragm, but if the inspiratory effort is great enough, the diaphragm will finally descend. When the patient is quite unable to move his diaphragm voluntarily, one may lay the fingers firmly along the lower edge of the liver on either side, make firm pressure upwards, and thus quite often *surprise* the diaphragm into a contraction.

Unless the sign is evident in tidal breathing, it will of course be absent in infants. As regards later ages, I have been able to get the sign as early as the third or fourth year in docile children, and in small babies it is quite often noticeable when the child is crying. From five years up it is easy to find, and continues to be readily

* Read before the Society of Internal Medicine, New York.

perceptible until the cartilages in advancing years begin to lose their elasticity. When calcification of the cartilages has distinctly begun, the wave is broken at the crossing of each rib and shows only in the soft tissues.

Narrow costal interspaces are unfavorable to a good wave, and if these are combined with calcified cartilages the wave will be recognized only with great difficulty.

It seems hardly needful to add that no one ought to confuse with a true wave the stationary traction on the ribs made by the insertions of the diaphragm, though Sahli gives much space to the distinction.

Pathologically, or at least abnormally, the sign is, like fremitus, (1) *increased*, (2) *diminished*, or (3) *absent*, always noting of course that these distinctions are relative.

(1) *Exaggeration* may be soon disposed of. It may be bilateral or unilateral. The former is noted in persons of large lung capacity (*pulmo excessivus* of German writers) and in some small chested persons who have a habit of specially marked diaphragmatic breathing. Unilateral exaggeration is, as a rule, a sign of diminished function of the opposite lung.

(2) *Diminution*.—This is to be expected constantly on both sides in asthma and emphysema; on one or both sides in pleurodynia and intercostal neuralgia, in early tuberculosis, in fibroid disease of the lung when not accompanied by extensive adhesive pleurisy; in hypertrophy of the heart or pericardial effusion, and in tumors of the mediastinum. Irregular pleural adhesions will also break the wave in various ways. In asthma and emphysema we may note that the wave is not only low along the thoracic outlet, but near the middle line in front will even run down over the costal margins a little way upon the epigastrium.

The most important condition denoted by unilateral diminution of the wave is early tuberculosis. This disease usually starts unilaterally, or is at least more marked in one apex, the other lung enlarging somewhat in compensation. I have seen but one early case of apical phthisis in the last four years (tubercle bacillus in the sputum) in which the wave on the affected side was not markedly less than on the other.

Bronchitis is also said (Puglisi) to lessen the excursion, though this statement I am not able to confirm.

(3) *Absence*.—The wave will usually be absent on the diseased side in advanced consolidation of the lung from whatever cause, in pleurisy with any kind of fluid effusion, in pneumothorax,

and in such rare conditions as spasm or paralysis of the diaphragm. Extensive adhesions abolish the wave, partial or disseminated adhesions modify without inhibiting it. Acute fibrinous pleurisy also inhibits the wave as a rule, but probably only because of the pain produced by taking a deep breath.

It would take needless time to mention the obvious abdominal causes which mechanically inhibit the wave; dropsy, tumors (specially ovarian tumors), and pregnancy after the seventh month, may be specially mentioned. Subdiaphragmatic abscess has been stated by Litten to leave the wave unaffected, thus giving a differential point in comparison with empyema.

My practical conclusions are as follows:

(1) To students in physiology, the phrenic wave is useful as a demonstration of the respiratory movements of the diaphragm.

(2) When unbroken and over 3 inches in extent on both sides, it is a good indication of healthy lungs, and should be incorporated as such into life insurance examinations.

(3) As an easy and practical substitute in many cases for the expensive and laborious x ray examination of the movements of the diaphragm, when such an examination is desired (Cabot).

(4) When diminished markedly on both sides, low down in the thorax, and more marked behind than in front, it is an excellent sign of asthma and emphysema.

(5) When absent or nearly absent on one side only, it is a useful confirmatory sign of a variety of conditions which may be suspected from other signs, particularly pleurisy and early tuberculosis.

(6) When absent on both sides no conclusion of any kind is really justifiable, unless the patient has been previously known to have had good waves.

REPORT OF A CASE OF CEREBROSPINAL MENINGITIS, LUMBAR PUNCTURE, PURULENT CEREBROSPINAL FLUID, PERFECT RE- COVERY.*

By SIGMUND A. AGATSTON, M. D.,

NEW YORK.

CASE.—The patient, F. A., was a boy 16 years of age. With the exception of having suffered from some of the diseases of childhood, he always enjoyed good health. Five weeks previous to his coming under my observation he was taken with chill, fever, headache, projectile vomiting, extreme drowsiness, and mild delirium. The drowsy condition persisted for twenty-four hours. After that, although he was up and around, the patient did not regain his normal state, but remained languid both mentally and physically. His appetite was poor; he complained of headache and a feeling of lassitude, and was described as having lost all ambition. He received treatment for malaria from the physician who attended him at the time. On May 28th he had been active up to a late hour. On May 29th, at 10 a. m., he complained of not feeling well, lay down, and fell into a state of stupor. He could be aroused only with difficulty, and answered questions incoherently. His pupils were normal and reacted slowly to light. Scattered over the trunk and both upper and lower extremities, there was a purpuric eruption. Pulse was 100, extremely feeble, and scarcely felt at the wrist; respiration normal; temperature, 104°. At 11 a. m., he had a severe chill, which lasted fifteen minutes. During this chill he had an attack of vomiting, which was of projectile character. He vomited all food and medication during the first twenty-four hours. At 5.30 p. m., pulse was 86 and temperature 103.6°; and at 8.30 p. m., pulse was 82, temperature 103°. The patient remained in a state of stupor all day, and toward night became very restless, incessantly tossing about, and moaning. On May 30th, at 2 a. m., pulse was 76, temperature 101.6°; and at 5 a. m., pulse 77, temperature 99.8°. The pulse was very irregular, intermittent, and feeble. Restlessness, and alternating delirium and stupor persisted all night. At 8 a. m., pulse was 88, temperature 99.6°; and at 11 a. m. pulse was 120, and temperature 100°. The patient developed orthotonos and showed the Kernig sign. Neither the Babinski symptom, nor that of McEwen was present. Toward evening of the second day, the pulse rose to 130, and the temperature to 101.4°. During the second night, the pulse became extremely feeble, scarcely felt, and ranging between 140 and 160. On May 31st, the third day of the disease, the condition remained about the same, the pulse improving somewhat after copious stimulation, and the temperature remaining at 101.4°, showing no remission. The blood count was taken, and the leucocytes were found to number 35,000 principally of the polynuclear type. Next in order was a lumbar puncture made by

Dr. Henry Heiman, whom I asked to see the case. Thirty-five c.c. of cerebrospinal fluid were drawn off. The fluid came out slowly by drops, and was thick with pus. Cultures of this, made by Dr. Heiman, showed a pure growth of the meningococci of Weichselbaum. At 7 p. m., two hours after the puncture, the pulse was 160 and the temperature 103.6°; and at midnight the temperature was 104.2°, showing considerable rise. The pulse was very rapid and of extremely poor quality all night. There were alternating delirium and stupor, and involuntary urination. Toward morning, the patient became quiet and his condition improved. The temperature was 101°; the pulse was of better quality, ranging between 120 and 130. The Kernig sign disappeared, and the back became less rigid. The patient was in a condition of mild stupor from which he could easily be aroused and made to answer questions. His condition continued to improve. On June 2nd, however, the patient developed a lobar pneumonia, and on June 7th an arthritis in one knee joint. These complications ran a regular course, the fever defervescing on June 9th. The symptoms from cerebral pressure never returned. The patient was convalescent by June 14th, and by the end of the month he was allowed to go out. His recovery was perfect, without any sequel whatsoever.

One of the interesting features of this case is, that according to the history, the patient either had a mild attack which was followed by a relapse five weeks later, or, as he did not recover entirely after what seemed a primary attack, he had what might perhaps be called a long prodromal period. This, while common in tuberculous meningitis, is unusual in the epidemic form, which most frequently has a sudden onset. The case may probably be placed in the same category with the atypical form described by Delafield, in which the symptoms are mild at first, resembling a walking typhoid or malaria, and after two weeks or more, the patient passes into a state of alternating delirium and stupor. These cases have been found by him to have a very high mortality.

The point of great interest, however, is, that the presence of a thickly purulent cerebrospinal fluid did not prevent an absolute recovery. According to statistics, the majority of the cases that recover are those with slightly turbid cerebrospinal fluid. When the fluid is markedly purulent, a recovery, and especially a perfect one, seems to be rare in consequence of the coexistent pathological conditions and the intensity of the toxæmia. Koplik states in his recent report, that he has been unable to save any of these cases. Nammack reports a case with purulent cerebrospinal fluid which recovered, seemingly, after treatment with ten per cent. lysol injection into

the spinal canal, the only sequel being a persistent sciatica.

50 WEST ONE HUNDRED AND TWELFTH STREET.

DRY GANGRENE FOLLOWING THE APPLICATION OF CARBOLIC ACID DRESSING COVERED WITH OILED SILK.

By VERTNER KENERSON, A. M., M. D.,

BUFFALO.

On October 16, 1904, an application of 1 to 50 carbolic acid on a light dressing was ordered for four hours for the purpose of aborting a felon, with instructions to remove the dressing as soon as the skin was blanched. The dressing was ordered about noon, and at five o'clock the finger was reported as blanched, but "prickling some." The solution was ordered to be diluted to 1 to 100.

At about this time the finger was seen by a friend who noticing the wet dressing offered to supply some oiled silk to keep the dressing from wetting the clothes. This was applied without consulting the doctor, and was left in situ over night. On October 17th the finger seemed numb, and although the finger was blanched, the dressing was still continued, and was still covered with the oiled silk. The patient telephoned that the finger felt "funny," and was told to come to the office at once. He came, and it was noticed that the finger was blanched and numb in sensation, but could feel pressure. The oiled silk was at once removed and a simple dry dressing put on, the nail of the finger having good color at this time. At six o'clock on October 17th the nail was black, the skin was dusky all over the part of the finger that had been covered with oiled silk, but the proximal joint was not so dusky as the tip and the second joint.

Return circulation was cared for as much as possible, by putting the finger in a warm poultice, and the circulation did return in the proximal joint to such an extent that the finger was saved to a point three fourths of an inch from the place where the string was tied about the oiled silk.

The circulation did not return at all in the distal joint, and dry gangrene followed, the skin all coming off and separation of the muscles occurring at the end of the eighth day. Amputation was performed October 27th, at the tip of the first phalangeal bone, cutting away the articular cartilage after disarticulating.

Carbolic acid is the best penetrating disinfectant in those infections that do not proceed from an open wound, as it has real penetrating power through unbroken skin, but it should never be covered with any material that will prevent evaporation, and should be applied only with a light dressing.

Gift to the Postgraduate School.—An anonymous gift of \$5,000 was made to this institution on January 27th.

THE NAUSEA OF SEASICKNESS.

By CHARLES W. HOGG,

S. S. *Arabic*, WHITE STAR LINE,

STATEROOM STEWARD.

After twenty-one years of practical experience in dealing with cases of seasickness, it gives me much pleasure to submit a few simple rules which the voyager will find of inestimable value both in shortening the duration of the attack and even in completely avoiding the malady.

The treatment should be begun at least forty-eight hours before sailing. The alimentary tract should be thoroughly cleansed by the use of suitable aperients, and the diet thereafter consist of very moderate quantities of plain and nutritious food.

Owing to the number of farewell dinners which the traveler frequently attends, this preparatory abstemiousness is seldom observed. This fact, together with the encouragement which the passenger receives from his belief that he is going to be seasick, accounts for a large proportion of the illnesses.

During the first twenty-four hours on shipboard the food should be simple, sparing in quantity, and liquids and fruits should be avoided.

Should a feeling of nausea develop, the subject should at once go to his berth and be perfectly still, seeing no one except those who are in attendance upon him, and talking to them as little as may be possible. Gruels, chicken, dry toast, and plain biscuit, or food which is equally light and digestible, should constitute the diet during the attack.

Since there is no known specific for seasickness, and since even the palliative effects of many of the remedies used are doubtful, the various "cure alls" advised by well meaning friends should be sedulously avoided. Complete rest is the safest and surest remedy.

As soon as the invalid begins to improve he should by all means spend an hour or two in the open air, even if able only to sit quietly in his deck chair, since the fresh air is of great benefit in expediting his recovery.

However hungry he now may be, the patient should still be abstemious in diet, but he may have a little champagne, which should be well iced, and which must be sipped very slowly.

Nothing is now better than plenty of exercise, such as walking, deck cricket, or any out of door game which will promote alimentation and help to restore the disordered system to its normal balance.

By following these directions, the traveler can usually escape any extreme degree of prostration and is frequently able to shorten the average week of discomfort to a period of forty-eight hours.

Correspondence.

LETTER FROM ALBANY.

(From a special correspondent.)

The Annual Meeting of the Medical Society of the State of New York.—Continued Work in the Attempt to Secure Union of the New York State Medical Association with the Society.—A Broader Basis of Membership Recommended.—Legislation During the Past Year.—The State Hospital for Incipient Tuberculosis.

ALBANY, N. Y., February 1, 1905.

The president of the Medical Society of the State of New York, in his inaugural address, in which he usually outlines the matters which he recommends for executive action by the society, dwelt especially on the necessity for reaffirmation of the resolution for the consolidation of the two State medical bodies. The reason for this lay in the fact that certain legal obstacles had arisen which had retarded the union. The committee appointed to act in the matter of union reported later, reiterating the need for some action along the line suggested in the president's address. They also gave notice of resisting the legal action brought to prevent the consolidation, and gave their reasons for this proceeding, and they intend taking further action on the matter at the special meeting, which will be held after the close of the annual meeting of the society. The recommendations of the committee were adopted by the society.

The president recognized the growing sentiment for a less exclusive plan of organization in the matter of membership and recommended that the delegate system, which had been the usage hitherto, be abolished and that eligibility to membership be based only on good standing in the county societies. Thus every member of a county society will become *ipso facto* a member of the State organization. The committee to whom this matter was referred recommended the adoption of a resolution embodying the president's suggestions, which was promptly presented and accepted by the society. This complete change in the method of membership was not hastily made, as a similar proposition is embodied in the resolution for consolidation with the State association, so that whatever may happen to the agreement for consolidation, whether success or failure, each member of a county society will be a member of that of the State also.

The Committee on Legislation reported that the only measure of interest related to acts enabling the two medical bodies of the State to unite, and these had been passed. There had been a marked diminution in the number of bills introduced affecting the medical profession, and every measure actively

supported by the profession had become a law, among them an act for the establishment of a standard of pure milk for cities. One of the bills opposed because of its tendency to undermine the present standard of medical education was the so called optometry bill, enabling all opticians to "refract" eyes, and creating a State board of examiners in optometry which was to pass upon the qualifications for fitness of applicants for registration. Many of the best men in the profession of medicine had fought for years to raise the standard of medical education high enough to keep out charlatanry, and it was felt that this bill was merely the opening wedge for a host of "pathies" which would follow in its wake. This bill was therefore vigorously opposed by the committee and failed of passage. The society at the present meeting adopted resolutions instructing the committee to oppose the bill which would again be introduced in the legislature at the present session.

The report of the superintendent of the State Hospital for Incipient Tuberculosis, at Raybrook, Dr. John H. Pryor, was appended to the report of the Committee on Hygiene. While, as Dr. Pryor says, the time has been too short since its establishment to show any very definite medical report, the results of treatment as shown by him are on their face very encouraging. Since the hospital was opened on July 1st, up to the end of the year 1904, there were admitted eighty-two patients, of whom eleven were discharged, three apparently recovered, the disease was arrested in one, four improved, and three did not. Of the sixty-six patients in the hospital December 31, 1904, there were nineteen who had apparently recovered, thirty-four in whom the disease was arrested, thirteen improved, and none was unimproved. The average length of stay of patients discharged as apparently recovered was 14.4 weeks, while the average length of stay in hospital of those remaining and regarded as apparently cured was 17.6 weeks. The average gain in weight of all patients from July 1st to December 31st was 1.5 pound. The greatest gain in any one patient was 6 pounds in one week. He speaks with much favor of the employment of expert examiners for the examination of applicants for admission and deplores the large number of cases which are still allowed to reach advanced progress before recognition, thus minimizing the chances of recovery. The tent camps have proved a great success and have been highly praised by many visitors. At the present time seventeen States are either building similar institutions or following the lead of New York State in establishing a hospital for the consumptive poor. He also approves of the means taken by the charitable organizations of cities of

large size, who are cooperating with the officials of the institution to secure outdoor employment for discharged patients. He further deprecates delay in sending a patient after examination has been made. A patient may be a very favorable one at the time of examination and a very unpromising one a month later.

On Tuesday evening Dr. Charles Harrington, secretary of the Massachusetts State Board of Health, addressed the society in the Senate Chamber.

LETTER FROM PARIS.

The Need of Preparation for Study in Paris.—Public Comfort Stations.—A Judicial View of Medical Fees.—Poisoned Ducks.—Priests in Medicine.

PARIS, January 20, 1905.

A perplexed American whom I met recently had only made the mistake that hundreds make in coming here to finish medicine without a knowledge of the first rules of the game. If one contemplates a year of study here, it is the part of wisdom to study French customs in advance, and to get advice of some who have gone before as to boarding houses, clubs, cafés, reading rooms, etc. The French mode of life is not to be adopted at a moment's notice, and of the American quarter the French students have but the vaguest ideas. There is abundance of material here at the hospitals—those wretched hospitals—but it is best to know the way about beforehand. I have met a student who was pleasantly surprised to hear, after he arrived here, that it was in Paris that the Salpêtrière was situated, and concerning the purposes of the Pasteur Institute he was decidedly hazy. A few letters of introduction will do no harm, and I have heard it said that a knowledge of the French tongue is apt to be of aid when conversing with a Frenchman. At the American Art Association, 74 rue Notre Dame des Champs, at Donald Downie's, 1 bis rue Scribe, and at the office of the *Paris Herald*, 49 avenue de l'Opéra, an American exile can get much comfort. But a proper preparation in advance is strongly to be advised.

An American friend writes of the eight "public comfort" stations that New York contemplates. There are here in Paris probably eight hundred. The need and the value of such stations are obvious. It is not the obvious need, however, that guides the Parisian health department, but rather the spectacular nature of the thing and the further fact that the little kiosques for the purpose are not eyesores, as might be sup-

posed, but have on the contrary a decorative effect—an important consideration in a "show" city.

To beautify the city, blocks of the slums will be torn down, but hardly will this be done where sanitation is the primary object. An action such as that of New York in tearing down the Mulberry Bend buildings would be a rarity. Familiarity with Parisian conditions almost forces me to think that humanity is a minus quantity, and while the big hospitals are doing great work, it is not humanity that underlies it. If there is a good to be done that is *bizarre*, or that the whole world can read about, it is done with a flourish. Anything connected with the government has a badge as big as a shield of Thor to blazon its purpose. But petition some official about the insanitary water closet in your hotel, and you might as well bay the moon. Ninety-nine out of a hundred water closets are probably worse. And if you are a Frenchman, what's the use of bothering about such pettiness? Don't you house your servants in leaky attics, feed them on scraps, arrange their hours of work so that no minute is left unoccupied, and pay them such a low wage that only one interpretation can be put on their finery? Fine folk who practise such refined cruelties can hardly be expected to care whether the ditch digger of the slums lives on the stale brains of the horse or not, and even if the fine folk have the degree medical they are not agitated by the fact that on one small block last year a hundred people died of consumption.

A French doctor has been adjudged extortionate, and the seventh chamber of the local tribunal has decreed that four hundred dollars is too much to charge for eighty visits. Said visits were made too frequently—"sometimes two a day." The nature of the illness did not justify such frequent visits or a fee higher than two dollars a visit. The complainant was an American!

Some months ago a large number of deaths were due to the eating of poisoned duck. But the duck is again in vogue, for the pleasant Loubet, in compliance with a petition from the game dealers, has included it again in the bill of fare of the palace.

When the Jesuits had their troubles, years ago, many of the proscribed ones took to medicine as a pursuit. Now that the congregation of the Propaganda has decided that a priest under some conditions may practise medicine, it is possible that a certain clerical element may enter into the schools again. This decision will be good news to the congregations that have been disbanded, and it is possible that science may profit by it.

NEW YORK, SATURDAY, FEBRUARY 4, 1905.

THE TONGUE IN TROPICAL ABSCESS OF THE LIVER.

A writer in the *Semaine médicale* for December 7th calls to mind the classical symptoms of acute hepatitis—jaundice of varying intensity; spontaneous pain in the right hypochondrium, sometimes dull and deep seated, at other times sharp and lancinating, radiating toward the epigastrium and the right shoulder, and much aggravated by pressure; an appreciable enlargement of the liver; localized œdema of the abdominal wall; and fever with loss of appetite, more or less vomiting, and occasionally hiccough. But this clinical picture, he remarks, is far from being always well defined. In fact, he says, there is not a single one of these signs and symptoms that may not be lacking; moreover, several of them are frequently absent. Then the diagnosis, especially at the outset, becomes obscure, and the obscurity is all the greater in subacute and chronic cases.

But the writer cites Dr. H. de Brun, professor of clinical medicine in the French faculty of medicine in Beyrut, as attaching pathognomonic significance to the condition of the tongue. The tongue in tropical abscess of the liver is, indeed, ordinarily described as dry, coated at the centre, and with a bright red margin. But this description is not sufficiently precise for M. de Brun.

The tongue, he says, is at first covered with a saburral coat, but it loses that, and then its edges become of a red color. Sometimes there is a third red stripe extending from the tip to the base in the median line. When this supplementary stripe is present, there is a striking appearance of the tongue with its three red rays converging to its tip. When the epithelium is shed—and the fall may take place sooner over one lateral half of the organ than over the other—the whole tongue becomes of a bright strawberry red. Doubtless much importance is to be attached to the observations of M. de Brun, but we fancy that few would thrust an aspirator needle into the liver on the strength of such an appearance of the tongue as he describes.

"CHLOROPALUDISM."

The French form of this word, *chloropaludisme*, is assigned by an Athenian physician, Dr. Sakorraphos, to a morbid condition that he thinks is very probably of malarial origin. In the January number of the *Revue de médecine* he gives the histories of five cases, and says that he has seen twice that number. They all occurred in persons between fifteen and twenty-five years of age. Most of these young persons had had intermittent fever in some rural district and had subsequently gone to live in Athens. It is stated concerning several of them that they had but few if any more febrile attacks after taking up their residence in that city, but became the subjects of the peculiar condition described.

Patients affected with "chloropaludism" are all pale, looking as if they had grave chlorosis or leucæmia, and they complain particularly of extreme weakness. On account of this weakness several of Dr. Sakorraphos's patients had to give up work, although they had gone to Athens in quest of employment. They had some enlargement of the liver and of the spleen, though the spleen was not so much enlarged as is commonly the case with persons who have long had malarial disease. There was extreme pallor of the skin, with decoloration of the visible mucous membranes. There were no enlarged lymphatic glands. In every instance the stomach was more or less dilated, and digestion was impaired. In no case was there any elevation of temperature.

The condition of the blood and the absence of cardiac signs and symptoms distinguished the condition sharply from simple chlorosis. There was no augmentation of the number of hæmatoblasts, and there was no disproportion between the amount of hæmoglobin and the number of red corpuscles. Moreover, there was no change in the shape of the corpuscles. There was always an increase of the number of lymphocytes, and this increase is held by the author to be indicative of past malarial disease. Nothing is said of the treatment employed.

"PROFESSIONAL" SYPHILIS.

Accidental inoculation with syphilis is an ever present danger with medical men. There seems to be a more or less current impression that syphilis following extragenital inoculation is exceptionally malignant, but at a recent meeting of the Berlin Medical Society (*Semaine médicale*, December 28th) Dr. Blaschko, who had observed twelve cases of such inoculation among physicians, combated the idea, suggesting that any apparent extraordinary malignancy in such cases was explained readily by the frequency with which the true nature of the initial lesion was overlooked for a time, so that appropriate treatment was not instituted early. On the other hand, it is not very uncommon for other lesions of the fingers to be mistaken for chancres, and in the discussion following the reading of Dr. Blaschko's paper instances of accidental vaccination of the fingers thus misinterpreted were mentioned.

The point was brought out that in operating on syphilitic subjects there was probably little if any danger of inoculation so long as the tissues operated on were not themselves the seat of syphilitic manifestations, the blood itself not being prone to convey the disease unless it gained access to the system of the recipient in considerable quantity, as was years ago maintained by the famous "anonymous surgeon of the Palatinate." Allusion was made, as it always is on such occasions, to the necessity of precautions as to the recognition of minute solutions of continuity of the skin of the fingers, as to the use of rubber coats and gloves, and as to the advisability of immediately cauterizing cuts and punctures of the fingers during operations, but nothing particularly new was mentioned.

We think it well to caution our readers against

too implicit reliance on the doctrine that syphilitic blood is not apt to convey the disease unless it gains access to the system in large quantity, and we do not advise trusting to the innocence of those tissues of a syphilitic that do not happen to be the seat of the peculiar manifestations of the disease. The only safety, it seems to us, lies in assuming that any patient may be syphilitic and that a syphilitic person is syphilitic throughout. Such an assumption can do no harm, and it may be the means of averting disaster.

EXPLORATORY ABDOMINAL SECTION.

There exist undoubtedly potent factors in the methods of practice and in the daily routine of a medical, as distinguished from a surgical, life which have caused the attacks which, from time to time, representatives of each cult have made upon the other and, to be more specific, which have led to the condemnation by medical men at various times, and notably recently, of exploratory abdominal section. Only when such a protest emanates from such a source as to be widely and deeply heeded need our position be defended, and it therefore seems to me that this is an appropriate opportunity. I believe, indeed, that this condemnation has been unfairly presented and that, moreover, there exists, upon grounds as old as the earliest history, a very potent reason why it should not be made at all by medical men unless they are ready to uphold equally sweeping condemnation of exactly similar proceedings upon the part of their own particular fraternity, and this whether or not one or both sides of the question are actually in need of any revision whatever, which latter point, to my mind, has never yet been clearly proved.

If there is aught which more than all else characterizes the work of the surgeon and distinguishes it from that of the medical man, in the strict, distinctive use of this latter term, it is the necessity for exactitude in his first, his working diagnosis, because of the absolute certainty that if he commits a diagnostic error, as his all-important therapeutics, his operation, follows this diagnosis often immediately, he will of necessity also commit a therapeutic error, and from the nature of his therapy this is an error which cannot be counteracted or undone, and which must, moreover, be immediately detected.

And such detection is rarely indeed confined to the surgeon and his personal assistants, but is, in the case of the specialist, shared by the physician who referred the case, by the nurses in attendance at the operation, and by the patient's family, because even though the surgeon might be found who would feel inclined, either through a natural chagrin or a less worthy motive, to conceal the error from these latter, the fact that the secret was shared by too many would prevent such a course. What, then, in a doubtful case is left but a choice between a passive watching of the inroads of a perhaps fatal malady and the exploratory section, which may be also used for therapeutic purposes once the diagnosis is thus correctly established?

But for a moment consider the other side of the question. The medical man goes his solitary round to visit his patients. One is encountered in whom the symptoms are such as to preclude the possibility of a definite diagnosis. His course is invariably to treat the symptoms while awaiting the development of additional factors which shall declare their cause unmistakably. Thus far the course of the physician and that of the surgeon have been identical, for certainly no surgeon advocates exploratory section in a case which can with safety be treated medically and symptomatically. But in the event of such declaration failing, with a steady sinking upon the part of the patient, in fact in the event of the arrival of the moment at which, in a surgical case, exploratory section would be indicated, what is the course of the medical man in a purely medical case? Consultation is advised, and, this resulting in a continued doubt, the treatment considered best for the most probable cause of the illness is instituted. Examples such as that of giving iodides in suspected, obscure syphilitic manifestations or quinine in similar malarial conditions are too familiar to need citation. But they are merely types of a large class. In comparative innocence these examples compare favorably with a well chosen, properly executed exploratory section. To state the case in another way, the medical man is making his form of exploratory therapeutics serve his diagnostic ends.

The cases in which this method of procedure is applicable may be dealt with in either of two ways. The physician may declare his doubt and his purpose, or he may allow those interested to believe

that the medicine is rationally indicated by a positive diagnosis, and none can be the wiser. To such "medical explorations" there are three possible terminations. The first is that the medical man, having, either to gratify the family or to hide his perhaps perfectly excusable doubt, given the disease a name, has declared a diagnosis in which he has not full faith. In watching the result of his "therapeutic exploration" the correct diagnosis becomes evident, the treatment is promptly adjusted, and all goes well, no one but the doctor himself ever suspecting that the original diagnosis was incorrect. The second eventuation is that of consultation and conjoint "therapeutic exploration," with or without a full statement of facts and with or without success. The third outcome possible is that of death resultant from a steady progress of an uncomprehended malady, generally in spite of and rarely because of the individual or conjoint "therapeutic exploration." But how, except in the items of the armamentarium, does this differ from the condemned exploratory abdominal section?

The existence of examples such as those above cited does not in any manner reflect upon those men, either medical or surgical, who frankly pursue the more dignified and open course, nor does it diminish the undoubted justifiability of either form of exploration in selected cases under correct circumstances. It is not my object to decry "therapeutic exploration" in such suitable cases, of which there are many, but simply to protest against its employment by the very men who deny our right to employ an exactly analogous resource in cases in which otherwise neither medical nor surgical means appear able to save the endangered life. My object is rather to hold up the mirror to those medical men, again in the restricted sense of the term, of note and fame who attack exploratory abdominal section and attribute to it a fictitiously high mortality, without also admitting that equal, if not greater, harm may be done by their "therapeutic exploration." In compiling statistics of mortality due to exploratory abdominal section the same error has been made by our confrères which is so constantly and unjustly made by the lay press, namely, that of confounding *post hoc* and *propter hoc*. The lay press invariably says that Mr. A. died as the result of a surgical operation, instead of having due regard to the use

of the English language and the truth and saying that Mr. A. died of his disease in spite of an operation undertaken for its cure.

Therefore our position is this: Cases that might perhaps otherwise end in recovery may very rarely be harmed or even fatally terminated by an exploratory abdominal section, but when compared with the number of cases in which the exploration results in a clear diagnosis, after which proper surgical therapeutics may be administered through this same incision and a life saved free from disease, they seem few indeed, and, though they were even greater in number, they would still be defensible. On the other hand, many cases of obscure disease steadily progress to a fatal issue in spite of an exploratory incision, their course being apparently in no wise affected by such incision. Neither of these postulates is, however, susceptible of absolute proof, because no man can forecast the duration of any human existence.

Medical men should, then, go over their own records and compile the statistics of those cases in which "therapeutic exploration" has been employed and tabulate them in parallel columns with their statistics of exploratory abdominal section, and give us both sides at a glance and let us all judge of their right to dictate or even criticise. But such figures must not be strictly personal on either side. If by such a method it still is found that either method is really wantonly destructive of life, either side will be ready to adopt safer methods if they are forthcoming, but in the mean time it appears that neither possesses the right to assail the other's use of methods the exact analogue of those constantly employed by those upon his own side of the question.

DANIEL H. CRAIG.

YEAST AS AN ADJUNCT IN THE TREATMENT OF PHLYCTÆNULAR CONJUNCTIVITIS.

It is a great mistake to take it for granted that a local morbid manifestation is amenable only to topical treatment. As an illustration of this fact we may mention the experience of Dr. E. Ginetous, of Bordeaux, in the internal use of yeast as an adjuvant in the treatment of phlyctænular conjunctivitis, cited in the *Semaine médicale* for January 18th. In the treatment of twenty-five cases he has found the cure indisputably hastened by the employment of yeast—a drachm in twenty-four hours in the case of adults, and half that quantity in children. In many instances the trou-

ble proved rebellious to local treatment alone, but at once began to yield when the internal administration of yeast was associated with it. The effect is explained on the theory that the affection is generally of staphylococcal origin.

MAJOR HODDER'S WORK IN THE DESTRUCTION OF MOSQUITOES.

It appears from a brochure recently issued by Major W. M. Hodder, of the Royal Engineers of the British Army, that very effective work has been accomplished under his direction in Santa Lucia in the suppression of mosquitoes in one of the West Indian islands. With the practical concord as to the part played by *Anopheles* and *Stegomyia* in the conveyance of disease that now exists, and virtually international cooperation in attempts to guard against their attacks, there ought soon to be accomplished a great deal in the way of permanently stamping out the diseases that are chiefly if not entirely propagated by those pests.

PRIVILEGES FOR HOSPITAL SHIPS.

A diplomatic conference called by the French government was recently held at the Hague and resulted in the appointment of a commission to prepare articles according certain privileges to hospital ships, especially that of exemption in time of war from charges in the ports of the signatory powers. Twenty-one such powers were represented, and others may become parties to the arrangement. It is to be regretted that, as we learn from the *Gazette médicale de Paris*, Great Britain's own maritime laws prevent her from taking part in the convention.

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The ninety-ninth annual meeting of the society, held in Albany this week, dealt with an ample programme of scientific work and abundantly maintained the reputation of the organization as a representative of the profession of the State. In addition, all that was practicable was done toward bringing about the amalgamation of the New York State Medical Association with the society.

AN ASTOUNDING PIECE OF QUACKERY.

Last week the newspapers gave the particulars of the swindling of a man by a quack establishment in New York. Under the pretense of using a very expensive medicament, radium, the man was fleeced of thousands of dollars, though it appears that no radium was employed. Before the arrest of the chief perpetrator of this swindle the same newspapers had displayed his lying advertisements without any apparent hesitation.

Society Meetings for the Coming Week:

MONDAY, February 6th.—New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association; Providence, R. I., Medical Association; Hartford, Conn., Medical Society; South Pittsburgh, Pa., Medical Society; Chicago Medical Society.

TUESDAY, February 7th.—New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, February 8th.—Medical Society of the Borough of the Bronx, New York; New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Pittsfield, Mass., Medical Association (private); Philadelphia County Medical Society; Lenox Medical and Surgical Society (private).

THURSDAY, February 9th.—New York Academy of Medicine (Section in Pediatrics); New York Academy of Medicine (Section in Otolaryngology); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, February 10th.—Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genitourinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, February 11th.—Obstetrical Society of Boston (private).

Change of Address.—Dr. Matthias Lanckton Foster, to 616 Madison Avenue; telephone number, 1470 Plaza.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 28, 1905:

	January 28.		January 21.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	174	7	194	4
Diphtheria and croup.....	272	40	360	40
Scarlet fever.....	248	13	289	14
Smallpox	8
Chickenpox	174	..	179	..
Tuberculosis	389	167	404	153
Typhoid fever.....	41	14	50	12
Cerebrospinal meningitis.....	..	28	..	30
	1,306	269	1,476	253

Fire in a New York Hospital.—The chapel connected with the Misericordia Hospital in East Eighty-seventh Street, New York, was damaged by fire to the extent of \$5,000 on January 26th. The inmates of the hospital were removed to a distant wing, but they were at no time in danger.

Obituary Note.—Dr. Patrick J. McGrath, who acted as surgeon to one of Peary's arctic expeditions and who later served as an army surgeon in the Philippines, fell from the steps of his home

in East Thirty-fourth Street, New York, on January 28th, and died later of his injuries.

Mount Sinai Hospital.—The eighth annual reunion and dinner of the Associated Alumni of Mount Sinai Hospital was held at the Freundschaft Society on Wednesday evening, January 25th. The following officers were elected for the ensuing year: President, Dr. Fred. Mandelbaum; vice-president, Dr. Louis Houswirth; secretary, Dr. Leo B. Meyer; treasurer, Dr. Andrew Green Foord.

Bequest to Brooklyn Hospital.—The Brooklyn Hospital has just received from A. Victor Barnes and Harriet Barnes Newberry a gift of \$1,500 "to be used in any manner which seems advisable," in memory of their father, the late General Alfred Cutler Barnes. The hospital officers state that, in accordance with their custom in all cases of bequests they have added the Barnes gift to the permanent endowment funds.

E. R. Squibb & Sons, Incorporated.—The firm of E. R. Squibb & Sons, of Brooklyn, has been incorporated, and Mr. Theodore Weicher, formerly the senior partner in the firm of Merck & Co., has been elected president of the corporation. Dr. Edward H. Squibb and his brother, Mr. Charles F. Squibb, retain their interest in the firm, both being members of the board of directors, of which Dr. Squibb is chairman.

Dr. Cordelia A. Greene, aged 74 years, one of the oldest women physicians in the country, died in New York last week in spite of an operation. For nearly fifty years she had owned a sanitarium near Buffalo. Dr. Greene was a graduate of Western Reserve University and of the Woman's Medical College of Philadelphia, and was a member of the New York State, Wyoming County, and American Medical Associations. She was the daughter of Dr. Jabez Greene, of Clifton Springs and Castile, N. Y., famous years ago as a sanitarium physician.

Academy of Medicine.—A stated meeting will be held in Hosack Hall on Thursday, February 2nd, at 8.15 p. m. Order: The Hypodermic Use of Adrenalin Chloride in Asthmatic Attacks, by D. M. Kaplan, M. D.; Anæmia Due to Intestinal Parasites, by W. Gilman Thompson, M. D.; Cases of Anæmia Due to Intestinal Parasites, by Alfred Meyer, M. D., and W. P. Northrup, M. D. Discussion. The Limitations of the Value of Nitroglycerin as a Therapeutic Agent, by H. P. Loomis, M. D. Discussion. Charles F. Adams, M. D., assistant secretary, 104 West Seventy-third Street.

The section in surgery will meet on Friday, February 3rd, at 8.15 p. m. Order: Presentation of Patients; Chronic Osteomyelitis of Femur (two cases) Treated by Iodoform-wax Filling, by C. A. Elsberg, M. D.; Chronic Osteomyelitis of Ulna (two cases) Treated by Iodoform-wax Filling, by C. A. Elsberg, M. D.; Faciohypoglossal Anastomosis (two cases), by A. S. Taylor, M. D.; Keloid of Face, by H. P. Moseley, M. D.; Keloid of Anterior Thoracic Wall, by H. P. Moseley, M. D.; Keloid of Neck, by H. P. Moseley,

M. D.; Healed Keloid, by A. E. Gallant, M. D.; papers, On the Treatment of Chronic Osteomyelitis and of Chronic Bone Cavities by the Iodoform-wax Filling, by C. A. Elsberg, M. D.; discussion opened by Virgil P. Gibney, M. D.; Treatment of Keloid by the X Ray, by Henry Perkins Moseley, M. D.; discussion opened by Arthur L. Fisk, M. D.; The Present Status of Blood Examination in Surgical Diagnosis, by Frederic E. Sondern, M. D. Discussed by Dr. Joseph A. Blake, Dr. Francis H. Markoe, Dr. Edward Quintard, and Dr. Francis C. Wood. Presentation of new instruments: Special Instrument for Facio-hypoglossal Anastomosis, by A. S. Taylor, M. D. Samuel Lloyd, M. D., chairman; Warren S. Bickham, M. D., secretary, 10 East Fifty-eighth Street.

The section in pædiatrics will meet on Thursday, February 9th, at 8.15 p. m. Order: Presentation of Patients; Reports of cases: Syphilitic Pseudoparalysis, by Jacob Sobel, M. D.; paper, The Digestion of Caseins, and Its Relation to Certain Problems in Infant Feeding, by Thomas S. Southworth, M. D. Discussion by Dr. H. D. Chapin, Dr. W. Gilman Thompson, Dr. W. L. Carr, Dr. F. M. Crandall, Dr. C. G. Kerley, Dr. G. R. Pisek, and others. L. E. La Fetra, M. D., chairman; John Howland, M. D., secretary, 49 East Fifty-third Street.

The section in otology will meet on Thursday, February 9th, at 8.15 p. m. Order: Report of a Case of Double Mastoiditis with Extensive Involvement of the Zygomatic Cells, by W. P. Brandegee, M. D.; A Preliminary Report of a Case of Cholesteatomatous Disease, with Stenosis of the External Auditory Canal, Extensive Destruction of the Temporal Bone, and External Manifestations, by M. D. Lederman, M. D.; A Condensed Report of a Case of Streptococcic Otitis Media, Followed by Mastoiditis; Operation; General Septicæmia; Death, by C. G. Coakley, M. D.; A Report of a Case of Infective Sinus Thrombosis, Complicated by Meningitis; Lumbar Puncture and Subdural Irrigation, by J. D. Richards, M. D.; paper, Some Mooted Points in the Treatment of Protracted Cases of Acute Middle Ear Diseases and Their Complications, by Alfred Weiner, M. D. Emil Gruening, M. D., chairman; W. H. Haskin, M. D., secretary, 42 East Forty-first Street.

PHILADELPHIA.

Change of Address.—Dr. G. Hudson Makuen, to 1627 Walnut Street.

Sentenced for Criminal Abortion.—On January 25th, Mrs. Elizabeth Ashmead was sentenced to three years' imprisonment for performing a criminal operation, which resulted fatally.

Piano Recital for Jefferson Hospital.—Miss Adele aus der Ohe gave a piano recital in Witherpoon Hall on January 24th for the benefit of the Jefferson Maternity Department of the Hospital.

Northern Medical Association.—At the meeting of the Northern Medical Association, held January 27th, Dr. A. A. Eshner read a paper on

Epilepsy. The discussion was opened by Dr. W. E. Pickett.

Personal.—Dr. Francis M. Perkins was operated upon in the German Hospital on Sunday, January 15th, for appendicitis. Dr. Perkins's condition was satisfactory at the last report.

Dr. John H. Jopson has been elected visiting surgeon to the Presbyterian Hospital.

The board of trustees of the Medico-Chirurgical Hospital has promoted Miss Edith McPherson to be Superintendent of Nurses.

The West Philadelphia Medical Association was organized on January 14th with the following officers:

President, Dr. A. F. Targetts; vice-president, Dr. George C. Shammo; recording secretary, Dr. William D. Beacon; financial secretary, Dr. A. P. Good; treasurer, Dr. J. D. Brittingham; directors, Dr. J. H. McConnell, chairman, Dr. E. L. Graf, Dr. S. F. Gilpin, Dr. H. B. Smith, Dr. Frank B. Kirby, Dr. F. Mortimer Cleveland, Dr. F. R. Starkey, Dr. B. F. Wentz, Dr. A. P. Good, Dr. Charles E. Price, and Dr. J. D. Brittingham. The association will meet on the second Friday night of each month in Rittenhouse Hall, Fifty-third and Haverford Streets.

The Alumni Association of the Medico-Chirurgical College has elected the following officers:

President, Dr. William L. Shindel; secretary, Dr. Stillwell C. Burns; treasurer, Dr. Emanuel S. Gans; executive committee, Dr. W. Easterly Ashton, Dr. Albert E. Blackburn, Dr. Arthur C. Buckley, Dr. L. Napoleon Boston, Dr. Joseph A. Cramp, Dr. John Welsh Croskey, Dr. Morton P. Dickeson, Dr. John H. Egan, Dr. L. Webster Fox, Dr. Andrew Godfrey, Dr. Charles H. Gubbins, Dr. S. Leon Gans, Dr. A. Wiese Hammer, Dr. W. Frank Haehtlen, Dr. Harry Lowenburg, Dr. Francis Lammer, Dr. John A. McGlinn, Dr. John A. McKenna, Dr. George W. Pfromm, Dr. J. V. C. Roberts, Dr. Herbert J. Smith, Dr. John V. Shoemaker, Dr. M. P. Warmuth, Dr. John W. Wilkins, Dr. J. L. Widmyer.

Free Hospital for Poor Consumptives.—A bill to appropriate \$300,000 to the Free Hospital for Poor Consumptives at White Haven has been introduced into the State legislature by Representative Shern. Of this sum \$100,000 is for the maintenance of the sanatorium at White Haven; \$100,000 to assist in the erection and equipment of new buildings to increase the capacity to as near 300 beds as possible, and \$100,000 to assist in purchasing a site at a suitable location and in erecting buildings for the care of more advanced cases of tuberculosis than can be accommodated at White Haven.

Annual Meeting of the Managers of the Children's Hospital.—The forty-ninth annual meeting of the contributors and managers of the Children's Hospital was held on January 13th in the hospital. John Cadwalader, Jr., presided. The following were elected managers for three years: Richard Wood, Edward S. Sayres, Eckley B. Cox, Jr., William White, Jr., Emlen Hutchinson, and Clarence H. Clark. Dr. T. Hewson Bache was made director emeritus. Charles Platt was chosen president of the board of managers. The other officers elected were: Vice-president, Emlen Hutchinson; secretary, Edward S. Sayres, and treasurer, Charles W. Cushman.

Scientific Society Meetings for the Week Ending February 11, 1905.—Monday, February 6th, Philadelphia Academy of Surgery; Biological

and Microscopical Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, February 7th, Academy of Natural Sciences. Wednesday, February 8th, Philadelphia County Medical Society. Thursday, February 9th, North Branch, Philadelphia County Medical Society; Pathological Society. Friday, February 10th, Northern Medical Association; West Philadelphia Medical Association. Saturday, February 11th, West Philadelphia Branch, Philadelphia County Medical Society.

Wills's Hospital.—Realizing the importance of a society in which clinical workers in ophthalmology may be able to report their interesting daily cases and enjoy full and free individual discussion upon the same, and present theoretical and statistical papers upon ophthalmic subjects, Dr. Oliver, of Philadelphia, has recently organized the Association of Clinical Assistants of Wills's Hospital. Membership by ballot is open to all those who have been or are connected with one or more of the clinical services in Wills's Hospital for a period of not less than three months' time. Meetings are held at the hospital at 8.30 p. m. on the first and third Wednesdays of each month. All who are eligible are invited to attend and join.

The Health of the City.—During the week ending January 21, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	80	12
Scarlet fever.....	56	2
Chickenpox.....	94	0
Diphtheria.....	96	10
Cerebrospinal meningitis.....	1	0
Measles.....	12	1
Whooping cough.....	10	2
Tuberculosis of the lungs.....	35	62
Pneumonia.....	70	68
Erysipelas.....	12	4

The total death rate was 519, in an estimated population of 1,438,318, corresponding to an annual death rate of 18.76 per 1,000 population. The total infant mortality was 106; 93 under one year, and 13 between one and two years. There were 42 still births; 25 males and 17 females. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 4; puerperal fever, 1; diarrhoea and enteritis under two years, 8. The weather was unusually mild and pleasant.

Appropriations Recommended for Charitable Institutions.—In the report of the State Board of Charities, which will be sent to the legislature during the first week in February, the State, partly State and private charitable institutions are recommended for appropriations aggregating \$9,406,923.75. The following are the amounts recommended for various Philadelphia hospitals: University Hospital, \$250,000; Jefferson Medical College Hospital, \$250,000; St. Timothy's Hospital, \$23,500; Kensington Hospital for Women, \$5,000; Philadelphia Polyclinic Hospital, \$65,000; Medico-Chirurgical Hospital, \$250,000; Rush Hospital for Consumptives, \$30,000; St. Mary's Hospital, \$8,500; St. Christopher's Hospital, \$15,000; Lying-in Charity Hospital, \$16,000; Ortho-

pædic Hospital, \$20,000; Maternity Hospital, \$6,000; Gynecean Hospital, \$25,000; Samaritan Hospital, \$40,000; German Hospital, \$30,000; Howard Hospital, \$5,000; West Philadelphia Hospital for Women, \$5,000; St. Joseph's Hospital, \$10,000; Wills's Eye Hospital, \$20,000; Frankford Hospital, \$50,000; Jewish Hospital, \$15,000; Frederick Douglas Hospital (colored), \$12,000; St. Agnes's Hospital, \$20,000; Women's Hospital, \$12,500; Western Temporary Home, \$3,500; Northern Home for the Friendless, \$12,500; Pennsylvania Children's Aid Society, \$30,000; Nazarene Home, \$7,500; Rosine Home, \$4,000; Friend's Home for Children, \$4,000; Philadelphia Working Home for Blind Men, \$35,000; Penn Asylum, \$5,000; Home for Infants, \$4,000; Union Home for Old Ladies, \$5,000; Home for Aged Veterans, \$15,000; Home for the Aged, \$4,000; Old Ladies' Home, \$6,000; Hayes Mechanics' Home, \$5,000; Evangelical Home, \$2,500; Philadelphia Protectory, \$15,000; Home for Incurables, \$25,000; House of Good Shepherd, \$8,000; Philadelphia Sanitarium Institution, \$5,000; St. Vincent's Home, \$2,500; Pennsylvania Anti-Cruelty Society, \$5,000.

The Influence of Filtered Water on Typhoid

Fever.—The following information concerning the influence of filtered water on the incidence of typhoid fever is obtained from the bulletin of the bureau of health for January 7, 1905. During the year 1904, the influence of pure water upon the occurrence of typhoid fever is conspicuously manifested in the twenty-first and twenty-second wards, which are supplied with filtered water from the Roxborough filtration plant, and a portion of the twenty-seventh ward, which is supplied from the Belmont plant. The population of the former district is about 100,000; of the latter, 47,000. The highest number of cases reported from the twenty-first and twenty-second wards in any one week was twelve (week ending August 26th). Up to and including the week ending December 24th, there were sixteen weeks in which two cases or less were reported. For the year, the occurrence of typhoid fever corresponds to a weekly average of 4.3 per 100,000 population. Filtered water has been supplied to a portion of the twenty-seventh ward for twenty-eight weeks and for fifteen of these weeks no case of typhoid fever was reported. The highest number of cases reported in a single week was three, in the week ending December 2nd. This corresponds to a weekly average of 1.4 per 100,000 population. During the same period the weekly average of cases per 100,000 for the entire city was 6. Between March 26th and May 14th the city experienced a serious epidemic of typhoid fever. During this time 2,291 new cases were reported, corresponding to a weekly average of 25.3 cases per 100,000 population. During the same period fifty-three cases were reported from the twenty-first and twenty-second wards; an approximate weekly average of 7.5 cases per 100,000 population. In other words, during a serious epidemic of typhoid fever in the city as a whole the case incidence in the district supplied with filtered water was 66 per cent. less than in the other parts

of the city. Many of the residents of these districts spent a part of each day in portions of the city supplied with raw water only. The twenty-seventh ward cannot be used in this comparison, because it was not supplied with filtered water at that time. The evidence at hand warrants the prediction that when the filtration plants are all completed and the entire city is supplied with filtered water, there will be a reduction of at least 80 per cent. in the occurrence of typhoid fever.

GENERAL.

Wesley Memorial Hospital, Atlanta, Ga.—Over \$30,000 was collected for this institution in the Methodist churches of Georgia on Christmas Day.

The Beth Israel Hospital, of Newark, N. J., is to erect a three story building, owing to the demands for more room. The hospital will then be able to accommodate fifty patients.

Wyoming County, N. Y., Medical Society.—The following officers have been elected: President, Dr. Z. J. Lusk, of Warsaw; vice-president, Dr. G. S. Skiff, of Gainesville; secretary and treasurer, Dr. L. H. Humphrey, of Silver Springs.

The Practitioners' Society of the Oranges, N. J., has elected these officers for 1905: President, Dr. Francis R. Lane, of East Orange; vice-president, Dr. D. Warren Poor, of Orange; secretary and treasurer, Dr. Edgar Siebert.

The Woodford County, Ky., Medical Society has elected officers for 1905 as follows: President, Dr. S. M. Worthington; vice-president, Dr. W. C. Parker; secretary and treasurer, Dr. W. C. McCauley.

Sixty-fifth Regiment of the N. G. S. N. Y., Buffalo.—The resignation of Dr. Frederick Carl Busch, assistant surgeon to this regiment, has been accepted, and Dr. Marshall Clinton succeeded him on January 24th.

Obituary Note.—Dr. H. B. McConnell, a prominent practitioner of Boston, aged 34 years, died on January 25th, in spite of an operation. He was a graduate of McGill and Trinity Universities, and was for several years house physician at the Massachusetts General Hospital.

Dr. Henry Boynton, well known as a surgeon in the Civil War, died at his home in Woodstock, Vt., on January 30th, aged 81 years. He was the author of several historical and biographical works.

To Enlarge the Craig Colony for Epileptics.—A bill has been introduced into the New York legislature, making an appropriation of \$90,000 for additional cottages for patients. The census of the colony at present exceeds 1,000, and there are more than 700 applicants on the waiting list who cannot be admitted on account of lack of room. If the amount asked for becomes available, buildings for 200 additional patients can be put up. The per capita cost of construction is fixed by law at not to exceed \$450. A new feature of the work at Sonyea that is about to be established is a special building for epileptic infants; children under five years of age. Such a structure should

find a useful place in a colony for epileptics like the one at Sonyea.

Statement of Mortality in Chicago for the Week ending January 28, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905, and of 1,932,315 for 1904:

	Jan. 28, 1905.	Jan. 21, 1905.	Jan. 30, 1904.
Total deaths, all causes.....	308	301	549
Annual death rate per 1,000.....	14.61	15.47	14.85
By sexes—			
Males.....	312	331	308
Females.....	246	260	241
By ages—			
Under 1 year.....	148	117	124
Between 1 and 5 years.....	45	55	36
Over 60 years.....	115	131	126
Important causes of death—			
Acute intestinal diseases.....	16	23	14
Apoplexy.....	12	19	13
Bright's disease.....	12	5	24
Bronchitis.....	15	18	40
Consumption.....	60	77	57
Cancer.....	16	19	19
Convulsions.....	12	9	14
Diphtheria.....	12	9	7
Heart diseases.....	36	37	56
Influenza.....	9	22	7
Measles.....	5	5	0
Nervous diseases.....	30	20	23
Pneumonia.....	96	120	121
Scarlet fever.....	0	3	3
Smallpox.....	0	1	1
Suicide.....	6	9	5
Typhoid fever.....	7	9	5
Violence (other than suicide).....	33	26	27
Whooping cough.....	3	2	0
All other causes.....	141	111	113

Happily the apprehensions entertained during December and the early part of the present month have not materialized, and the twenty-eight elapsed days of January show a death rate of only 13.43 per 1,000 of population. The mean January rate of the decade, 1895-1904, was 15.70, or 14.4 per cent. higher. These apprehensions were based on the epidemic prevalence of influenza and the deficiency of sunshine during the period. During December there was but 33 per cent. of possible sunshine, as against an average of 37 per cent. during the previous ten Decembers, and there has been only 34 per cent. this month, instead of the normal 42 per cent. of January sun. Sunshine is the most potent disinfectant and germ destroyer, and the cloudy, foggy weather would, it was feared, materially increase the prevalence and mortality of all the germ diseases. This has proved only measurably true, and the state of Chicago's health, as indicated by the declining death rate and the almost stationary hospital population, must be accounted satisfactory for the season of the year. The exception is in the pneumonia mortality. During November, the first month of the current pneumonia season, there were 260 deaths reported from this cause—a daily average of 8.6. In December there were 451 reported—a daily average of 14.5 and an increase of 40 per cent. During the 28 days of January there have been 459 pneumonia deaths—a daily average of 16.4 and an increase of 11.5 per cent. over the December rate.

The Pharmaceutical History of the Civil War.—The Committee on Historical Pharmacy of the American Pharmaceutical Association has undertaken to collate data bearing on the military and naval pharmacy of the civil war, and has issued an appeal for information from all who have any knowledge of this subject. All who are in a posi-

tion to furnish any information on the subject, or who can suggest possible sources of information, are requested to communicate with either one of the officers of the committee, as follows: Albert E. Ebert, chairman, 426 State Street, Chicago; Professor Edward Kremers, historian, University of Wisconsin, Madison, Wis.; or Caswell A. Mayo, secretary, 66 West Broadway, New York.

Trinity Hospital School for Nurses, Milwaukee.—Members of the graduating class of this institution are: Mary I. Anderson, of Sheboygan; Emily L. Buchen, of Cascade; Marion Carlton, of Avening, Ontario; Elma E. Carroll, of Northport; Minnie I. Currie, of Collingwood, Canada; Harriett Dunning, of Marinette; Emaline C. Eschenbach, of Abelmans; Grace Gorman, of La Crosse; Mabel Guinan, of Webster City, Ia.; Margaret M. Hartigan, of Lake Linden, Mich.; Sybilla Huber, of Richland Centre; Margaret R. Kelly, of Minneapolis; Mary A. McGivern, of Fond du Lac; Elizabeth M. Pattinson, of Merrill; and Mrs. Jennie A. Cromwell, of Kansas City, Mo.

Chautauqua County Medical Association.—The election of officers of this association took place on January 17th with the following result: President, Dr. V. D. Bozovsky, of Dunkirk; first vice-president, Dr. B. S. Sweetland, of Brocton; second vice-president, Dr. Morris N. Bemus, of Jamestown; secretary and treasurer, Dr. H. A. Eastman, of Jamestown, reelected; trustee, Dr. H. F. Hunt, of Dewittville, reelected. Fellows to the meeting of the New York State Medical Association at New York in October: Dr. William M. Bemus, of Jamestown; Dr. George F. Smith, of Sinclairville; and Dr. J. A. Weidman, of Dunkirk. Dr. E. M. Scofield was elected a member of the nominating committee of the fourth district branch of the State medical association, which meets at Rochester in May.

New York Legislature Bill Concerning Habitual Drunkenness.—A bill, framed by Magistrate Pool, was, on January 16th, introduced into the Albany legislature by Assemblyman McManus, of New York. The measure concerns the treatment of persons rendered mentally or physically incompetent by the excessive use of alcoholic liquors, opiates, or narcotics. It directs that New York shall provide a hospital and a competent staff of physicians to deal with such cases. It also directs that the mayor shall appoint three physicians to serve in the hospital, which is to be supported out of money collected for excise taxes. Commitment to this hospital is to be made on the sworn application of a father, mother, or some other relative or friend of the person affected, or by a city magistrate. The new hospital is designed to take the place of the present alcoholic ward at Bellevue Hospital.

Hennepin County, Minn., Medical Society.—The Hennepin County Medical Society held its annual meeting on January 9th. Officers for the ensuing year were elected as follows: President, Dr. D. O. Thomas; vice-president, Dr. A. B.

Cates; librarian, Dr. S. M. White; executive committee, Dr. C. H. Bradley, Dr. J. W. Bell, and Dr. George G. Eitel; board of censors, Dr. R. J. Hill, Dr. W. B. Pineo, Dr. J. C. Litzenberg, Dr. George D. Head, and Dr. J. D. Simpson; trustees, Dr. H. H. Kimball, Dr. Edwin Phillips, Dr. W. A. Hall, Dr. G. C. Barton, and Dr. R. J. Hill; delegates to State convention, Dr. A. W. Abbott, Dr. F. A. Dunsmoor, Dr. G. G. Eitel, Dr. D. O. Thomas, and Dr. A. B. Cates; alternates for the five delegates in the same order as above, Dr. J. W. Little, Dr. L. A. Nippert, Dr. C. G. Weston, Dr. H. B. Sweetser, and Dr. A. J. Murdock. Dr. F. A. Knights, the present secretary and treasurer, holds over.

Vaccination of School Children Sustained by Court of Appeals in New York State.—Opinion of the court:

"The appellant claims that vaccination does not tend to prevent smallpox, but tends to bring about other diseases, and that it does much harm with no good. It must be conceded that some laymen, both learned and unlearned, and some physicians of great skill and repute, do not believe that vaccination is a preventive of smallpox. The common belief, however, is that it has a decided tendency to prevent the spread of this fearful disease and to render it less dangerous to those who contract it. While not accepted by all, it is accepted by the mass of the people as well as by most members of the medical profession. It has been general in our State and in most civilized nations for generations. It is generally accepted in theory and generally applied in practice, both by the voluntary action of the people and in obedience to the command of law. Nearly every State in the Union has statutes to encourage or directly or indirectly to require vaccination, and this is true of most nations in Europe. It is required in nearly all the armies and navies of the world. Vaccination has been compulsory in England since 1854, and the last act upon the subject, passed in 1893, requires every child born in England to be vaccinated within six months of its birth. It is compulsory, or is aided, encouraged, and to some extent compelled in the other European nations. It is compulsory in but few States and cities in this country, but it is countenanced or promoted in substantially all, and statutes requiring children to be vaccinated in order to attend the public schools have generally been sustained by the courts.

The opinion further states, that a common belief like common knowledge may be acted on by the legislature and courts without proof, and the fact that it is not universal is not controlling, for there is scarcely any belief that is accepted by every one, and what the people believe is for the common welfare must be accepted as for the common welfare. "While we do not decide and cannot decide that vaccination is a preventive of smallpox, we take judicial notice that this is the common belief, of the people of the State, and with this fact as a foundation, we hold that the statute in question is a health law, enacted in a reasonable and proper exercise of the police power."

Meeting of the Michigan State Board of Health.—The State Board of Health met in the capitol, January 20, 1905. The members present were: Victor C. Vaughan, M. D., Honorable Henry A. Haigh, D. A. MacLachlan, M. D., Collins H. Johnston, M. D., and Henry B. Baker, M. D., secretary. Dr. Vaughan was elected president *pro tem*. After the auditing of bills and accounts and the disposal of other necessary routine work; Dr. Baker presented to the board an important written report as chairman of the Committee on the Relation of Preventable Sickness to Taxation. The facts arrived at in this compilation are believed to be valuable, both from a public health and from a practical standpoint. The information has been collected from clerks.

of counties and of local boards of health, and it is proposed to send in return to clerks, supervisors, and health officers the printed report, that the information supplied by them and thus combined may be made available for showing just what diseases cost localities the most money to restrict, and whether or not the gain to the State because of the restriction of certain diseases warrants the expenditure. The board directed that this report be printed for distribution, as indicated above. The members present having learned of the sudden death of the president of the board, Honorable Frank Wells, Dr. Vaughan spoke briefly of the very efficient work of the late president, in his connection with the State Board of Health and public health interests of the State, and mentioned the valuable services rendered the State through the loyal and devoted efforts of this good man. The other members present reiterated what had been said by Dr. Vaughan and each spoke in very high terms of their relations with Mr. Wells as a member of the board. Resolutions submitted by Mr. Haigh, chairman of the committee appointed for that purpose, were adopted by the board as follows:

Whereas, This board has learned with deep sorrow of the sudden and untimely death of Honorable Frank Wells, for 14 years a member of the board, and its president for twelve years; and

Whereas, The great services rendered to this board by Mr. Wells and through it to the people of the State of Michigan, in the advancement of sanitation and public health, call for deepest gratitude, and also for some expression of appreciation more worthy and extended than can be embodied in any formal resolution; therefore

Resolved, That the secretary of this board be instructed to prepare a suitable memorial of these services, setting forth their character and great value, and embodying the fact that during the latter years of his life, Mr. Wells devoted practically his entire time to the advancement of the public health interests of the State, and that he labored efficiently in season and out, and all without thought of compensation or reward, for the good of his fellow men.

Resolved, That such memorial be published in the next annual report of the board.

Resolved, That this board extend its sympathy and condolence to the family of the deceased, and that a copy of these resolutions be suitably inscribed and sent to them.

Resolved, That as a mark of respect this board attend the funeral of the deceased in a body.

Resolved, As a further mark of respect, that this board do now adjourn.

The State Board of Medical Examiners of Pennsylvania met at the Hotel Walton, Philadelphia, January 2, 1905, to compare the averages of those who had taken the examinations December 16 to 19, 1904. There were 126 applicants for licenses; of these 40 failed to attain the legal average, and one was held under advisement, owing to some defects in papers. H. S. McConnell, M. D., secretary. List of applicants who successfully passed the State board examinations in Philadelphia, December 16 to 19, 1904:

Alexander C. Abbott, 4229 Baltimore Avenue, Philadelphia, Pa.; Andrew Franklin Akers, Hollidaysburg, Blair County, Pa.; Emilio De Antonio, 346 Franklin Avenue, Scranton, Pa.; Raymond Barber, Samaritan Hospital, Philadelphia, Pa.; Bertram Alexander Beale, Driftwood, Cameron County, Pa.; Hyman Bernstein, Government Hospital for Insane, Washington, D. C.; Lewis Clyde Bixler, 206 Spring Garden Street, Easton, Pa.; George Henry Bolling, 6375 Amelia Street, Pittsburgh, Pa.; James Lenon Brennan, 27 Bennett Street, Williamsport, Pa.; Stod-

dard S. Burg, Northumberland, Pa.; Leslie Chamberlain, 32 Dearborn Street, Philadelphia, Pa.; Ralph Oakley Clock, 3422 Sansom Street, Philadelphia, Pa.; Thomas Nicholson Craig, Medico-Chirurgical Hospital, Philadelphia, Pa.; Omar T. Cruikshank, 2220 Woodstock Avenue, Swissvale, Pa.; George Aloysius Cunningham, 204 West Centre Street, Mahanoy City, Pa.; Beatrice Magdalene Curran, 824 South Forty-ninth Street, Philadelphia, Pa.; Edward Martin Dailey, 19 Hemlock Street, Danville, Pa.; Jonathan Raynor Day, West Finley, R. F. D. No. 75, Washington County, Pa.; Luther E. Evans, corner Broad and Centre Streets, Alton, Ohio; Mauricio Flores y Fernandez, 804 Ann Street, Homestead, Pa.; Harry Spaulding Fish, Waverly, Tioga County, Pa.; Wilbur Allen Foster, 533 South Main Street, Wilkes-Barre, Pa.; Samuel R. Fraker, Fort Littleton, Fulton County, Pa.; William Garretson, 1845 Forty-first Street, Philadelphia, Pa.; William Pounder Gillespie, Jr., 1725 North Twenty-ninth Street, Philadelphia, Pa.; Frank D. Glenn, 118 Fifth Avenue, Carnegie, Pa.; Lee McKluskie Goodman, Logantown, Clinton County, Pa.; John Odie Grove, Ligonier, Westmoreland County, Pa.; Jane Bruce Guignard, Twenty-second Street and North College Avenue, Philadelphia, Pa.; Katherine Sophia McKeon Hall, Woman's Medical College, Philadelphia, Pa.; Erle Goodfellow Hawman, 13 South Tenth Street, Reading, Pa.; Rena M. Heilman, Leechburg, Pa.; Louis Benjamin Heiner, 3207 Diamond Street, Philadelphia, Pa.; F. N. Henderson, Gynacean Hospital, 247 North Eighteenth Street, Philadelphia, Pa.; Bernard J. Henney, 419 Chestnut Street, Carnegie, Pa.; George Price Hill, Lansford, Carbon County, Pa.; Nathan H. Hornstine, 325 South Fifth Street, Philadelphia, Pa.; Clarence Willis Hotchkiss, R. F. D. No. 6, Conneautville, Pa.; Jacob Husik, 941 Christian Street, Philadelphia, Pa.; Alexander Spencer Kaufman, 3207 Diamond Street, Philadelphia, Pa.; Frank Keagy, 214 Sixth Avenue, Altoona, Pa.; Russell Henry King, 1327 Sheffield Street, Allegheny, Pa.; Harry E. Klase, 215 Water Street, Danville, Pa.; Florence Myrtle Kline, Leechburg, Armstrong County, Pa.; Harry Butler Knapp, 1809 Wallace Street, Philadelphia, Pa.; Nettie Evans Knapp, 1809 Wallace Street, Philadelphia, Pa.; Henry Adolph Laessle, 5900 Market Street, Philadelphia, Pa.; Harris Hamilton Lane, Pottsville Hospital, Pottsville, Pa.; Henry Cuthbert Lawton, 1706 Summer Street, Philadelphia, Pa.; Frank Alexander Lorenzo, Punxsutawney, Pa.; Eutimio Maselli, Dorset Hotel, E. E. Pittsburgh, Pa.; William J. Matthews, Johnson City, Washington County, Pa.; R. Fait McKenzie, 121 South Eighteenth Street, Philadelphia, Pa.; James J. McNulty, 2717 East York Street, Philadelphia, Pa.; Roy Clark Meals, 202 Lincoln Street, Oil City, Pa.; Herbert Paul Meyers, Markleysburg, Fayette County, Pa.; William C. Minnich, Bedford, Bedford County, Pa.; Rachel Tatnall Moon (under advisement), 4035 Parrish Street, Philadelphia, Pa.; Michael Joseph Noone, State Hospital, Scranton, Pa.; Thomas Edison Oggleve, Dickerson Run, Fayette County, Pa.; Walter Brown Orbin, 3745 Spruce Street, Philadelphia, Pa.; Charles Trumbo Pankhurst, corner Twenty-fourth and Sassafras Streets, Erie, Pa.; John Groh Philips, Onset, R. F. D., Lebanon County, Pa.; Julius Proper, 4370 Cresson Street, Manayunk, Pa.; Mazyck P. Ravenel, 908 Pine Street, Philadelphia, Pa.; Edwin R. Raymaley, Newlonsburg, Westmoreland County, Pa.; Daniel Schaeffer Regar, 123 North Sixteenth Street, Philadelphia, Pa.; Aba Reiss, 115 Pine Street, Philadelphia, Pa.; Jerome B. Rogers, Pottsville Hospital, Pottsville, Pa.; C. L. Santee, Wapwallopen, Luzerne County, Pa.; Arthur Philips Schaefer, 501 Avery Street, Allegheny, Pa.; Reuben Elmer Schall, Ford City, R. F. D. No. 1, Armstrong County, Pa.; Harry Budd Searles, Thompson, Susquehanna County, Pa.; Harry Abraham Shaffer, Williams-town, Dauphin County, Pa.; William Hamilton Shortt, Mercy Hospital, Pittsburgh, Pa.; William J. Steward, Delta, York County, Pa.; William Scott Tinney, Orthopaedic Hospital, Philadelphia, Pa.; George Trotter Tyler, 2114 Pine Street, Philadelphia, Pa.; Ralph Waldo Wakefield, 903 North Forty-first Street, Philadelphia, Pa.; Morris Weinberg, 501 Pine Street, Philadelphia, Pa.; Charles E. Wentz, 6602 Woodland Avenue, Philadelphia, Pa.; Frank R. Wheelock, 884 North Main Street, Scranton, Pa.; Edward Livingstone Whisler, Jollytown, Greene County, Pa.; Albert Woomer, Tamaqua, Schuylkill County, Pa.; Harry Jacob York, Warriorsmark, Pa.; George J. Youell, 2036 East Allegheny Avenue, Philadelphia, Pa.

Pith of Current Literature

PRESSE MEDICALE.

December 17, 1904.

1. Treatment of Cancer of the Tongue. By J. L. FAURE
2. Bacteriological Testing of Catgut, By HALLION and CARRION.

1. **Cancer of the Tongue.**—Faure prefers to divide the extirpation of cancer involving the tongue and the neighboring tissues in the neck into two operations, following the example of Poirier, in the hope of lessening the great mortality which follows attempts to remove all the diseased tissues at once. The first operation is performed wholly in the mouth, the second exclusively in the neck, to remove the glandular and other tissues involved.

2. **Bacteriological Testing of Catgut.**—Hallion and Carrion state that after cleansing catgut of the antiseptic substances used in sterilizing it by treating it two or three times with bouillon, a culture may finally be obtained; whence they conclude that there are living microbes in the catgut which are restrained from development by the presence of a bactericidal substance.

December 21, 1904.

1. Gigantism and Infantilism, By PH. PAGNIEZ.
2. Treatment of Nephritis by "Maceratio Renalina Porci," By MAURICE PAGÉ and DARDELIN.

1. **Gigantism and Infantilism.**—Pagniez in a review of a work on biological studies of giants by Launois and Roy defines gigantism as an anomaly of the growth of the skeleton which produces excessive stature as compared with the average size of his own race, and a morphological and functional lack of harmony characteristic of this morbid state. Infantilism he defines as an anomaly of development characterized by the persistence of morphological characteristics of infancy after the age of puberty. These two conditions can be united in one individual, as in one case described by Launois and Roy.

2. **Treatment of Nephritis by "Maceratio Renalina Porci."**—Pagé and Dardelin report remarkably good success in 18 cases from this treatment. A very fresh kidney from a pig is cut into minute pieces, washed with fresh water to remove the excess of urine, then hashed and pounded into pulp. This pulp is put into 300 grammes of fresh water, to which the physiological proportion of salt, 7.50 to 1000, has been added. It is then allowed to macerate for three hours, stirred occasionally and kept in a cool place to avoid fermentation. The red water of the maceration is divided into three parts to be drunk by the patient during the day.

December 24, 1904.

1. Surgical Treatment of Chronic Nephritis, By LE DENTU.
2. Œsophagosaltary and Œsophagolacrymal Reflexes, By PAUL CARNOT.

1. **Surgical Treatment of Chronic Nephritis.**—Le Dentu gives a brief historical account of the steps which led up to the present operation of de-

capsulization and finishes with extensive quotations from and praises of Dr. Edebohls.

2. **Œsophagolacrymal Reflex.**—Carnot adds to the Œsophagosaltary reflex recently described by Roger one which he calls the Œsophagolacrymal. Frequently the introduction of an Œsophageal sound will provoke an abundant secretion of tears which pour over the cheeks. The lacrymation is not proportionate to the pain, nor does it depend on emotion. It coincides with the salivary secretion and ceases with it, and is likewise due to the titillation of the Œsophagus.

December 28, 1904.

Treatment of Trichomycosis Circinata by the X Rays, By R. SABOURAUD and HENRI NOIRE.

Treatment of Ring Worm of the Scalp With the X Ray.—Sabouraud and Noire report excellent results from this mode of treatment. Among the results are increase in the number of cures without hospital treatment, lessened number of hospital cases, diminution of the length of hospital treatment, and the abandonment of special local provisions for such patients.

ZENTRALBLATT FUER GYNAKOLOG' E

December 17, 1904.

1. Uterine Trauma and Rupture of the Uterus in Pregnancy, By K. BAISCH.
2. Mesenteric Cysts, By W. HAAS.
3. Simple Ulcus Rotundum of the Vagina, By H. THOMSON.
4. Full Term Extrauterine Pregnancy Cured by Operation, By VON LINGEN.

1. **Rupture of the Uterus.**—Baisch reports a case of a woman whose uterus had been perforated by the finger during the removal of a placental polyp. Two years later the woman became pregnant again and in consequence of a placenta prævia, labor was induced. There was such a marked atony of the uterus that the organ was extirpated. At the site of the former perforation, there was a very thin scar which showed on microscopical examination an entire absence of muscular tissue. The author says that this condition accounts for many of the recently reported cases of uterine rupture during pregnancy.

4. **Full Term Extrauterine Pregnancy.**—Von Lingen describes the case of a thirty-seven year old multipara who was found to have a full term extrantrine pregnancy when her abdomen was opened. The fetus was dead, but the sac was uninjured and consisted of the tube which had the form of an hour glass. The peculiar form of the tube had led to a mistake in diagnosis. One part of it contained the placenta, the other the fetus and the umbilical cord. This was connected with the wall of the tube instead of with the placenta, as might have been expected.

December 24, 1904.

1. Audibility of the Heart Sounds in the Fourth and Fifth Months of Pregnancy, By O. SARWEY.
2. Treatment of Climacteric Hæmorrhages, By A. H. QUEISNER.

3. Colpeuryris and the Galvanic Current for Chronic Inversion of the Uterus. By J. VON JAWARSKI.
4. Antiseptic Details, By O. WILLE.

1. **Audibility of Fœtal Heart Sounds.**—Sarwey declares that he and Daederlein could distinctly hear the fœtal heart sounds in one case in the fifteenth week, and in another case, of twins, both hearts could be plainly heard in the sixth month immediately before delivery. After birth (in the latter case) the heart sounds could no longer be detected, although the heart was still beating. This the author ascribes to a change in the action of the heart induced by the birth.

2. **Hæmorrhages of the Menopause.**—Queisser reports two cases of obstinate hæmorrhage in the menopause which resisted all measures of treatment. He then drew the uterus down, split it, and sutured each split half to the incised vaginal mucous membrane. The mucosa of the uterus was then deeply burned with the Paquelin, and the hæmorrhages ceased.

BERLINER KLINISCHE WOCHENSCHRIFT.

December 19, 1904.

1. Advantages and Disadvantages of Ficker's Method of Diagnosticating Typhoid Fever (*To be concluded*), By W. J. GÜTTLER.
2. Digalen, a Substitute for Digitalis Infusions, By E. BIBERGEIL.
3. Five Cases of Tumor of the Central Nervous System, By GRAEFFNER.
4. Hysterical Somnolence, By RÆCKE.
5. Hypochondria, By A. SCHOTT.
6. Psyche and Psychoses (*Concluded*), By P. KRONTHAL.
7. Syphilitic Inoculation of Horses. By PRORKOWSKI.
8. Prognosis and Treatment of Diabetes Mellitus, By DE LA CAMP.

2. **Digalen (Soluble Digitoxin).**—Bibergeil says that this remedy, used largely by Naunyn, allows of accurate dosage, is rapidly absorbed, and has a correspondingly rapid action. It does not upset the stomach as easily as an infusion of digitalis and does not have the cumulative effect of this preparation. It is best taken in vichy or sweet wine after meals in doses of one cubic centimetre.

3. **Tumors of the Central Nervous System.**—Graeffner describes five such cases, two of them cholesteatomatous formations, with descriptions of the autopsies.

4. **Hysterical Somnolence.**—Ræcke records twenty-three cases of this character, ten of which are ordinary cases of somnolence following hysterical attacks. Seven cases are described as those of lethargic attacks, and six are those of hysterical stupor long protracted with periods of delirium and general apathy. The differentiation of this condition from the status epilepticus is to be made in the free intervals and by the history, as well as by the condition of the pupillary and knee reflexes. The differentiation from catatonic stupor is more difficult.

5. **Hypochondria.**—Schott says this term includes many different diseases. It is to be re-

garded as a sign of degeneration and is frequently associated with neurasthenia and hysteria and some forms of insanity. Where hypochondriasis appears in connection with dementia præcox, it deserves an especially careful consideration. Severe hypochondriasis may lead to suicide or to self injury. All peripheral influences of injurious character must be guarded against. Medicines are rarely of value.

8. **Diabetes Mellitus.**—De la Camp regards alleged cures of diabetes as periods of latency. He divides the cases into three groups: the mild, the moderately severe, and the severe. The diabetes accompanying advanced age and that following organic lesions, he considers mild. He regards the albuminuria with hyaline and granular casts, seen in the severe cases, not as signs of nephritis, but as the expression of a chronic functional irritation of the kidneys. For the moderately severe cases, no definite prognosis can be given. The main purpose to be achieved in the treatment of diabetes is the attainment of an absence of sugar in the urine, although the tolerance by some patients of various articles of flour food must be taken into consideration.

RIFORMA MEDICA.

December 14, 1904.

1. Uric Acid in Transudates and Exudates, By FRANCESCO GALDI and GIULIO APPIANI.
2. Contribution to Our Knowledge of the Functions of the Pancreatic Cells (*To be continued*), By ETTORE SAVAGNONE.
3. The Behavior of Pancreatic and Hepatic Secretion in Animals Deprived of the Spleen, By E. GIROLAMO.
4. Anatomical and Experimental Research on Free Bodies in the Serous Cavities (*To be continued*), By LUIGI TOMELLINI.
5. The Spasmodic Syndrome in Infections and Intoxications, By R. MASSALONGO.

1. **Uric Acid in Transudates and Exudates.**—Galdi and Appiani report the following results obtained in investigating the uric acid contents of various effused fluids in the body: Uric acid is an ordinary constituent of effused fluids, and is derived for the most part from the nuclein of the corpuscles, cells, etc., contained in the effusions; it is present in larger amounts in exudates than in transudates. Among the exudates, those of tuberculous origin show the greatest amount of uric acid, provided the exudate is comparatively fresh. The amount in an effusion is usually proportionate to the specific gravity of the fluid in question, to the total amount of nitrogen, and to the amount of proteid material in the sample. In two cases of tuberculous meningitis there was a considerable amount of uric acid in the cerebrospinal fluid, but this fact cannot as yet be utilized because we have no data as to the amount in normal cerebrospinal fluid.

3. **Behavior of the Pancreas and the Liver in Animals Deprived of Spleen.**—Girolamo's researches proved that the pancreatic as well as the hepatic cells continued to functionate without change after the spleen of an animal had been re-

moved. This does not, to his mind, show that the spleen is devoid of influence upon the digestive glands. His researches merely show that the function of the spleen is, perhaps, not very important and that when the spleen has been removed, other structures in the economy take up its function of internal secretion.

5. Increased Tendon Reflexes in Infections.

—Massalongo takes the view that our ideas concerning the significance of increased tendon reflexes in diseases other than affections of the brain, the cord or the nerves, are in sad want of revision. He has paid special attention to the hypertenotonia of infections and intoxications of various kinds, and while making allowances for the individual equation in observations, he draws the following conclusions from his experience in this field: In acute infectious disease (his observations included only typhoid fever and pneumonia) the tendon reflexes are often increased. This is not seen, however, throughout the entire course of these affections and the occurrence of an epileptoid tremor is exceptional. The exaggeration of the reflexes usually is seen at the acme of the disease, and declines during convalescence. When this order is reversed and the reflexes are exaggerated during convalescence the disease is apt to assume a severe form and complications are apt to arise. There is no relation between the exaggeration of reflexes and the fever, and the former has no diagnostic significance whatever. Acute alcoholic, uræmic, and acetonaemic intoxications are followed by increased reflexes, an exception being the acetonaemia of diabetes. In about two thirds of all the cases of chronic affections of the liver and kidneys there are increased reflexes, and these are always associated with other evidences of toxæmia. In cardiac disease, exaggerated reflexes are more apt to be present in the arterial cases than in the endocardial, and in both types they are most apt to occur rather early in the disease. Increased reflexes are an important and often an early diagnostic sign of arteriosclerosis. The author regards this sign as an evidence of intoxication.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

November 27, 1904.

1. Abscess of the Liver, Opening Into the Lung. Importance of Radioscopic Diagnosis. Operation. Recovery. By CARLO QUADRONE.
2. Research on the Hæmolytic and Agglutinating Powers of the Blood Serum in Ankylostomiasis.

By DARIO ROMANI.

3. Contribution to the Study of Gastric Opothrapy, By UMBERTO BACCARANI.
4. Extremely Acute Tuberculous Infection and the Action of the Serum, By E. MARZAGALLI.

1. **Hepatic Abscess.**—Quadrone reports a case of abscess of the liver which ruptured into the lung. He emphasizes the fact that clinically this case resembled one of pulmonary tuberculosis and that the x rays were very useful in diagnosing the true condition of affairs. Exploratory punctures naturally cannot be employed in such deeply situated abscesses of the liver. After the abscess was localized by means of percussion, auscultation, and

the Röntgen rays, in this case, the patient was operated upon under cocaine anæsthesia. An incision 10 cm. in length was made from a point under the angle of the scapula to the paravertebral line, and the pleura was exposed and incised. Adhesions of a firm character were discovered between the lung and the diaphragm, and on separating these the abscess was reached. Proper drainage was established and the discharge soon ceased. The patient made a good recovery.

2. **The Blood in Ankylostomiasis.**—Romani's experiments showed that the blood serum of patients with ankylostomiasis did not possess the property of agglutinating blood cells any more markedly than normal blood serum. On the other hand, the corpuscles of patients with this disease were easily agglutinable. The serum of persons with ankylostomiasis was more markedly hæmolytic to the red cells of rabbits and hens, but not at all hæmolytic toward the red cells of healthy persons, or of persons with severe anæmia from other causes. The serum of persons suffering from ankylostomiasis was found to be markedly toxic, killing rabbits in a short time when small doses of it were injected. In non-fatal doses these injections produced illness and hæmoglobinuria.

3. **Opothrapy in Diseases of the Stomach.**—Baccarani recommends the use of natural gastric juice obtained from the hog in the treatment of gastric diseases of various types. He agrees with Von Noorden that only this natural gastric juice is able to supply the missing constituents in the gastric juice of diseased human stomachs in a perfectly natural manner. The cases of gastric disease which the author treated with more or less success by means of natural gastric juice included nervous and neurasthenic conditions, gastric atony, dilatation of the stomach, chronic gastritis, etc. The good results in neurasthenic gastritis, he thinks, were attributable to the fact that in this class of cases achylia gastrica is so frequently present. In atonic cases a few days' treatment, certainly a week's, showed marked improvement in almost all cases. The patient found that he could resume ordinary diet with impunity, and the gastric contents, when analyzed, showed marked improvements in the amount of free hydrochloric acid found. Patients with dilatation, with chronic gastritis, and with other forms of gastric disease with a distinct anatomical basis, did not show such a marked benefit from the use of natural gastric juice, but this is attributable to the fact that in this class of cases the functions of the gastric mucosa are very greatly impaired.

4. **Action of Antituberculosis Serum.**—Marzagalli, of Maragliano's institute, reports some experimental work which shows the action of the antituberculosis serum made by the Genoese clinician. He produced intense infections and toxæmia in guinea pigs by the intraperitoneal injection of live tubercle bacilli. The animals promptly died. In a second series of animals he injected antituberculosis serum with the bacilli and the toxæmia was arrested, a slow infection taking its place. Even if the bacilli had been injected in large amounts, the

serum sometimes succeeded in arresting the marasmus which followed in these guinea pigs.

December 25, 1904.

1. On Tuberculous Hyperglobulia, By C. TARCHETTI.
2. On Pneumococcus Arthritis, By LEONE SEGRE.
3. The Possibility of Tuberculous Infection Through Preserved Meat, By Dr. TONZIG.
4. On the Reducing Powers of Cerebrospinal Fluid, By A. TONELLO.

1. **Excess of Red Cells in the Blood of Consumptives.**—Tarchetti sharply criticises Mircoli on account of the latter's recent utterances as to the meaning of the excessively large numbers of red cells found in the blood of tuberculous subjects. Mircoli says that the fact that hyperglobulia is found in certain tuberculous persons accounts for the flushed face which often deceives the diagnostician in such patients. He seems to consider the excess of red cells as a favorable sign. Tarchetti calls attention to the fact that, in order to be really a good sign, an excess of red cells must be accompanied by a correspondingly high percentage of hæmoglobin. In tuberculous individuals who have over 5,200,000 red cells to the c.cm., however, the hæmoglobin is found usually very low. One of Mircoli's patients who had a high number of red cells was very pale, so that the theory advanced about the flushed face does not seem to be probable. The fact that the hyperglobulia described by Mircoli was only relative is proved by the observation that these patients for the most part had been subject to repeated hæmoptyses.

3. **Tuberculosis from Preserved Meats.**—Tonzig investigated the possibility of tuberculous infection from what he styles "bagged meats," i. e., sausages, etc., and other forms of meat which are enclosed in bags of animal membranes in the course of preparation. He thinks that *a priori*, the possibility of infection with tuberculosis from this class of meat products is greater than from other kinds of preserved meat, as the sausages of the market contain parts of the animal's body that ordinary meats do not, and thus are more apt to contain tuberculous glands, etc. Again, while the meat ordinarily bought is slaughtered in regularly inspected houses, that which goes into sausages is more apt to be slaughtered clandestinely. Thus the sources of sausage meats are notoriously uncontrollable. In order to determine the possibility of infection the author prepared some salami in which he incorporated the meat of a tuberculous animal, taking care to include portions affected with tuberculous lesions. The salami was prepared according to all the rules of the art, and was kept for a considerable time in order that it may resemble as closely as possible the products bought in the shops. With this he then inoculated two guinea pigs. He concludes from his experiments that infected salami is capable of producing tuberculosis in animals, but that the virulence of the bacillus of tuberculosis disappears in the sausage after a certain time, in this instance after five months, due, perhaps, to the salting and partly to the drying of the sausage.

ROUSSKY VRATCH.

December 18, 1904.

1. The Operation of Total Castration for Cancer in the Male, By V. V. MAXIMOFF.
 2. A Case of Infection of Unknown Origin, By A. M. KOTOVSHTCHIKOFF.
- (N. B.—This is the index number for 1904.)

1. **Emasculation for Cancer.**—Maximoff treats of the operation of "total emasculation" as suggested by Chalot in 1894. This operation consists of the removal of all the male external genitals including the roots of the corpora cavernosa, together with the enucleation of the inguinal glands on one or both sides. The term emasculation for this operation has since then been accepted among French surgeons. The operation itself is of ancient origin, having been used in antiquity in Greece, and in Rome in the sixteenth century in the castration of singers. It is still used to-day in the East in making eunuchs. The first attempt to perform this operation scientifically was made by Annandale in Edinburgh, in 1873, in a case of cancer of the genitals. Since then but few cases have been reported, until Chalot in 1892 described the technics of this operation in detail. The entire literature of the subject now embraces but twenty-three reported cases. The operation as yet has not gained popularity, and it is remarkable that no notice has been taken of it in the writings of German surgeons. The author reports two cases in which he performed total emasculation for cancer. He regards this method as the only suitable and perfectly rational one in those cases in which, not only the penis, but also the scrotum, the testes, etc., are involved in the cancerous process. The operation is not as dangerous as might appear at first sight, and among twenty-five cases thus far reported, there were only two deaths. As yet, however, the paucity of clinical material prevents a definite conclusion as to the dangers of this operation. The operation is well borne, even by patients in advanced years, and the wound heals without reaction with the formation of a linear scar. Maximoff, therefore, thinks that this operation should be employed more frequently than is the case now, in cases in which the simple amputation of the penis, in the nature of things, could not be hoped to accomplish much.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

January 28, 1905.

1. The Nature and Significance of Leucocytosis, By A. MANSFIELD HOLMES.
2. Chronic Arterial Hypertension, By HENRY WIREMAN COOK.

4. Report on the Progress of Actinotherapy During the Past Year, By WILLIAM S. GOTTHEIL.
5. The Dividing Line Between the Neuroses and the Psychoses, By RICHARD DEWEY.
6. Medical Practice in Siberia, By G. B. HASSIN.
7. Clinical and Histological Observations on Sympathetic Ophthalmia, By C. A. VEASEY.
8. The Genesis of Sympathetic Ophthalmitis, By SAMUEL THEORALD.

9. Operative Procedure on the Exciting and Sympathizing Eye in Cases of Sympathetic Ophthalmia, By JOHN E. WEEKS.
10. Fifty Consecutive Cases of Pneumonia Without a Death, By W. J. GALBRAITH.
11. The Most Ancient Medical Practice Laws. The Code of Hammurabi, 2200 B. C., By BAYARD HOLMES.
12. Immunity. Chapter I.

1. **Leucocytosis.**—Holmes asserts that the true significance of the various forms of leucocytes has not been determined. We very imperfectly understand the meaning of the varying percentages of the different forms of white cells. The author believes that it is fairly well established that the small lymphocytes are young cells, and that therefore the number of such young cells is an index of the resisting power of the patient. He has conducted a limited number of observations for the purpose of shedding light upon this subject. From these observations he concludes: (1) That poverty in small lymphocytes exists in connection with a great impairment in body nutrition and cell metabolism. (2) That this condition exists in typhoid fever, tuberculosis, and a variety of debilitated conditions. (3) That it cannot, therefore, be interpreted as being characteristic of any particular disease. (4) That whenever it exists it is always to be considered a potent factor when estimated in connection with the history of the case and the associated clinical symptoms. On the other hand, the lymphocytosis that so frequently accompanies a well marked convalescence, from a condition in which poverty of lymphocytes previously existed, would seem to indicate a condition of increased physiological activity, thus corroborating Virchow's theory of a nutritive and formative hyperacidity of a convalescent organism.

2. **Hypertension.**—Cook concludes: Chronic hypertension may be divided into 4 classes, according to ætiology: (a) arteriosclerotic; (b) cardiac, pulmonary, and cerebral compensatory; (c) toxic; (d) primary. The primary form of hypertension deserves recognition as a distinct disease. Early recognition of the tendency toward a progressive increase in pulse tension should prevent or delay the development of certain forms of cardiovascular and renal disease. In correcting hypertension sodium nitrite has many advantages over nitroglycerin.

5. **Neuroses and Psychoses.**—See this *Journal*, Vol. LXXX, page 89.

10. **Pneumonia.**—Galbraith believes that he has often been able to save life in pneumonia by the treatment he advocates. Two illustrative cases, which give the treatment in detail, are recorded. Quinine and the tincture of the chloride of iron are the "specifics." The iron is given in fifteen minim doses every three hours; the quinine according to the severity of the case. In the first case reported the patient received 90 grains of the drug in the first twenty-four hours, 40 grains in the second, and 45 grains in the third. In the second case the patient received 115 grains in two unequal doses in the first hour after his arrival at the hospital, and a total of 155 grains

in the first twenty-four hours. During resolution quinine must be used with care, as cinchonism may be produced by 5 to 10 grain doses.

BOSTON MEDICAL AND SURGICAL JOURNAL.

January 26, 1905.

1. The Psycholeptic Crises, By Dr. PIERRE JANET.
2. Gastroenterostomy (a Preliminary Note), By JAMES G. MUMFORD.
3. The Prophylaxis of Syphilis, By WILLIAM G. MACDONALD.
4. The Ætiology of Pulmonary Tuberculosis Considered in Relation to Its Therapeutics, By LOUIS F. HIGH.
5. Points Pertaining to the Management of Diabetic and Non-Diabetic Glycosuria, By HEINRICH STERN.

1. **Psycholeptic Crises.**—Janet uses the term psycholeptic crises to denote a series of events which heretofore have not been looked upon as sufficiently well defined to constitute a definite condition. There are a number of patients who suffer from obsessions, impulses, manias of interrogation, tics, and phobias of different sorts in which such manifestations must be looked upon as symptoms of certain profounder disturbances of the feelings, the will, and the perception. If these mental troubles develop slowly and insidiously the author groups such patients under the generic term of psychasthenics. If, on the other hand, the symptoms appear rather stormily and reach a climax with considerable rapidity so that a veritable crisis is reached then such patients should be grouped by themselves and to the characteristic feature of their condition the author gives the name of psycholeptic crisis. A number of cases are reported which serve to make clear the author's views.

2. **Gastroenterostomy.**—Mumford advocates Chaput's operation with this difference: he advises cutting through the pylorus and suturing the cut ends.

3. **Syphilis.**—MacDonald holds that the true prophylaxis of syphilis must depend on education. Education of the infected as well as of the non-infected. The charitable people that support our hospitals should be made to understand that the treatment of acute venereal disease is of more far reaching good than the treatment of broken down syphilitics who have long passed the contagious stage.

4. **Tuberculosis.**—High holds that too much attention has been paid to the exciting cause of pulmonary tuberculosis, and too little to the predisposing factors which are the most important.

AMERICAN MEDICINE.

January 28, 1905.

1. The History and Development of Surgery During the Past Century (*To be continued*), By FREDERIC S. DENNIS.
2. Hepatic Abscess, By NORVELLE WALLACE SHARPE.
3. The Theory and Practice of Percentage Feeding in Infancy, By WILLIAM P. NORTHRUP.
4. Lobar Pneumonia in Infancy, By JOHN LOVETT MORSE.
5. Foreign Bodies in the Oesophagus, By CARL E. BLACK.
6. Strabismus and Its Treatment, By C. M. HARRIS.
7. The Health of the Nation, By WALTER WYMAN.

2. **Hepatic Abscess.**—Sharpe discusses hepatic abscess under the four heads: (1) History. (2) Distribution. (3) Frequency. (4) *Ætiology*. He summarizes his conclusions thus: (1) Hepatic abscess is a pathological condition that has been recognized for many centuries. (2) It is widespread in its occurrence. (3) The so called "tropic liver abscess" occurs most frequently in the hot countries. (4) Sporadic cases of tropic liver abscess are encountered as exotic manifestations in the temperate zones. (5) It is impossible to tabulate definitely a general ratio of frequency of occurrence. (6) Hepatic abscess is at times the result of trauma; usually, however, the result of invasion of the hepatic tissue by various forms of parasites, protozoa, and pyogenic organisms. (7) That form commonly known as "amebic abscess of the liver," is in reality not an abscess, but rather a necrosis and liquefaction of hepatic tissue. When pus is encountered, it is the result of contamination by pyogenic organisms.

4. **Lobar Pneumonia in Infancy.**—Morse describes what he believes to be the typical course of lobar pneumonia in infancy. His description differs somewhat from those usually given. The treatment he recommends follows: (1) In general, the treatment should be hygienic and supportive rather than medicinal. (2) Rest is essential. The patient should be kept in the open air if possible, if this cannot be done the bed should be placed near an open window. The diet must be weak enough not to overtax the sluggish digestion, yet forced feeding may have to be resorted to. (3) The chief therapeutic measures are: For stimulation, when needed, strychnine is best, at times alcohol is of service. For controlling the temperature the fan bath or the cold pack are better borne than sponge or tub baths. Bromides and codeine may be used for the restlessness and oxygen for the cyanosis. There are no specifics.

5. **Foreign Bodies in the *Œsophagus*.**—Black reports two cases of foreign bodies in the *œsophagus* (one a pin and the other a metal washer) in which the diagnosis was confirmed by means of the x ray. The author lays stress on the value of fluoroscopy during operations for the removal of foreign bodies.

6. **Strabismus.**—Harris lays stress on the fact that the fusion faculty is fully developed prior to the seventh year. Therefore if a complete cure of strabismus is desired the efforts to obtain it should be instituted before this period. However, improvement and even cure have occurred up to puberty so that hope should not be abandoned too early. The treatment of the condition necessarily depends on the cause of the strabismus.

MEDICAL NEWS.

January 28, 1905

1. Some Irregular Features of Lobar Pneumonia,
By CHARLES KNAPP LAW.
2. Excision of the Superior Cervical Ganglion of the
Sympathetic for Simple Glaucoma,
By COLMAN W. CUTLER.

3. Homicide by a Boy During a State of Somnambulistic
Automatism,
By T. M. T. McKENNAN and W. K. WALKER
4. Diagnosis of Diseases of the Upper Abdominal Region.
A Plea for Earlier Surgical Interference,
By C. D. HILL.
5. The Relation of Cholin to Epilepsy,
By JULIUS DONATH.
6. Ruptured Ectopic Pregnancy: with Reference to Cases
of the Acute Intraperitoneal Type,
By GROESBECK WALSH.

1. **Pneumonia.**—Law reports a few cases to illustrate some of the irregular features of lobar pneumonia. Attention is called to the following types of cases: (1) Pneumonia followed by pleurisy or empyema; (2) so called central pneumonia; (3) migratory pneumonia, and (4) pneumonia masked by referred pains.

2. **Sympathectomy in Glaucoma.**—Cutler asserts that before sympathectomy can be considered as an established method for the treatment of simple glaucoma, the two following questions must be answered: (1) Is the eye ever injured or the glaucoma aggravated by the operation? (2) Does sympathectomy offer a prospect of sufficiently prolonged relief to justify us in urging it in these desperate cases, either before or in place of iridectomy? The first question will probably eventually be answered in the negative. The objections that have so far been raised concerning the safety of sympathectomy are very inconclusive. The answer to the second question is more in doubt. On the whole, the author is of opinion that in a certain number of cases the excision of the cervical sympathetics is capable of doing good.

4. **Exploratory Laparotomy.**—Hill pleads for a more frequent resort to exploratory section in cases where the ordinary diagnostic methods of the internists fail to clear up and adequately explain abdominal and gastric symptoms. Four cases are reported in detail, which show how confusing and at times misleading certain symptom syndromes may be. Too often, if one waits for the diagnosis to be beyond doubt, the condition of the patient will not warrant surgical intervention.

5. **Cholin and Epilepsy.**—Donath believes that the convulsions of so called idiopathic epilepsy are due to cholin. In his paper he presents the facts on which his beliefs are based. They are of two kinds: (1) Those obtained from the study of the spinal fluid of patients suffering from brain and spinal cord lesions (sixty-four such cases were studied) and, (2) those obtained through experiments upon animals.

6. **Ectopic Pregnancy.**—Walsh wishes to emphasize but a single point, that is, that in operations for acute rupture of the sac of an extrauterine pregnancy no time should be wasted in attempting to remove the blood clots. They are sterile, and if left behind will help nourish the patient.

MEDICAL RECORD.

January 28, 1905.

1. Pathological Characters, Diagnosis, and Epidemiology of Bubonic Plague, By MARK JOHNSTON WHITE.
2. The Limitations of the Office Treatment of Rectal Diseases, By CHARLES B. KELSEY.
3. The Use and Abuse of Curettage of the Uterus, By E. K. BROWD.
4. Gluttony or "Food Poisoning" as a Cause of Symptomatic Epileptic Convulsions, By WILLIAM P. SPATLING.
5. Marked Mental Improvement Following Operation for Depressed Fracture of Skull, By B. VAN D. HEDGES.
6. Geheimrath Dr. Dettweiler. Eulogy Pronounced on the Occasion of the First Anniversary of His Death, By S. A. KNOPF.

1. **Plague.**—White has studied plague in California, Honolulu, and Hong Kong. His paper is formal in character and covers the chief points relating to the disease. Three types of plague are recognized: the lymphadenal, pneumonic, and septic. Each of these varieties is discussed in succession. Other points covered by the paper are: (1) Plague in insects, rats, and other animals; (2) clinical microscopy and cultures; (3) pathological diagnosis; (4) bacteriological diagnosis, and (5) epidemiology. The principal transmitters of infection from port to port are (1) imports likely to be eaten or infected by insects and rats; (2) persons, wearing apparel, and bedding; (3) scavenger, and possibly, granary insects; (4) rats and other animals.

2. **Rectal Diseases.**—Kelsey is not in favor of doing very extensive operations for the relief of rectal diseases in the office. It must be granted that many quite severe operations may be done painlessly under local anæsthesia, but subsequent shock and pain may be marked. In general, it may be said that local anæsthesia in no way reduces the gravity of a rectal operation and that the preparatory and after-treatment should be as thorough as in cases subjected to a general anæsthetic.

3. **Curettage of the Uterus.**—Browd attempts to define the kind of cases which are suitable for treatment by means of a uterine curettage. Experts disagree, so that the most general conclusion that can be drawn from the author's paper is that at times very serious injury follows the use of the curette and that therefore the operation should be looked upon as one to be done by the expert only. Four cases are reported which illustrate how much damage can be done through faulty judgment or defective technics.

4. **Gluttony and Epilepsy.**—Spatling within the past two years has had under observation some eighteen or twenty cases of symptomatic epileptic convulsions which occurred after gross overindulgence in eating and drinking. Such cases are usually amenable to treatment, provided the patient is able to control his vicious appetite. If he is not, he may develop into a confirmed epileptic of the so called habit type. The author is of the opinion that the cases to which he calls attention should be grouped alone, forming thus a distinct type of disease.

INTERNATIONAL JOURNAL OF SURGERY

January, 1905.

1. Practical Gynæcology, By SELLMAN.
2. The Relation of Deep Linear Strictures of Large Calibre to Disturbances of Micturition and Recurrent Posterior Urethral Inflammation, By LYDSTON.
3. The Essential Remedies in Emergency Surgery, By ABBOTT.
4. Practical Treatment of Diseases of the Eye, By COOKE.
5. The Mastoid Operation in Infants and Children, By JARECKY.

2. **The Relation of Deep Linear Strictures of Large Calibre to Disturbances of Micturition and Recurrent Posterior Urethral Inflammation.**—Lydston draws the following conclusions from his investigations and experience: 1. A relatively contracted or actually constricted condition of the membranous urethra, and of the bulbomembranous junction often exists in cases in which instruments of considerable size can be introduced into the bladder with more or less freedom. 2. This condition may cause recurring attacks of inflammation of the deep urethra and its annexa, including the prostate. 3. When instrumentation is painful, and there is spasmodic obstruction to the passage of instruments with subsequent inflammation, frequency of micturition, and chill and fever the condition described in this paper usually exists. 4. In the majority of cases of spasmodic stricture there is an organic foundation in the form of a narrowing, chronic inflammation, and hyperæsthesia of the membranous urethra. 5. A properly constructed bulb will demonstrate such strictures. 6. The severity of the resulting symptoms is usually out of proportion to the degree of contraction, the most intractable form of stricture in this location being one of large calibre located in the bulbomembranous junction. 7. The only satisfactory treatment is perineal section, with free division of all points of narrowing and complete dilatation of the deep urethra and vesical neck, followed by more or less prolonged rest and drainage.

BRITISH MEDICAL JOURNAL.

January 14, 1905.

1. Arteriosclerosis, By J. BARR.
2. The Effect of Salts of Potassium, Ammonium, and Bile Salts Upon Blood Pressure, By A. EDMUNDS.
3. The Sanatorium Treatment of Phthisis. Is It Worth While? By W. B. RANSOM.
4. The Influence of Rainy Winds, Soil, Poverty, and General Death Rate on the Phthisis Death Rate in Exeter, 1892 to 1901, By W. GORDON.
5. Results of Four Years' Sanatorium Work in the Treatment of Phthisis, By R. THURNAM and C. E. WHEELER.
6. Further Report on the Treatment of Phthisis by Iodoform Infusion, By T. W. DEWLE.
7. The Treatment of Hæmoptysis, By C. H. CATTLE.
8. Operative Methods—New and Old—in Tuberculosis of the Knee Joint, By SIR W. THOMSON.
9. Tuberculosis and Mortality in Childhood, By W. P. S. BRANSON.

1. **Arteriosclerosis.**—Barr, in the term arteriosclerosis, includes not merely the thickening of the small arteries and arterioles, but also the

atheroma and calcareous degeneration in the large arteries. It results from the presence in the blood of deleterious substances of varying nature: some increase the arterial tone by stimulating the unstriated muscle fibre directly, or indirectly through the nervous mechanism, while others have a depressor action. As an evidence of the presence of such bodies the author has found the freezing point of the blood lowered in all well marked cases of arteriosclerosis. Long continued straining of the arterial coats impairs the elasticity and nutrition of the vessels, and leads to chronic inflammation of the intima, with subendothelial cellular hyperplasia. This cell proliferation appears as white patches, which break down, leading to ulceration and aneurysm, or lime salts are deposited, leading to calcification. The arch of the aorta suffers most in this process. In smaller arteries, not subject to strain, there is hypertrophy of the muscular coat and subendothelial hyperplasia. It may be that there is an excess of adrenalin secreted in this case, leading to high tension and its evil results.

3, 4, 5, 6, 7, 8, 9. **Tuberculosis.**—Ransom discusses the sanatorium treatment of pulmonary tuberculosis, and the questions as to whether our expectations have been justified, and this costly movement worth the while. He concludes that in sanatoriums, as now managed, from one fourth to one third the patients regain their working capacity for at least four years, and that those who survive that period will live longer. Most of the relapses occur in the first two years after discharge. The earlier the patients are sent, the larger the number of recoveries. The home or out patient treatment of the consumptive poor is a failure: but undoubtedly a sequence of treatment in a hospital and a convalescent home does good.

Gordon has studied the effect of various influences on the phthisis death rate in Exeter and from statistics claims to show that in that city: 1. The streets whose roadways are swept by the prevalent rainy winds—S. W., W., N. W.—suffer more from phthisis than those whose roadways are sheltered. 2. The streets built on relatively impervious soil tend to suffer more than those on relatively pervious soil. 3. The streets inhabited by the poor suffer more than those inhabited by the well to do. 4. General death rate, apart from poverty, does not seem to affect the phthisis death rate. 5. Exposure to rainy wind exerts a greater influence than soil or poverty. 6. The influence of rainy wind appears to be direct upon the people exposed to it, not, as some have suggested, indirect, either through closure of doors or windows or through wet driven into walls.

Thurnam and Wheeler report the results obtained at the Sanatorium of Nordrach-upon-Mendip, where 289 cases of pulmonary tuberculosis have been treated within the past four years. *Severe* cases, 56 died within twelve months of beginning treatment: percentage, 30.6; 23 died within two years: 12.7; 30 were followed for two years, and then lost sight of; 39 are in fair health, but are unable to do any heavy work; per cent., 21.3; 35 patients are in enjoyment of

normal health and at work; per cent. (cured) 19.1. *Moderately Severe.* 84 cases in all: 5.8 per cent. died within two years: 22.6 per cent. alive, but lost sight of: 13 per cent. in fair health: 58.3 per cent. cured. *Slight.* 22 cases in all. None dead: 4.5 per cent. alive two years after: 4.5 per cent. in fair health: 90.9 per cent. cured. The above figures emphasize the desirability of early treatment. The total percentage of cures was 35.9.

Dewar gives further results obtained with his method of treatment of pulmonary tuberculosis by means of the intravenous injection of iodoform dissolved in ether. He now adds 40 per cent. of liquid paraffin to the solution, making it less irritating to the veins. Nine illustrative cases are cited, in all of which improvement took place, five of the cases showing arrest of the disease. All the cases were severe.

Cattle says that even in the mildest cases of hæmoptysis the patient should be placed at rest in bed. For an ordinary hæmorrhage of moderate amount, a quarter of a grain of morphine should be given hypodermically: the only exception is where the bleeding is so profuse as to suffocate the patient, and here he should be encouraged to cough up the blood. Only syncope can stop the bleeding in such cases. Free purgation by means of salines is a useful measure, but should be omitted in severe cases. Calcium chloride in twenty grain doses is said to increase the coagulability of the blood and thus check bleeding. An icebag to the chest is rarely required. Adrenalin should not be given: it does constrict the blood vessels, but also brings about a greatly increased blood pressure. The inhalation of nitrite of amyl is a much more rational plan of treatment.

Thomson reviews the old and new operative methods of treatment of tuberculosis of the knee joint, and holds that the elder procedure, excision, is still to be preferred. It is definite, comparatively short in treatment, very free from serious after complications and quickly restores a patient to active life. Erosion is not definite, after-treatment is long, complications are always imminent and frequently develop, the patient is not speedily restored to active life, and, lastly, when the surgeon ceases to look for a movable joint, the whole position is surrendered to excision.

Branson has studied the influence of tuberculosis on mortality in childhood, and concludes as follows: 1. That among poor children in London tuberculosis is absolutely most fatal during the first two years of life, but, relatively to all other causes of death, becomes progressively more fatal until the fourth year. 2. That there is no specific relation between measles and whooping cough on the one hand and tuberculosis on the other. 3. That catarrhal lesions of mucous membranes are the paramount predisposing causes of tuberculosis in early life, and measles and whooping cough are potent in this regard only through the catarrhs accompanying them. 4. That about fifty per cent. of children dying of tuberculosis in childhood have had neither measles nor whooping

cough. 5. That while the infection of tuberculosis in childhood is mostly air borne, primary infection of the abdomen is by no means a rarity.

LANCET

January 14, 1905.

1. Emergencies in Ophthalmic Practice. By M. RAMSAY.
2. The X Ray Treatment of Leucæmia. Report of a Case with Abstract of the Literature.
By J. C. G. LEDINGHAM and R. G. MCKERRON.
3. The Influence of Rainy Winds on Phthisis (*Continued*).
By W. GORDON.
4. Some Clinical Observations with New Remedies.
By N. TIRARD.
By D. BLAIE.
5. Hæmorrhagic Typhoid Fever.
6. Injuries to the Eye by Penetrating Foreign Bodies and the Results After Magnet Operations.
By L. BUCHANAN.

1. **Ophthalmic Emergencies.**—Ramsay offers some points of guidance in the commoner emergencies in ophthalmic practice. When a wound implicates the margin of the eyelid the edges must be brought accurately together, in order to prevent inversion of cilia and scratching the cornea with the movements of the lids. In wounds of the inner canthus there is a risk that the tear passages be wounded, and closed up by the subsequent cicatrization, and the patient suffer from persistent watery eye. In extensive lacerations of the eyelids, always make sure that the globe itself is not implicated. Observance of this precaution will often prevent infection of the globe and loss of the eye. The swelling, hæmorrhage, and pain may be so great as to necessitate the use of an anæsthetic. In eye injuries the pain and distress are often in inverse proportion to the gravity of the injury. In such cases the application of two per cent. cocaine solution permits of examination, and appropriate treatment. Burns are the most disastrous of all injuries to the conjunctiva, especially those due to chemical irritants, and the prognosis must be very guarded. Symblepharon will certainly occur in every case where the retrotarsal fold of conjunctiva has been destroyed. After the eye has been burned, it should be irrigated thoroughly with any bland fluid, and then a few drops of cocaine in castor oil instilled. An iced compress should then be applied, and kept on for at least twelve hours. Leeches and morphine may be required to relieve the pain. Contusion of the eyeball leads to subconjunctival or intraocular hæmorrhage. Unless there is structural damage, the dimness of vision due to shock soon disappears. In intraocular hæmorrhage sight is always interfered with. Atropine should be instilled, and iced compresses applied. An ophthalmoscopic examination should be made as soon as possible in order to determine the extent of the structural damage. Subconjunctival hæmorrhage sometimes follows whooping cough in children. When the bones at the inner side of the canthus are fractured, emphysema of the eyelids may occur, with epistaxis. Here a firmly applied bandage is essential. If there is total loss of sight the optic nerve has probably been injured. Sudden permanent blindness without a history of injury is usually the re-

sult of embolism of the central artery of the retina, but it must not be confused with the dim vision of glaucoma or the transitory blindness of migraine. Glaucoma comes on suddenly with intense pain and inflammation of the eyes, but these symptoms may be temporarily masked by a so called "bilious" attack. If there is any complaint of swelling of the eyeballs the globes should be palpated to ascertain if the ocular tension is increased. A dilated pupil, a shallow anterior chamber, and a stony hard eyeball, are absolutely characteristic. Atropine must never be used. Instead, instil eserine, apply leeches to the temples, and fomentations to the eyes. If the pain is not relieved in a few hours, the tension may be reduced by opening the eyeball at the corneal angle. And finally it may be necessary to perform iridectomy.

2. **Leucæmia.**—Ledingham and McKerron report a case of splenomyelogenous leucæmia in a boy aged 11 years. The spleen was enormously enlarged, and the leucocytes numbered 234,000 per cubic millimetre. Arsenic was tried, but could not be borne. He remained under observation for a year and a half with little or no change. Following the suggestion of Senn treatment with the x rays was then begun, the rays being applied over the splenic tumor and the lower epiphyses of the femora. The exposures lasted about ten minutes, and were given every other day. No disagreeable sensations were complained of. In six weeks the leucocyte count came down gradually from 222,000 per cubic millimetre to 23,000, after which time it oscillated around 30,000. The red cells varied greatly, a count of over 5,000,000 being noted several times. The myelocytic leucocytes showed no tendency to disappear, and the blood picture in stained specimens remained abnormal. The splenic tumor became softer and diminished in size, and the patient's weight increased materially. The authors have analyzed the literature of the treatment of leucæmia by x rays and find that with one or two exceptions, all the cases of myelogenous leucæmia have been greatly benefited, both objectively and subjectively. In the later stages of fibrosis of a splenic tumor, but little decrease in size can be expected. It is suggested that the x rays act by destroying the lecithin of the leucocytes and thus cause their death.

3. **Rainy Winds in Phthisis.**—Gordon, having shown in the first part of his article that rainy winds have an extremely deleterious effect on the course and prevalence of phthisis, here considers the relative strength of the other influences known or supposed to affect phthisis, as follows: Soil, altitude, temperature, dry winds, especially when dusty, rainfall, density of population, insantiation, poverty, occupation, race, preventive measures, other forms of tubercle, other respiratory diseases, and malaria. And he concludes from statistics and other lines of reasoning that exposure to rainy winds has a greater effect in increasing the phthisis death rate than any other influences, except those of extreme difference of race and injurious occupation.

Letters to the Editor.

THE COLLEGE OF MEDICINE OF THE UNIVERSITY OF NEBRASKA.

LINCOLN, NEB., January 20, 1905.

To the Editor,

Sir: My attention has only just been called to one item in the report on the Curricula of American Medical Colleges, printed in your issues of July 23 and 30, 1904. In the College of Medicine of the University of Nebraska 780 hours are not devoted to orthopædic surgery. This represents the time devoted to general and orthopædic surgery together. As the record in the report passes an unmerited criticism upon our curriculum, I beg you will give the correction the same prominence which was accorded to this report.

HENRY B. WARD.

MEDICAL MEN AND PATENTS.

103 STATE STREET,

CHICAGO, January 20, 1905.

To the Editor,

Sir: My attention was recently called to Dr. Lydston's admirable editorial entitled *Should the Physician Patent His Ideas?* which appeared in your issue of September 3, 1904. I fully indorse the several claims and deductions set forth therein, but wish to call attention to one point of importance which the writer omitted.

To my mind one of the strongest arguments in favor of the patenting of surgical instruments is that the inventor may so control instruments of his design that defective and inferior patterns will not be made and sold under his name and without his consent. At present it is the custom for each manufacturer to turn out such new instrument as he desires without consulting the inventor thereof, and frequently without being first provided with a correct model, and, in fact, he may even introduce some modification of his own. In this way there is often a material difference found between the productions of different instrument makers when their respective patterns of some one given instrument are compared, and the changes from the original are most often disadvantageous, and may destroy some of the most important and salient features of the instrument, so that it could not be used with satisfaction by the inventor himself. Hence the sale of such defective products may reflect discredit upon him, and also constitute an injustice to the innocent purchaser. I have frequently seen instruments purporting to be of my design, and sold under my name, which did not possess the essential characteristics of the original, and which I could not myself employ with any degree of satisfaction.

At present the first maker of a new instrument asks for it at the start a much higher price than it will command at a later date, for he wants to be reimbursed for the extra cost of the first lot before competitors copy it and thus reduce the price, which may eventually, through competition, be made so low as not to warrant good

workmanship. In this way the first purchasers are charged too high a price, while the greater number of later purchasers will get an article of inferior grade. My nasal speculum, which has been extensively sold, is a good example to illustrate this state of affairs.

On the other hand, if surgical instruments were patented the reputation of the inventor would not suffer by defective styles of his instruments being sold, as each instrument would be made by only one manufacturer, whose aim would be to have it furnished correct in all ways, and as he would for several years, during the life of the patent, control such instrument, he would be willing to assume the extra expense incurred in the making of the first lot, so a fair price would from the start be adopted, thus granting early purchasers the advantage of the fixed price, and guaranteeing subsequent purchasers an instrument of correct pattern. Furthermore, in the case of a delicate instrument where such care is desirable, each lot turned out could be inspected by the inventor. In this way the interests of the profession would be benefited, and for these reasons, as well as for the several other reasons cited by Dr. Lydston, it should not be considered unethical to patent instruments.

There is, though, unfortunately another and commercial reason why this plan cannot be generally followed, and that is owing to the comparatively great expense required in the taking out of a patent, which, including attorney's fees, approximates \$75, and this is a much greater sum than the prospective sales of a large majority of new instruments would warrant.

EDWIN PYNCHON.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of November 23, 1904.

The President, Dr. ROLAND G. CURTIN, in the chair.

Skigraph of an Old Ununited Fracture of the Scaphoid Bone, Illustrating the Value of the X Ray in the Diagnosis of Such Fractures.—Dr. L. J. HAMMOND reported the following case: A young medical student had consulted him for a condition of pain in his right wrist, from which he had been suffering for more than two years. There was no tenderness or any visible sign of inflammation, and it was only when the wrist was abducted that the pain was intense. The condition had been variously diagnosed as rheumatism, sprain, tuberculous periostitis, and tenonitis. Treatment for these various conditions had given no relief. The x ray revealed a fracture of the scaphoid bone, the fragments of which were united by a very loose fibrous connection. The interposed fibrous tissue was removed and the fragments of bone were wired together. Perfect apposition of the fragments was secured and they were held together by two small silver wire sutures. There was perfect restoration of all the wrist movements with entire absence of pain.

An interesting point was the fact that, while the patient recalled having fallen with the hand outstretched and abducted, no immediate symptoms of pain, swelling, or ecchymosis were sufficiently pronounced to demand surgical aid. Dr. Hammond said that experience in the surgical out patient departments of city hospitals showed the frequency of unrecognized fractures of the bones of the wrist and ankle joints. The only treatment was to secure bony union, which could only be done by securing perfect apposition, either by wiring or any other of the mechanical means for this purpose. He believed wiring to be by far the most reliable procedure.

Dr. CHARLES LESTER LEONARD referred to the obscure character of these fractures, which could be demonstrated in no other way than by the x ray.

Dr. HAMMOND agreed with Dr. Leonard that fractures like that in his case were not rare, and were sure to be overlooked and the condition treated as a sprain or some constitutional fault. The object of the paper was to show that fracture in this type of case should be thought of and a diagnosis made by means of the x ray.

Typhoid Fever in Philadelphia.—Dr. RANDOLPH FAIRES, in the consideration of this subject, said that typhoid fever did not exist in Philadelphia to such an alarming extent as the general public had been given to believe. The apparently large proportion of the disease in the city he attributed to three conditions: Errors in diagnosis, cases contracted elsewhere, and duplicate cases. He enumerated sixteen diseases which might be mistaken for typhoid fever. No case should be reported to the board of health as typhoid fever unless a Widal reaction had been taken and in addition the urine, feces, and catarrhal secretions examined. Special care should be taken in examining the liver and spleen, and in noting the course of the temperature, the nature of the pulse, and the amount and kind of stupor, as well as the nervous symptoms present. Stress should be laid upon the rose spots, and a blood count should be made. With the municipal improvements of cleaner streets, better surface drainage and perfect deep drainage, the abolition of cesspools, houses constructed with better scientific ventilation, careful disinfection of everything whereby typhoid might be transmitted, and extreme vigilance on the part of the health authorities in reference to impure milk, adulterated foods, impure water, and a constant instruction to the general public in reference to those foods by which typhoid was often conveyed, such as raw oysters, lettuce, overripe and unclean fruits, etc., it was reasonable to suppose there would come a time when very few cases of typhoid fever, if any, would exist in Philadelphia.

Dr. EDWARD MARTIN, director of the Bureau of Public Health, observed that statistics showed a certain amount of transfer of typhoid fever from one case to another, and that the reason for reporting the cases, so far as the public health was concerned, was to prevent this direct transfer and to take precautions against a local epidemic. In most of the cases of typhoid in the well to do the community was properly protected, but in the cases

seen by the corps of assistants to the Bureau of Health the importance of a report was very great. The bureau had rather have a report of a case which was not typhoid, and look it up, than to have the case unreported, with a possible spread of the contagion. The question of the disinfection of the dejecta he regarded as a difficult one, and thought we should not be indifferent to the people who got water below our pollutions. In the walking cases the urinary secretions might remain for a week a prolific source of infection. The Bureau of Health had made a statistical study of wells and cesspools, and had been astonished to find upward of one hundred in such juxtaposition that the water must be infected. He regarded the water supply as the main source of infection, and felt that Philadelphia would still be a typhoid cursed city until it had a filtered water supply.

Dr. FAIRES said that many of the cases were reported too quickly, but that the remedy was difficult, since the assistant inspectors of the health department were not allowed to interfere with the family physician. It was therefore manifestly the duty of the family physician to be especially careful in his diagnosis. While it was possible to ascertain the exact number of cases outside of the city, and the duplicate cases, it was not possible to estimate the cases of error in diagnosis.

Trachoma Successfully Treated With the X Ray.—Dr. W. S. NEWCOMET and Dr. J. P. KRALL reported this case and exhibited the patient, who was a girl of eighteen. She had been subjected to all the operations for the cure of the condition, but without success. Treatment was begun in July, 1903, and continued until the first of the year. The inflammatory reaction was so intense that it was thought better to abandon the treatment. Later, however, it was found that she could count fingers at close range. The cornea of the eye that had been treated was entirely clear and only with special illumination could there be seen fine blood vessels. The eye not treated with the x ray showed all the symptoms that the treated eye had formerly exhibited. The condition had been present since infancy, and the girl had been unable to see across a room. Treatment was given every other day for five minutes for about six weeks, when the burn developed and treatment was withheld. The result, Dr. Newcomet believed, was due to the accidental burn produced in the course of treatment.

Dr. JAY F. SCHAMBERG referred to a case of trachoma seen in the Polyclinic Hospital, less pronounced than the case exhibited in the vascular injection of the cornea, but having a tremendous growth of vegetative excrescences upon the conjunctivæ. The man had received about twenty treatments. The growths had almost entirely disappeared in both eyes, and the conjunctivæ were fast approaching a normal condition. In technique, the eye was exposed by means of a clamp, the upper lid was everted, and the clamps were held by weights.

Dr. GEORGE E. PFAHLER referred to the paper of Dr. Mayo, of London, and his results in treatment of trachoma by the x ray, and especially to the value of the method in clearing up the cornea. He did not understand that any burns had been

produced in the cases of Dr. Mayo. The face at first was covered with a mask, but later no precaution was taken. The tube, a soft one, was placed at about nine inches from the patient, and the treatments were from three to five minutes in length. Personally, Dr. Pfahler had had no experience with the method.

Dr. LEONARD regarded the case as of much interest, both from the aspect of the ophthalmologist and from that of the x ray worker. The condition still present in one eye, which had been symptomatically cured in the other, he thought showed a marked illustration of the possibilities of the x ray in chronic conditions about the eye. The value of the method, he believed, depended, not upon the production of a burn, but upon a specific action of the x ray upon the autolytic ferments contained within the cells themselves. The x ray, he stated, was not a cure-all, but an agency which assisted Nature by stimulating to action the elements contained within the cells.

Dr. M. K. KASSABIAN agreed with Dr. Leonard regarding the stimulating and irritating action of the x rays upon the tissues, but believed, further, that there was a germicidal or inhibitory action upon the germ. In technique, he covered the Crookes tube with a dark cloth and darkened the room, preventing injury to the patient from the light, because of the excessive photophobia. He attached the everted eyelids by adhesive plaster to the forehead. He had had four cases in the Philadelphia Hospital, two acute and two chronic. In the acute cases there had been severe photophobia and lacrymation, and they were improved after four or five exposures.

Dr. NEWCOMET said that he had been impressed, when in London, with what might be called the carelessness with which the cases there were treated; one half of the men used little or no protection in the treatment, and one man used only wet gauze. Dr. Newcomet used a shield, and as much as possible avoided handling the eyes.

Dr. KRALL agreed with Dr. Leonard in regarding the effect of treatment as due to the stimulation of some of the ferments, and not to a germicidal action.

Meeting of December 28, 1904.

The First Vice-President, Dr. B. FRANKLIN STAHL, in the chair.

Food Preservatives and Food Adulteration.—Dr. H. W. WILEY, chief of the Bureau of Chemistry of the United States Department of Agriculture (by invitation), read a paper on this subject. He said that the necessity of preserving food in some way had been recognized since man emerged from his savage state. The development of the science of chemistry had placed in the hands of the manufacturer the means of preserving food before unknown and the means of matching foods in tints and colors. He believed that the education of the public in regard to artificial coloring of foods was quite as effective as legislation. After the 2nd of February, he said, the food law would require that all food products entering this country artificially colored should bear a label so stating. The material for coloring need not be declared, except in the one case

of sulphate of copper. His advice to food makers was to cease using colors, and especially if the coloring was under suspicion of any kind. Concerning antiseptics in relation to foods, he thought the rights of the consumer were paramount. He believed that there never should be antiseptic admitted to foods, except when absolutely necessary, unless the consumer ordered it for himself. There was, he thought, a legitimate use of sulphurous acid, as employed in the fumigation of dried fruits and the burning of the sulphur match in wine barrels, which method had come down from antiquity, but when it was used, as at the present time, in enormous excess for preserving a poor wine and putting on the market a new wine before it was ripened, he declared its use to be unpardonable. He believed that the application of the principle of honesty would cover all the needs of a food law. Were Dr. Wiley to write a food law, it would require that every food product be marked and be exactly what it was said to be.

Defects in Pennsylvania Food Legislation.—WILLIAM W. SMITHERS, ESQ. (by invitation), read a paper with this title. He said that the laws upon this subject now being enforced in Pennsylvania were not the expression of the wishes of the people, and that they resulted in unnecessary interference with manufacturers and merchants. He advocated the repeal of the act of 1895 and the enactment of laws based upon the preservation of health and protection against fraud. In conclusion, he stated his belief that the office of Dairy and Food Commissioner was unconstitutional, the existing food statutes were imperfect and open to many just complaints, and every effort should be made to secure reasonable and adequate legislation upon this important subject.

The Evaluation of Evidence as to the Pharmacological Action of Food Preservatives.—Dr. THOMAS LUTHER COLEY, in this paper, stated that as an economic principle it was apparent that a nation of eighty million people could not be fed from the farm to the table or from the local abattoir to the table, and there arose the complex problem of transportation of food in an edible condition. The use of chemical preservatives therefore had become a necessity. Dr. Coley went over the grounds upon which these were used and reviewed the chief objections against their use. The dangers arising from reputedly prepared food to which preservatives had been added were as nothing in comparison with the dangers from foods that had undergone putrefactive changes. A problem of such importance should be settled by medical men, and not in courts of law with a lay jury. Legislative enactments should not be made in advance of scientific knowledge. There must be disabuse of the mind of the criminality of intent on the part of reputable manufacturers, and a sharp line should be drawn between adulteration and food preservation. The question to be decided was that of the action of very minute amounts of food preservatives over a protracted period. In order to illustrate the faulty interpretations from research work undertaken on a wrong basis, Dr. Coley

cited the papers of Pfeiffer, Kionka, and Harrington dealing with sulphite of sodium. In all these studies the amount of the drug used had been higher than that employed for preservative purposes; too great quantities of meat were fed to the animals and no variety of diet was allowed. Further, the animals were confined and of questionable health in the beginning of the experiments, and the deductions of these authors were not warranted, so far as the use of sulphite of sodium as a food preservative was concerned.

Book Notices.

Essentials of Medical Chemistry, Organic and Inorganic. Containing also questions of Medical Physics, Chemical Philosophy, Analytic Processes, Toxicology, etc. Prepared Especially for Students of Medicine. By LAWRENCE WOLFF, M. D., formerly Demonstrator of Chemistry, Jefferson Medical College; Physician to the German Hospital of Philadelphia, etc. Sixth Edition, Thoroughly Revised. By A. FERRE WITMER, Ph. G., formerly Assistant Demonstrator of Physiology, University of Pennsylvania; Neurologist to the Out-Patient Department of the Hospital for Ruptured and Crippled, New York City. Philadelphia, New York, London: W. B. Saunders & Company, 1904. Pp. 225. (Cloth, \$1.00.)

Whatever opinions may be held regarding the value of the system of teaching provided in question compends, no doubt can exist of the popularity of books of this class. The one before us has demonstrated its practical usefulness by passing through five editions. Dr. Witmer's sixth revision contains much new matter pertaining to recent important discoveries in physics and inorganic chemistry, and is calculated to be of considerable service to those for whom it is intended.

A Textbook of Physiological Chemistry. By OLOF HAMMARSTEN, Professor of Medical and Physiological Chemistry in the University of Upsala. Authorized Translation from the Author's Enlarged and Revised Fifth German Edition by JOHN A. MANDEL, Sc. D., Professor of Chemistry and Physics and of Physiological Chemistry in the New York University and Bellevue Hospital Medical College. Fourth Edition, First Thousand. New York: John Wiley & Sons; London: Chapman & Hall, Limited, 1904. Pp. viii-703. Cloth, \$4.00.)

The rapid progress of physiological chemistry during the last five years has necessitated a thorough revision of most of the chapters of this well known textbook, and it has been improved in other respects, chiefly by the omission of certain parts containing statements which have been proved untenable by more recent research. While the volume has not been brought into smaller compass by such elimination, too great an increase in its size has been prevented. The literature of physiological chemistry becomes more specialized every year, and the descriptions of chemical methods which were treated of more fully in preceding editions are

somewhat curtailed in this, only those methods which are of first importance for the physician and student being described at length. The general plan of the book remains unaltered, the author's addenda having been incorporated into the text. The fact that the book has passed through so many editions in such a comparatively short period, coupled with the knowledge of its very general adoption as a textbook in teaching institutions, affords ample evidence of its enduring usefulness.

V. Internationaler Dermatologen-Kongress abgehalten in Berlin vom 12 to 17 September, 1904. Verhandlungen und Berichte herausgegeben von Sanitätsrat Dr. O. ROSENTHAL, General-Sekretär. I. Band. Berlin: August Hirschwald, 1904. Pp. v-394.

While rather disappointing to any one seeking for new ideas in regard to leprosy, this work is rather interesting to any one seeking for the latest statistics as to geographical distribution, measures taken for isolation, treatment, etc. The American report, by Dr. Isadore Dyer, is especially painstaking and shows a woeful lack of precautions against the spread of the disease by our neighbor Mexico.

Official News.

Public Health and Marine Hospital Service Health Report:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending January 27, 1905:

Smallpox—United States.

Place.	Date.	Cases.	Deaths.
Colorado—Garfield County.....	Dec. 1-31.....	11	
Colorado—Lake County.....	Dec. 1-31.....	5	
Colorado—Larimer County.....	Dec. 1-31.....	18	
Colorado—Las Animas.....	Dec. 1-31.....	1	
Colorado—Weld County.....	Dec. 1-31.....	1	
Dist. Columbia—Washington.....	Jan. 8-21.....	4	
Florida—Jacksonville.....	Jan. 8-14.....	1	
Illinois—Chicago.....	Jan. 15-21.....	18	1
Louisiana—New Orleans.....	Jan. 15-21.....	13	
Michigan—Detroit.....	Jan. 15-21.....	2	
Missouri—St. Louis.....	Jan. 15-21.....	24	1
Tennessee—Memphis.....	Jan. 15-21.....	10	
Tennessee—Nashville.....	Jan. 15-21.....	3	
Wisconsin—Milwaukee.....	Jan. 15-21.....	6	

Smallpox—Foreign.

Austria-Hungary—Prague.....	Dec. 25-31.....	5	
Brazil—Pernambuco.....	Dec. 2-15.....		85
Brazil—Rio de Janeiro.....	Dec. 26-Jan. 1.....	73	23

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending January 25, 1905.

EARLE, B. H., Assistant Surgeon. Granted leave of absence for three days from January 21, 1905. Granted extension of leave of absence for four days from January 25th.

FOSTER, S. B., Acting Assistant Surgeon. Granted leave of absence for twelve days from January 24th.

GOODMAN, F. S., Pharmacist. Granted leave of absence for seven days from January 24th.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending January 28, 1905:

BRECHEMIN, LOUIS, JR., First Lieutenant and Assistant Surgeon. Left Fort Baker, Cal., on thirty days' leave of absence, from January 17, 1905.

FORD, CLYDE S., First Lieutenant and Assistant Surgeon. Ordered to proceed from Fort Barrancas to Ormond, Florida, on public business.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending January 28, 1905:

BAKER, M. W., Assistant Surgeon. Detached from the *Brooklyn* and ordered to the Naval Hospital, San Juan, P. R.

CRANDALL, R. P., Surgeon. Detached from the *New Orleans* and ordered home to await orders.

CURL, H. C., Passed Assistant Surgeon. Detached from duty with the Isthmian Canal Commission on the Isthmus of Panama and ordered to the *Boston*.

ELY, C. F., Assistant Surgeon. Detached from the Naval Academy and ordered to duty with the Marine Detachment on the Isthmus of Panama, sailing from New York on January 31, 1905.

GEIGER, A. J., Assistant Surgeon. Detached from the *Prairie* and ordered to the Naval Station, Port Royal, S. C., for temporary duty.

GUTHRIE, J. A., Passed Assistant Surgeon. Ordered to the *Dirie*, sailing from New York on or about February 4, 1905.

GROVE, W. B., Surgeon. Ordered to the Naval Hospital, Chelsea, Mass.

HENNEBERGER, L. G., Medical Inspector. Detached from the *Olympia* and ordered home to await orders.

LEYS, J. F., Passed Assistant Surgeon. Detached from the Naval Station, Guam, L. I., and ordered home to await orders via the *Solace*.

ODELL, K. E., Passed Assistant Surgeon. Ordered to the Naval Hospital, New York, N. Y.

STEEP, J., Assistant Surgeon. Ordered to the *Constellation* and to additional duty at the Naval Training Station, Newport, R. I.

TAYLOR, J. L., Assistant Surgeon. Appointed an assistant surgeon, with the rank of lieutenant, from December 17, 1904.

WILSON, G. B., Surgeon. Detached from the Naval Hospital, Chelsea, Mass., and ordered to the *Olympia*.

Births, Marriages, and Deaths

Married.

BARBEE—FERGUSON.—In Bozeman, Montana, on Wednesday, January 4th, Dr. Charles Minton Barbee and Miss Olla Ferguson.

DANFORTH—MATTICE.—In Gilboa, N. Y., on Wednesday, January 18th, Dr. Edward Danforth and Miss Helen E. Mattice.

LEMKE—HAMMOND.—In Baltimore, Maryland, on Thursday, January 19th, Dr. George Lemke and Miss Annie T. Hammond.

NEUWIRTH—MAGENHEIMER.—In St. Charles, Missouri, on Monday, January 2nd, Dr. Joseph Neuwirth and Miss Annie Magenheimer.

PAINE—FRYE.—In St. Louis, Missouri, on Sunday, January 22nd, Dr. G. F. Paine and Mrs. Dora Frye.

SANDERS—BENNETT.—In Jefferson, Georgia, on Tuesday, January 3rd, Dr. Laetus Sanders and Miss Mary Bennett.

WYRICK—FISCHER.—In St. Louis, Missouri, on Tuesday, December 27th, Mr. Taylor Blow Wyrick and Miss Stella Ethel Fischer, daughter of Dr. Joseph A. Fischer.

Died.

BLINN.—In Chicago, Illinois, on Friday, January 20th, Dr. Odella Blinn, in the sixty-first year of her age.

CANTRELLE.—In New Orleans, Louisiana, on Thursday, January 19th, Dr. J. A. Cantrelle.

CORY.—In Washington, D. C., on Friday, January 27th, Dr. B. F. Cory, in the eighty-sixth year of his age.

Craven.—In Philadelphia, on Thursday, January 10th, Dr. Edward R. Craven, in the eighty-third year of his age.

DUMOND.—In New York, on Saturday, January 21st, Dr. Cornelius J. Dumond, in the sixty-ninth year of his age.

ELIOT.—In New York, on Monday, January 23rd, Anna, wife of Dr. Ellsworth Eliot, in the eightieth year of her age.

ENSMINGER.—In Chicago, Illinois, on Wednesday, January 18th, Dr. W. H. Enslinger, in the sixty-first year of his age.

FABER.—In St. Louis, Missouri, on Thursday, January 12th, Paulina, wife of Dr. John E. Faber, in the sixty-sixth year of her age.

FOUDRIAT.—In New Orleans, Louisiana, on Saturday, January 14th, Dr. L. E. Foudriat, in the sixty-fourth year of his age.

HARWOOD.—In Atwood, Tennessee, on Saturday, January 14th, Dr. J. W. Harwood, in the sixty-sixth year of his age.

HELLYER.—In Philadelphia, on Monday, January 16th, Dr. Edwin Hellyer.

HERRING.—In Lancaster, Kentucky, on Tuesday, January 17th, Dr. H. C. Herring, in the seventy-third year of his age.

HITT.—In Atlanta, Georgia, on Tuesday, January 17th, Dr. Virginia G. Hitt, in the sixty-fourth year of his age.

HUNT.—In Newtonville, Massachusetts, on Friday, January 20th, Dr. Otis Eugene Hunt, in the eighty-third year of his age.

O'NEILL.—In San Francisco de Malabon, Philippine Islands, on Tuesday, January 24th, Dr. Joseph A. O'Neill, United States Army.

Miscellany.

Contributions to the Study of Spontaneous Rupture of the Aorta.—Tolot and Sarvonat, in the *Revue de médecine*, for November 10, 1904, offer the following conclusions: In spontaneous rupture of the aorta the blood may penetrate into the pericardium through the external coat of the vessel which has been separated and saturated with blood, but not perforated. Rupture frequently occurs at the site of atheromatous patches, but often at other points, even though there may be many distinct areas of atheroma in the vessel. It would therefore appear that the rôle of atheroma is not very important, and may even have no significance at all in the pathogenesis of rupture of the aorta. The action of syphilis has not yet been sufficiently investigated, though its effect upon the middle coat of the aorta is well known. New investigations may give increased significance to its presence.

The New Treatment of Cancer.—Doyen, in the *Revue de chirurgie*, for November 10, 1904, refers to the method of preparation of the fluids which he uses in the treatment of cancer and to the results which this mode of treatment has given him thus far. Of 242 cases of cancer of every variety, treated by his method there have been 42 in which there were no symptoms of recurrence for about four years. There are 46 cases which are still under observation, in most of which the prospects are favorable. In 20 cases no report as to the result has been received, and in 128 cases no benefit has resulted, either because the treatment was begun when the disease was too far advanced or because it was interrupted contrary to the wishes of the surgeon, before it could have produced any permanent effect. In 6 cases death occurred from accidental causes at a time when the cure of the cancerous disease seemed probable.

Referring to the indications in the author's method of treating cancer, he considers that the cases which should be subjected to treatment are:

1. All cases of tumors which are positively malignant in which the disease is still localized and which according to the experience of the past are almost certain to have a recurrence of the disease should an operation be performed.
2. Cases of cancer in which the disease is still localized, but in which complete removal is impossible on account of complications with vital organs.
3. Cases which are inoperable on account of the extent of the disease, but in which vital organs have not as yet been attacked, for example, cancer of the breast *en cuirasse*. It is, of course, apparent that no treatment whatsoever can restore ad integrum essential organs, the tissue of which has been entirely destroyed. The possibility of inoculating those who are threatened with cancerous disease, either from heredity or from suspicious general or local conditions, is suggested, and it is believed that immunity could thus be secured at least for a long period. The discussion of this paper before the French congress of surgery elicited opinions which were unfavorable in the main to Doyen's hopes and contentions.

Nephritis Symptomatology and Diagnosis.—Eshner, in *Medicine*, for December, 1904, recalls the facts that the excretion of water, certain products of retrogressive metamorphosis, and of certain substances which may be introduced into the body in various ways constitute the function of the kidneys, while there is no reason for believing that they have an internal secretion. In health the kidneys prevent the passage of the albumin of the blood into the urine. The factors which cause nephritis are infective or toxic and when this inflammatory process occurs it probably involves both kidneys. Under favoring conditions the tissues of the affected organs may be restored to their normal condition. Clinically three varieties of nephritis may be considered, acute parenchymatous, chronic parenchymatous, and chronic interstitial. The distinctive feature in all of them is the presence of albumin and tube casts in the urine, both factors ranging under certain well recognized conditions. The albumin may be serum albumen, serum globulin, nuclealbumen, albumose, or peptone.

Tube casts result from coagulation of the products of disintegration of the epithelial cells of the uriniferous tubules.

Albumin is abnormal when present repeatedly or continuously in large quantity. Tube casts are probably never present under wholly normal conditions. (Edema is probably due to the action on the blood vessels of the causes which underlie the inflammation of the kidneys. With oedema and transudation into serous cavities there may also be inflammation of serous membranes.

In parenchymatous nephritis the quantity of urine diminishes with the intensity of the inflammation, in interstitial nephritis the quantity is increased until the disease approaches its termination. The specific gravity and the intensity of color of the urine bear an inverse relation to the quantity voided. Hypertrophy of the heart and increased vascular tension are almost always present in chronic nephritis. Retinitis is one of the distinctive features of nephritis, and amaurosis may result. Anæmia is a constant feature of parenchymatous nephritis, the number of red cells and the percentage of hæmoglobin being diminished, and the leucocytes remaining unchanged. The most important complication is uræmia and it may be present with either the acute or the chronic disease.

Albumin and tube casts may be absent and nephritis still be present; again they may be present and be due to some cause other than nephritis. Systematic examination of the urine should always be made. In acute parenchymatous nephritis there is a history of infection, intoxication, or exposure to cold. There may be a chill, drowsy, diminished urine, elevation of temperature, acceleration of pulse and respiration, headache, nausea, and vomiting. In chronic parenchymatous nephritis there is a history of a previous attack, diminution of urine, possible uræmia, cardiac hypertrophy, and increased arterial tension. Recovery is rare though the disease may continue for years. In chronic interstitial nephritis the invasion may not have been noted, the urine is increased, the heart hypertrophied and arterial tension increased. Dropsy and uræmia may be late symptoms, and there may be hemorrhages from mucous membranes.

Parturition Observed Upon the Isolated Uterus.—Kurdinowsky, in *Fortschritte der Medizin*, for October 10, 1904, reports interesting physiological and pharmacological experiments with reference to the contractions of the uterus. Having performed abdominal section on a number of rabbits he injected the uterus, from the aorta, with Locke's fluid, so that the blood was completely removed. He then extirpated the uterus with the annexa and broad ligaments and placed them in a chamber moistened with Locke's fluid. Notwithstanding the fact that the blood had been completely withdrawn from the uterus it could be excited by irritation even on the second and third days after its removal, producing contractions which followed a definite curve. One such uterus remained active forty-nine hours and forty minutes. On two occasions he observed the entire act of parturition from beginning to end on the pregnant uteri of rabbits. The contraction waves began at the tubal end of the cornua and progressed toward the corpus, the result being the gradual removal of the connection between the ovum and the uterine wall. After it was entirely separated the ovum was slowly but uninterruptedly projected by means of continued contractions through the cornu and toward the corpus. The same procedure was observed in the second cornu with the second ovum, until both ova were present within the corpus. Then one of the cornua contracted more forcibly and more frequently than before until its entire contents had been projected into the corpus. The next step consisted in energetic contractions of the broad ligament which surrounds the corpus upon all sides. These circular contractions transverse to the uterus squeezed the contents of the corpus into the vagina. As soon as an ovum had been transferred to the vagina the contractions of the broad ligament ceased. As the second ovum entered the vagina it pushed the first one forward. The round ligaments also contracted in a circular manner from above downward during the progress of the ovum through the corpus and vagina.

From these demonstrations it is possible to say with definiteness that a uterus entirely removed from the influence of the cerebrospinal nervous system is competent to perform the function of parturition; in other words, that it has an entirely independent action. During the emptying of the uterus the fetuses died as a rule, after violent contractions, but in one case a fetus lived about fifty minutes, and for thirty-five minutes it lived outside the uterus.

The isolated uterus is therefore adapted for observation of the physiology of this organ, and gives evidence of its automatic action. Thermal and chemical irritants increase its contractions and often produce contractions of a tetanic character. Electrical irritation on the other hand seemed to have very little influence.

The contractions of the broad ligaments are of particular interest. The question of the local innervation of the uterus is thus seen to be a matter of the greatest importance.

The uterine horn contracts peripherally upon the uterus and is independent of the narrowing of the blood vessels. Narcotic poisons, such as

chloral and alcohol, have little influence upon the isolated uterus. Clinical studies upon this subject in relation to the act of parturition will be of the greatest importance.

The Prognosis of Epilepsy.—Turner, in the *Edinburgh Medical Journal*, for December, 1904, states that Herpin in 1852 first gave detailed attention to this phase of the question of epilepsy. His percentage of cures was much greater than that of more recent writers upon this subject.

It does not seem that the use of the bromides has improved the prognosis to any great extent. Sex has little to do with the question of prognosis. More males than females show arrest of seizures, but there are also cases of epilepsy in males than in females. There is a greater percentage of epileptic dementia in females, while in males the most frequent mental condition is impairment of memory and blunting of the higher mental faculties.

With regard to heredity, there is as great a probability of arrest of the disease in those who have a family history of epilepsy as in those who have not. General improvement is more likely to occur in those who have no hereditary taint in this direction. If there is hereditary tendency to epilepsy or insanity, it increases the probability that the disease will be permanent and that dementia will result.

Epilepsy commencing in infancy or childhood is most likely to be persistent. The type which begins during puberty is the most favorable one. Adult epilepsy is unfavorable, senile epilepsy is tractable.

The earlier a case is brought under treatment the greater is the probability of improvement. There is a progressive tendency for the disease to become confirmed the longer it lasts without definite treatment. The longer the interval between the attacks the greater the prospect of arrest or improvement. If attacks are of daily or weekly occurrence the chances of recovery are not good, and there is grave prospect of mental impairment. The major attacks are more influenced by drugs than the minor ones. Mental disturbance is more frequent with *petit mal* than with *grand mal*, but is the more profound when the two varieties are combined.

Remissions are a characteristic feature of this disease. When the disease begins in infancy it may remit during childhood and recur at puberty. Several years may intervene between the first and the second attacks. Remissions sometimes occur under the influence of bromides, the disease returning if the drug is omitted. A remission may be terminated by a blow upon the head, a fall, childbirth, an inflammatory disease, etc.

In general terms it may be said that the disease is curable, but there is great difference of opinion as to the period of remission which constitutes a cure. The author does not consider any case as cured in which the seizures have not been in abeyance nine years. In his analysis of a large number of cases he has found that in 10.2 per cent. only was there a remission for that period. If improvement is to occur at all as the result of treatment it will be likely to occur within a year from the time that treatment is begun.

THE DIAGNOSIS OF TUMORS OF THE CEREBELLUM AND THE CEREBELLOPONTILE ANGLE, ESPECIALLY WITH REFERENCE TO THEIR SURGICAL REMOVAL.

By CHARLES K. MILLS, M. D.,

PHILADELPHIA,

PROFESSOR OF NEUROLOGY IN THE UNIVERSITY OF PENNSYLVANIA; NEUROLOGIST TO THE PHILADELPHIA HOSPITAL.

In time it is probable that as regards tumors of the cerebrum, especially those located on its lateral aspect anywhere from the cephalic tip to the occipital pole, success both in diagnosis and in operative treatment will reach from twenty-five to fifty per cent. By success is meant the exact localization and removal of tumors, the operation from the surgical point of view being entirely successful, and partially so from the point of view of the removal of the disease. Supposing that fifty per cent. of such cases are reached, ten to fifteen per cent. will not recur, or at least not in periods varying from three to ten years. In the remainder the painful and distressing general symptoms of brain tumor will be removed for a time, the neoplasms recurring in some cases after an interval, while in others the cases may terminate fatally. Life in most instances will not only be prolonged, but will be made much more comfortable. Tumors of the mesal aspect and of the base of the brain will always be uncertain in result, although an occasional growth situated on the orbital or temporal surface may be successfully reached. We must, therefore, after growths located on the lateral aspect of the cerebrum, look to tumors of the cerebellum and cerebellopontile angle for our next highest percentage of successes in spite of the hitherto unsatisfactory, and in some instances even disheartening, results of surgical procedure.

The surgical aspects of the subject, including the methods and results of operation and statistical details, will be fully considered by Dr. Frazier;

but as I have had much experience in observing operations on the cerebellum, I may be permitted, in introducing a discussion of the symptomatology and diagnosis of cerebellar tumors, to say a few words about the accessible sites for operation.

Although an operation is difficult and often unsuccessful, tumors in certain cerebellar locations may be regarded as "operable." These are: 1. Tumors situated wholly or in large part in one lateral lobe. 2. Tumors situated upon or in part invading the vermis or middle lobe. 3. Tumors of the cerebellooblongatopontile angle. Only in the case of a tumor located in large part in one lateral lobe of the cerebellum does an operation afford a really good chance for success, but in rare cases both tumors of the vermis and of the cerebellobulbar angle can be reached and removed.

With regard to tumors of the vermis or middle lobe, the writer has had no personal experience with operative procedure. I believe, however, that in some instances tumors resting upon or even invading the vermis may be reached and removed. The operation in this case should include an opening on each side of the median line, and possibly the ligation of the sinus and the removal of the bone intervening between the two openings. Such an operation is feasible, although, perhaps, difficult.

The diagnosis of the existence of a tumor in the cerebellum is as a rule comparatively easy, but to exactly locate and infer the size and extensions of such a growth is a more difficult task; and yet when operation for removal of the tumor is under discussion, the focal diagnosis becomes of paramount importance.

In the first place, brief consideration will be given to general symptomatology and diagnosis. In a large majority of cases of cerebellar neoplasm the well known general symptoms of brain tumor, namely, headache, nausea, and vomiting, optic neuritis, and vertigo, are present and are of pronounced character.

While the headache in many cases is intense, and in some even agonizing, in others it is of

moderate severity and in rare instances, of which a few have come under my observation, it may be entirely absent or it may not appear until late in the course of the disease. In about half the cases the headache is referred to the back of the head or to this region, and at the same time to other parts, as to the nape of the neck and various portions of the cranial vault. Frontal headache of a severe type is occasionally observed in cases of cerebellar tumor, just as in some instances of frontal neoplasm the pain is most intense or is present alone in the occipital region. Too much stress therefore must not be placed on the site of the pain.

Nausea and vomiting are symptoms of frequent occurrence, although they occasionally disappear for long periods in the progress of a case. The mechanism of these symptoms is much the same as that of the vertigo due to dural irritation, which will presently be considered.

With regard to optic neuritis and its consequences, it is only necessary to say that our experience is similar to that of others who have found this sign of intracranial tumor more constant in cerebellar tumors than in those located in almost any other region of the brain. The development of the choked disc or optic neuritis is often rapid, or at least goes on at a much accelerated pace after it has reached a certain moderate height. The choking of the disc is extreme, and hæmorrhages are numerous. Unless operative interference checks the progress of the inflammation, blindness speedily occurs, and this is one of the reasons for early surgical procedure, even when the case has not a hopeful outlook as regards removal of the growth.

Dr. de Schweinitz, in his paper on the ocular phenomena of tumors of the cerebellum, to which the reader is referred, fully considers the ophthalmoscopic appearances and conditions in this affection. Nearly all the cases included in the series from which the inferences contained in this paper are drawn were seen by him.

The vertigo which is so frequently a general symptom of brain tumor, wherever situated, is usually due to irritation of branches of the trigeminal nerve, which are distributed near the inner surface of the dura, the irritation of the fifth nerve being reflected to the bulbar nuclei of this nerve and thence to the pneumogastric nucleus. This is usually one of the causes of the vertigo in tumors of the cerebellum when the growth is connected with the dura, which is not the rule. In other cases it should be regarded as a focal rather than as a general symptom of cerebellar tumor, as it is caused by the disturbing

influence exerted by the tumor upon the cerebellovestibular apparatus.

A distinction must always be made between cerebellar vertigo and cerebellar ataxia, although the two are often so interblended that this is not easily done. Subjective vertigo is common, the patient usually describing it as a feeling of dizziness. Both subjective and objective vertigo may be extreme and exhibit striking characteristics which indicate their focal origin. In a case recorded by Osborne,¹ for example, in which a large glioma was situated in the right cerebellar lobe, the patient was unable to sit up, and could not turn her head without having an attack of vertigo. The dizziness was relieved by complete rest in bed, but came on again with less frequency, although with much severity. The patient would always lie with her head to the right, saying that she became dizzy if it were turned to the left. Later epileptoid seizures took the place of the vertigo.

I shall discuss next the strictly focal symptoms of tumor of the cerebellum.

Nystagmus is one of the most frequent symptoms of cerebellar tumor. It is present in growths variously situated in the cerebellum or jointly in the cerebellum and adjacent parts, as for instance in the middle lobe, in one lateral lobe when the neoplasm is close to its junction with the middle lobe, in the prepuncle or jointly in this and the oblongata. A tumor or other lesion confined to the flocculus is said to give rise to nystagmus. The nystagmus of cerebellar or cerebello-pontile disease may be of various types, as regards the manner of its occurrence, its direction, and the rapidity or slowness of the oscillations. It may be present when the eyes are quiet and looking straight forward, or under these circumstances it may be absent, but capable of being elicited by having the eyes turned either to the right or to the left, or upward or downward. It may be horizontal or vertical or both in the same case. The movements are sometimes rapid and fine or slow and comparatively coarse. In the case of Bruce referred to later in this paper, the nystagmoid movements, which were present in all positions, were increased on lateral movements; on looking to the right the oscillations were slower and larger. They were of intermediate rapidity and extent in looking upward or downward. It has been suggested that the nystagmus can be brought out when it is not present, or that it is greater if present, when the eyes are turned toward the side of the lesion, a

¹ Osborne, O. T., *Journal of Nervous and Mental Disease*, N. Y., Vol. xxix, October, 1902.

view which was supported by one case of cerebellar abscess recorded by Spiller,² but was not confirmed by a case of cerebellar tumor reported by this writer in the same paper. We have not been able as yet to make any inferences of localizing value from a study of cerebellar nystagmus, although it would seem probable that in a case of destructive lesion affecting the cerebellovestibular tract, the nystagmus would be greater when the eyes were directed toward the side of the tumor. I shall refer presently to the views of Bruce on this subject.

The question of the existence of a true paresis or paralysis as the result of a cerebellar lesion is one that has been discussed both by physiologists and clinicians. That a general paralysis has been observed as both the result of experimental lesions of the cerebellum and of cerebellar hæmorrhage, tumor, or abscess in man cannot be doubted, but in many cases at least this symptom is due to the effect of the lesion on neighboring parts, as for instance on the pyramidal tract or tracts. Asthenia or muscular weakness is, however, a real cerebellar symptom. Sometimes it is overlooked, the symptoms which are dependent upon this weakness being attributed to incoordination or other cause.

In a valuable paper by Grainger Stewart and Gibson³ these writers report at length their observations with regard to the state of voluntary movements in the five patients which form the basis of their paper. In all of these cases the patients exhibited weakness of the legs, as tested not only in standing and walking, but also by movements in bed. Weakness of the spinal muscles was present in three cases. Niemeyer, Hughlings Jackson, and Risien Russell, who are cited by Stewart and Gibson, have shown that paresis or weakness of the spinal or trunkal muscles results from cerebellar lesion. Jackson believes that destructive lesion of the vermis causes paralysis or paresis, most marked in the muscles of the trunk, next in the lower extremities, and least in the upper limbs. Discussing the weakness of the spinal muscles, Stewart and Gibson referred to the relief which is sometimes afforded by the use of crutches. In several cases of tumor of the cerebellum I have observed distinct evidences of weakness of the muscles supporting the vertebral column. It is probable that some of the difficulty experienced by the patients in maintaining their equilibrium, and some of the tendency to fall or pitch to one side or the other, are

dependent in part at least upon asthenia or paresis rather than entirely upon incoordination. In Case V of the series appended to this article and that of Dr. Frazier the general musculature was flaccid, and the head showed a tendency to fall backwards or a little to one side, apparently because of weakness of the supporting muscles of the neck.

Batten⁴ has called attention to what he believes to be the diagnostic value of the position of the head in cases of cerebellar disease. He refers to the fact that Risien Russell has observed in animals after ablation of a cerebellar hemisphere, that the head sinks on the shoulder on the side on which the operation is performed, the eyes being deviated to the same side and upward, and the chin to the opposite side. The spinal column is concave on the side of the ablation. Batten observed a case of tubercle of the right lateral lobe of the cerebellum in which the patient's head sank towards the left shoulder, the face looked upwards toward the right and the chin rotated to the right. The spinal column, as in animals experimented upon, was concave towards the same side. The same symptoms have been observed by Batten in hydrocephalus.

At a meeting of the St. Louis Medical Society on September 17, 1904, at which some remarks were made by the writer on the diagnosis of cerebellar tumors, Dr. J. J. Putnam, of Boston, spoke in the discussion of a case in which this symptom or some modification of it was present.

The symptom known as hemiasynergia, first described by Babinski,⁵ who believes it to be present on the side on which a cerebellar tumor or other lesion exists, has been sought for in all cases of cerebellar tumor recently observed, but so far it has not been found a reliable sign of cerebellar disease. This symptom is brought out in the lower extremity by having the patient, with his eyes shut, flex the leg fully on the thigh and the thigh on the abdomen, and then require him to extend the limb to its full length. If the extension is done normally, the leg and thigh movements are performed synchronously or rather synergically, but the leg is first straightened out and then the entire limb is brought to a horizontal position by a second movement. I have noted the presence of this symptom in several cases, but in some instances when shown at one examination it would fail to be elicited at another in the same extremity. It was present on the side of the lesion on several occasions when one of the cases recorded in connection with this paper was examined. On other occasions

the limb was extended synergically. Shortly after eliciting the sign at an examination made in the ward of the hospital, this patient was taken before the class in the amphitheatre and hemiasynergia could not be demonstrated. In the case of Spiller, several times referred to in this paper, it was present on the side of the tumor and was observed by the writer.

As is said elsewhere, a tumor circumscribed to the outer part of one lateral lobe may not give rise to any symptoms, or at least, to any of diagnostic value. Excepting cases of this kind, all tumors of the cerebellum cause, or at least may cause, incoordination. Some grade of ataxia has been present in all cases of cerebellar tumor studied by me. The degree and character of this ataxia have varied greatly in different cases. It is always present in tumors of the vermis, unless it may be in cases to which Bruce has referred, in which a symmetrical distribution and slow development of the tumor prevent the appearance of the ataxia. The Romberg symptom is practically always present, but it may differ greatly in degree. It differs from the static ataxia of a case of advanced tabes in that it is much less markedly increased by closing the eyes. The sway is, however, usually somewhat increased with the eyes shut; but unless the cerebellar disease is much advanced, the patient will often be able to keep relatively steady on his feet for a considerable time.

The cerebellar gait is, as it has often been described, a staggering or titubating gait. The steps are more irregular in their lateral and vertical amplitude than those of a tabetic, unless the disease in the latter case is advanced to a point where the patient can barely maintain himself in the erect position while walking. The pose and the gait of a case of cerebellar tumor, or of other lesions of the cerebellum, are due not alone to incoordination. Vertigo and muscular weakness, specially weakness of the muscles attached to the spinal column, as well as incoordination, act in their production.

The direction in which the patient sways on standing or tends to pitch or fall in walking may be a matter of much diagnostic importance. Often it plays a considerable part in the discussion of the site of operation. According to Starr⁶ the staggering in four fifths of the cases of cerebellar tumor is away from the side of the lesion. This is not my own experience. In those cases coming under my observation in which either necropsy or operation has revealed the tumor, the swaying or staggering has been of-

tener toward the side of the lesion than toward the opposite. In two cases reported by Schede,⁷ because the patient tended to fall toward the left, the tumor was located on the right, and in both cases an operation showed that it was situated on the left. In one of these cases the tumor could have been successfully removed. In several cases of which the writer has personal knowledge the focal diagnosis was wrong as to the side on which the operation was performed, although we should certainly have the data to enable us to avoid this mistake—one which is not made by skillful diagnosticians with regard to any other region of the brain, unless it is occasionally the prefrontal.

In discussing this question of the side of the cerebellum on which a lesion is situated, as determined by a study of the symptomatology of the case, it should first be borne in mind that one half of the cerebellum exerts its influence on the same side of the body as itself, its action on the spinal cord being direct and not crossed. Bruce has so well presented the facts which should guide us in determining the side on which a tumor is situated that I shall take the liberty of presenting his views, founded as they are upon both close pathological and clinical investigation.

The limits of a paper intended to be chiefly clinical will not permit me to present at length the facts and arguments of this article, one of the most valuable contributions to cerebellar localization of recent years. I shall, however, summarize a few of its most salient points.

The cortex of the vermis contains the termini of at least six different tracts from the spinal cord. Bruce⁸ holds that the direct cerebellar tract and the anterolateral tract of Gowers, which go to the cortex of the middle lobe, are afferent to the cerebellum. One tract from the nucleus of Deiters passes downwards into the anterolateral column of the spinal cord; another tract sends fibres to both the sixth and the third nuclei. The first of these tracts, which has been given the name of the vestibulospinal tract, has been traced to the lowest part of the thoracic cord, and gives off fibres to the anterior cornua, these distributions being to the same side of the spinal cord as the nucleus. The third connection of Deiters's nucleus is with the roof nucleus of the middle lobe of the cerebellum. This tract is efferent. The cortex of the middle lobe of the cerebellum is connected by sagittal fibres with the roof nuclei.

The dentate nucleus is the chief seat of origin of the peduncle, fibres passing by way of the

⁷ Schede, *Deutsche med. Wochenschr.*, July, 1900, No. 30.

⁶ Starr, M. A., *Organic Nervous Diseases*, 1903, p. 612.

prepeduncle to the red nucleus and the thalamus. This nucleus being partly in the middle and partly in the lateral lobes, a tumor situated deeply enough to invade it or fibres passing from it to the prepeduncle will cause disturbance of equilibrium of a peculiar kind.

"We may expect," says Bruce, "disturbances of equilibrium to be produced by symmetrical lesions situated within an area bounded by the intracerebellar path of the two inferior peduncles, of the two superior peduncles, and the dentate nuclei, in which the latter arise. This area contains the middle lobe (superior and inferior vermis, the roof nuclei, and the sagittal fibres connecting the latter with the cortex), and the cerebellovestibular tracts from the roof nuclei to the nucleus of Deiters. Lesions within this area may produce no such disturbances, provided they are symmetrically situated with reference to the mesial plane, and especially if their growth is so slow that compensation is established *pari passu* with the disturbances they may tend to cause. On the other hand, lesions situated in the lateral lobes may produce no disturbance of equilibrium, provided they are situated entirely external to the intracerebellar paths of the upper and lower peduncles and of the nucleus dentatus (area of possible latency). If, however, these structures are interfered with, either by pressure or by direct involvement, then the characteristic symptoms of cerebellar disease will be produced, and will depend in their character and amount on the nature and extent of this interference. If the cerebellovestibular tract, or Deiters's nucleus, be injured, then the usual stimuli will not pass either to the anterior cornua of the cord or to the sixth (fourth) or third nuclei. Hence may result the weakness of the same side, the tendency to fall to that side, the impairment of the conjugate deviation to that side, the tendency of both eyes to be directed to the opposite side, and the lateral nystagmus which occurs, especially when the eyes are directed towards the same."

In what is here said the tumor is regarded as acting destructively, but if it acts as an irritative lesion it may cause rigidity or spasm of the same side, with a tendency to fall toward the opposite side, the eyes being turned to the same side by irritation of the sixth nucleus of that side.

It may be asked, How is one to determine whether the tumor is acting as an irritative or a destructive lesion? The answer to this should be found in a study of the spastic or non-spastic condition of the limbs of one side, and a careful consideration of the side to which the eyes are turned.

In the case of Dr. Spiller, which was operated on by Dr. Frazier, the patient tended to always pitch or fall toward the right, and the tumor was found at necropsy on this side. The same was true of several cases observed by me.

Bruce,⁹ in a second paper, has recorded a case of cerebellar tumor in which the principles of localization as taught in his first paper, were successfully put into practice. In this case the ataxic, asthenic, and ocular symptoms pointed to the left side, the patient pitching towards the left. The tumor was found on this side.

The diagnosis of a tumor confined to the middle lobe is relatively easy, and has already been indicated in the references just made to the two articles by Bruce.

In one of three cases recorded by Preston¹⁰ a tumor of the vermis, probably "operable," was revealed by necropsy. This case exhibited abolition of the muscular sense (?) in both arms and legs, with inability to stand or walk and a tendency to always fall backward, never to either side. Necropsy showed a bilobar tumor compressing the vermis like a saddle in its inferior part. It also exerted some compression upon the quadrigeminum; it apparently had attachments to the callosum, falx, and tentorium.

While all the facts necessary for final decision regarding the effects on the brain of the direction of movement of lesions situated in different parts of the vermis are not yet at our command, it is probable, as usually taught, that destruction of the cephalic portion of the vermis will cause a tendency to fall forwards and irritation a tendency to fall in the opposite direction; while destruction of the caudal portion will cause a tendency to fall backwards, and irritation will bring about the muscular adjustment necessary to counteract this tendency. It has already been shown that destructive lesion involving the lateral lobe and vermis or that part of the lateral lobe containing portions of the cerebellovestibular and cerebellospinal mechanisms causes a tendency to sway or fall to the side of the lesion an irritative lesion bringing about the opposite result.

In connection with these discussions of the direction of movement as symptom of cerebellar tumor, it is probable that the lesions more often act as destructive than as irritative factors.

Physiologists, as the results of their experiments upon animals, have frequently observed spasticity or rigidity. In some cases curvatures of the body, apparently the result of spastic conditions, have taken place. In some clinical re-

⁹ Bruce, Alexander, *Scottish Medical and Surgical Journal*, September, 1899.

¹⁰ Preston, *Alienist and Neurologist*, St. Louis, April, 1892.

ports spasticity and contractures are set down as among a comparatively common phenomena of cerebellar tumor.

Retraction of the head and neck, opisthotonos, and general tetanic rigidity have been recorded. In the experience of the writer tonic spasms and contractures are very rare in tumors strictly limited to the cerebellum. I have, however, seen these symptoms associated with hydrocephalus and in cases in which the tumor has invaded parts outside of the cerebellum, as for instance, the oblongata or pons. When present, the tonic spasticity may be on the side of the lesion or on the opposite side. The spasticity may be a transient symptom. It has never proved of diagnostic importance in my studies of cerebellar disease.

One reason for the difference between the reported results of lesions of the cerebellum experimentally produced and the effects of tumors resides in the fact that the former immediately and for a long time are irritative phenomena, while the latter, owing to their usually slow growth, produce their effect by inhibition, pressure, and destruction.

The asthenia, atonia, and astasia which Luciani so strongly emphasizes as the chief effects of destructive lesions of the cerebellum experimentally produced are well illustrated by clinical facts. The case of cerebellar tumor is asthenic, although not paralyzed, is atonic or flaccid rather than spastic, and is astatic or incoordinate. The extent and position of his asthenia, atonia, and astasia depend upon the extent and location of the lesion.

While clonic spasm is an infrequent local symptom of cerebellar tumor, it is occasionally observed. In a case recorded by Spiller, which was seen by the writer in consultation, the patient had at times fine twitching movements of the right extremities, although at times the movements were on both sides of the body.

Tremor, especially of the head and upper extremities, has been recorded as one of the results of physiological experiment on the cerebellum. It occurs in a large percentage of the cases of cerebellar tumor, and was a notable symptom in one or two of the cases seen jointly by Dr. Frazier and the writer.

My experience indicates that the muscular sense is not lost in cases of cerebellar disease. The patient may be ataxic as well as asthenic and atonic, and yet on testing him carefully for the muscular sense or its components, the so called senses of pressure, weight, posture, location, etc., these are not affected. Grainger Stewart and Gibson carefully tested the muscular sense and

found it unaffected in their five cases. Others have recorded the loss of muscular sense in cerebellar lesions, but as a rule without any details, and it is a question in these cases whether the loss of muscular sense has not been confounded with other manifestations, such as ataxia. Stereognostic perception is also unaffected in tumors and other lesions of the cerebellum.

In a series of cases appended to the papers of Dr. Frazier and the writer, the muscular sense, stereognostic perception, and all forms of cutaneous sensibility were studied, but with negative results, except in one instance in which a doubtful cutaneous hypæsthesia was present. When impaired sensation in the distribution of the fifth nerve is present in cerebellar disease it is probably an indirect or pressure symptom. I am not speaking now of cases of tumor of the cerebello-pontile angle, in which the fifth nerve or its roots may be directly implicated. The cerebellum is above all a motor organ; its most distinctive focal symptoms, vertigo, ataxia, asthenia, and nystagmus being affections of motility.

A few words might be said in this connection about the diagnosis of cerebellar neoplasms from tumors of one or two other regions of the brain.

Tumors situated in one lateral lobe, but invading deeply so as to involve the cerebellovestibular apparatus and perhaps the vermis, may need to be differentiated from tumors of the superior parietal region. The chief diagnostic points in favor of the tumor being cerebellar are the absence of astereognosis and that of symptoms showing the loss or disturbance of muscular or cutaneous sensibility. Nystagmus as a rule is not present in parietal tumors, although this is a rule not without exception, especially if the tumor should extend far enough backward to involve the visual motor region of the cerebral cortex. Vertigo may be present in a parietal tumor, but the peculiar and extreme form of vertigo which has been described as due to disturbance of the cerebellovestibular tracts and centres is not observed in parietal cases. These cases are generally more distinctly unilateral in their symptoms, although unilaterality is occasionally quite marked in cerebellar tumors. The invasion symptoms of parietal tumor will help in diagnosis.

Tumors of the cerebellum need occasionally to be differentiated from prefrontal growths. This diagnosis is difficult only when the tumor is confined to the external portion of one lateral lobe, so that the symptoms given, such as ataxia and nystagmus, are not marked or are not present at all. I have seen but little of the frontal ataxia of Bruns; so little indeed as to make me doubt-

ful of its existence as a true ataxia. The symptom when present is probably a pseudoataxia due to the impaired mentality of the patient in consequence of which his powers of attention and inhibition are so affected that he does not govern his movements quite normally. When a prefrontal growth is situated on the left, mental symptoms of a distinctive character are present, these being absent in cerebellar growths. The cerebellar patient is often feeble in pursuing his mental processes, which, however, are in themselves quite clear. If the prefrontal tumor invades backward, aphasia, agraphia, and unilateral motor paralysis may ensue.

As indicated when discussing the subject of nystagmus, disorders of ocular movements, and especially of associated movements, are among the most frequent symptoms of cerebellar disease. Various cranial nerve symptoms are often observed in tumor of the cerebellum, but these are not necessarily present. They are the result either of pressure in the case of tumors of large size and marked density or of the invasion of the oblongata and pons and the nerve roots by tumors situated toward the inferior surface of the cerebellum. I am not speaking here of the special forms of tumor of the cerebellopontile angle, as, for instance, those which arise from the eighth nerve, but of growths which originate in the cerebellum proper. Neural symptoms when present are of much importance in questions of focal diagnosis and of prognosis; in the former in deciding the side on which the lesion is situated, in the latter by pointing to a less favorable outcome than when the neoplasm is confined to the substance of the cerebellum.

The nerve symptoms may be referable to any of the cranial nerves or their connections from the third to the twelfth. Among the most frequent are those indicating paralysis or paresis of associated ocular movements, paresis of the musculature supplied by the sixth or the seventh nerve, impairment of hearing from implication of the cochlear portion of the eighth nerve, disorders of taste due to involvement of the glossopharyngeal or chorda tympani, and loss or perversion of sensation because of trigeminal disturbance. The nerves, their roots, or the tracts with which they are connected in the oblongatopons may be involved separately or conjointly. When the neural symptoms are due to pressure they are probably usually to be referred to direct nerve or nerve root involvement. While unilateral symptoms may point to true nerve implication, this distinction is by no means a sufficient one, as tumors of the cerebellum not infrequently

involve jointly one lobe, one peduncle, and one side of the oblongata or pons.

Among the pontooblongatal pressure symptoms which may result from a cerebellar tumor are hemiparesis and vasomotor, cardiac, and respiratory disturbances. Convulsions, unilateral or general, but more commonly the latter, with unconsciousness, have occurred in a considerable percentage of the cases which have come under my observation.

With our present knowledge and views regarding the anatomy and physiology of the cerebral olfactory apparatus, it is at times difficult to determine how loss of smell, which is common in cerebellar tumors, is produced. In some cases it may originate in much the same way as optic neuritis and blindness occur, that is, from neural inflammation or from nerve choking.

With regard to the deep reflexes, little that is of value in focal cerebellar diagnosis is as yet at our command. We have observed the knee jerks lost, exaggerated, crossed, and differing on the two sided either as regards loss, impairment, or increase. Unilateral differences are sometimes of corroborative value when the question of the side on which a tumor is situated is under consideration. In one of the cases appended, for instance, the knee jerk was exaggerated on the side opposite to that on which the tumor was presumably situated, probably because the neoplasm exerted pressure downward on the pyramidal tract before its decussation. The Babinski response is usually absent, although it was present on the side opposite the lesion in one case. The superficial reflexes are usually unchanged.

Incontinence of urine and feces is present in a few cases apparently as symptoms referable to the presence of the tumor. Such incontinence is of course present in cases of tumor of the brain, no matter what its situation, when the disease has advanced to such a point, or the suffering of the patient has become so great that his mind is obtunded.

Other symptoms which have been occasionally recorded in cases of tumor of the cerebellum are polyuria, glycosuria, and muscular wasting.

In the discussion of the papers of Bruce reference is made to the fact that tumors of one lateral lobe of the cerebellum may in some instances not give rise to symptoms, and, as indicated by Bruce, this is in those cases of lateral lobe disease in which the lesion does not extend inward far enough to invade the cerebellovestibular or cerebellospinal apparatus. This is not, however, the only explanation of cerebellar lesions without

cerebellar symptoms. In other cases of very slowly developing tumors the cerebellum gradually accommodates itself to the lesion. It is well known that cases both of cerebral and cerebellar tumors are recorded in which the growths have undoubtedly been present for many years, and the fact was not discovered until they were unexpectedly revealed by necropsy.

Bruce, as already indicated, has also called attention to the fact that a tumor symmetrically disposed as regards the vermis, that is so developing as to uniformly implicate both halves of the vermis and equally the adjacent portions of the lateral lobe may not cause marked disturbance of equilibrium. Those cases of tumors of parts adjacent to the cerebellum, like the quadrigeminum, for example, in which symptoms are not present, although necropsy seemed to show that the cerebellum was markedly compressed, can only be explained on the theory of compressed brain substance accommodating itself functionally to the gradually developing conditions. The same thing is observed in a notable degree in some cases of internal hydrocephalus in which, although the brain is almost reduced to a shell, the cerebral centres and tracts continue to functionate.

With regard to cases such as have been recorded by Spiller and others, and which are referred to by Weisenburg, in which a large portion or almost the entire cerebellum has been absent or sclerotic, some evidences of the lack of cerebellar influence will usually be found on close investigation.

In a series of eight cases, Nonne has reported three cases which presented the symptoms of tumor of the cerebellum. The symptoms of brain tumor disappeared either under mercurial treatment or spontaneously. Nonne believed that in none of them was syphilis present. Partial nerve atrophy was left in some of the cases. Nonne,¹¹ in his discussion of the cases, excluded such diagnoses as encephalitis, meningitis, abscess, thrombosis, multiple sclerosis, chlorosis, nephritis, intoxications, and infections, also syphiloma and tubercle. He also believed that they were not cases of hydrocephalus, although he was somewhat doubtful on this point.

In two cases of tumor not situated in the cerebellum, but so located as to obstruct the ventricular outlets, hydrocephalus was produced and the symptoms of cerebellar tumor were present. In three other cases in which no signs of internal hydrocephalus were present, cerebellar symptoms were exhibited. The necropsy in these cases showed absolutely nothing.

Cases such as these must be borne in mind when considering the diagnosis of a tumor of the cerebellum.

TUMORS OF THE CEREBELLOPONTILE ANGLE.

With regard to the connections of the growths with the nervous system, at least two forms of tumors are found in the cerebellopontile angle or recess, and this fact should be recognized when surgical procedure is contemplated. In the first place, the tumor mass may involve the substance of the cerebellum or one of its peduncles, and the oblongatopons, and, secondly, the tumor may originate in one or two of the cranial nerves and be largely confined to them, the acoustic being especially the seat of such growths. With regard to tumors in both the substance of the cerebellum and of the bulb, many have been put on record and several have been seen by the writer. In a case of multiple sarcomatosis for several weeks under my care, and later passing into the hands of Dr. Spiller,¹² who records the case in full in a paper on multiple sarcomatosis, tumors, probably sarcomatous, involved the nervous substance in both cerebellar recesses, numerous other tumors being present in other regions both of the brain and spinal cord. When a tumor involves somewhat deeply the substance of the cerebellum and pons, it can only be partially removed, and even to accomplish this it will be necessary to assume considerable risk, as the operation is both difficult and dangerous. The cerebellopontile tumors most amenable to operation are the fibromata of the eighth nerve, which will next be briefly considered.

Besides reviewing the literature of the subject, Fraenkel and Hunt have recorded five cases of tumors of this kind with necropsies. With regard to the particular nerves on which these tumors occur, they say that "the eighth shows a marked predisposition and is most frequently involved, rather rarely on both sides. The trigeminus is next in order. The facial is believed by some to be occasionally the seat of these tumors; its proximity to the acoustic nerve renders pathological decision difficult." One point of great importance with regard to these tumors of the acoustic nerve is their peculiar formation, the manner in which they are encapsulated and the ease with which they can be removed with operation if they are or become accessible through the work of the surgeon. They are usually oval or rounded and vary in size, some being as large as a hen's egg. They are attached to the nerve trunk, which has undergone atrophy because of their presence.

¹¹ Nonne, *Deutsche Zeitschrift für Nervenheilkunde*, Vol. lvi, 1904.

¹² Spiller and Hendrickson, *Am. Jour. of the Med. Sci.*, July, 1903.

The pathology of fibromata of the acoustic and other cranial nerves is fully considered by Weisenburg.

Although an acoustic neurofibroma is so closely related to the brain stem as to be within a few millimetres of it, nevertheless the symptoms of bulbar involvement may be entirely absent. This has been pointed out by von Monakow, in whose case vomiting, difficulty in deglutition, and bulbar disorders of circulation and respiration were entirely absent. Von Monakow¹⁸ indicates as the best diagnostic points for a neurofibroma of the acoustic, the absence of such symptoms as vomiting, dysphagia, etc., on the one hand, and on the other hand, the presence of general symptoms of cerebral tumor, such as headache, vertigo, and choked discs in association with cerebellar ataxia, rapidly developing deafness, paresis of the seventh and fifth nerves on the same side as the deafness, with associated ocular palsy, also on the same side, dysarthria and Gerhardt's symptom being absent. In such cases in addition, peripheral ear disease should be excluded. If ataxia is present, the tendency will usually be to deviate or fall toward the side of the lesion.

In the five cases of cerebellopontile nerve tumors reported by Fraenkel and Hunt, operation was attempted in only one; it would probably have been successful in one or two others if the procedure had been undertaken at the right time. In the case on which operation was performed the growth was nodular, was in the left ponto-oblongatal cerebellar space, and was of about the size of a hen's egg. It was broken up by the index finger and the fragments removed. The patient died of symptoms pointing to central cardiac and respiratory disorders.

Two cases of fibromata of the acoustic, of which photographic illustrations are given in the paper of Dr. Weisenburg, have recently fallen under my observation. In one case an operation was performed over the cortical facial region and a lesion was found in this position. The main lesion, however, was undoubtedly the tumor of the cerebellopontile recess. The chief focal symptoms were one sided deafness, tinnitus, facial monospasm, hypæsthesia on one side of the face, nystagmoid movements, slight paresis of right abducens, vasomotor and cardiac disturbances; severe headache, nausea, vomiting, and optic neuritis were also present.

The fuller history of this case is given in the paper of Dr. Weisenburg. The notes of the other case are appended.

In this case a fibromatous tumor of the acoustic was unexpectedly found at necropsy in the

cerebellooblongatopontile space. The record of this case is given to show how such a growth can be entirely overlooked. The necropsy revealed not only the presence of this tumor, but also marked hydrocephalus, which may have accounted for most of the symptoms presented by the patient, such as spasticity, mental hebetude, headache, and optic neuritis, but it was insufficient to account for them all. The patient's hearing on each side was never positively determined. Examinations for any of the special senses were unusually difficult after she came to the hospital, and grew more and more so as days advanced. It is probable that she had loss of hearing on the side of the growth.

The patient was a woman forty-eight years old. The facts which could be obtained regarding her history before admission to the University Hospital were meagre. It was learned, however, that three or four years before she had an attack which was supposed to be one of grippe, and following this, inflammation of the middle ear on both sides accompanied by pus, which required the membrane of the tympanum on the right to be opened. This history clouded the diagnosis as regarded involvement of the acoustic nerve by intracranial neoplasm; in addition, as already stated, it was difficult to make a careful examination, owing to her mental state.

It was also learned from one of her physicians that two or three years before coming into the hospital she had complained of a feeling of cushions under her feet, and that at this time she had some anesthesia of the right side of the face and of the right hand and leg. About a year before admission her legs began to grow stiff and she had sharp shooting pains in them. This stiffness increased and she had some difficulty of gait. At times she had been troubled with double vision. She had always been a sufferer from headache, but it was stated that this had not increased. For a year she had had difficulty in controlling her bowels and bladder.

Examination showed the patient to be dull and apathetic. Her memory was greatly impaired, she was easily confused, and it was at times almost impossible to fix her attention. Her legs were markedly spastic, being flexed at nearly a right angle. The Babinski reflex was not present. The knee jerks were exaggerated. The left pupil was considerably larger than the right. Sensation was apparently everywhere preserved, although it was difficult to test for fine differences in sensation. Facial and masseter paralysis were not present, and except as above noted, the examinations, which were thoroughly made, were negative. An eye examination by Dr. de Schweinitz showed double choked discs and many hemorrhages; there was no apparent muscle palsy.

An operation was performed by Dr. Frazier in this case for the relief of her general symptoms, the prefrontal region being selected. The ventricle was reached a short distance from the surface after the trephine opening had been made.

¹⁸ *Berl. klin. Wochenschr.*, August 13, 1900, No. 33, p. 721.

Probably a diagnosis could have been made in this case if the patient had been studied early and continuously. Late in the case the general symptoms were those of brain tumor, but the only focal symptoms which could be clearly determined by a study of the case and its history were the anæsthesia of one side of the face, and the probable impairment of hearing. Some of the symptoms, like the double spasticity, paræsthesia of the feet, and sharp shooting pains, seemed to point to spinal disease.

(To be concluded.)

Chronic Colitis and Its Treatment Based Upon Surgical Experience.—Von Beck, in *Fortschritte der Medizin*, for October 1, 1904, thinks the treatment of chronic colitis should be based mainly upon its ætiology. The physician should not be satisfied with such a diagnosis as chronic catarrh of the large intestine of nervous origin, for the nervousness is usually the result of the colitis. In 500 cases which came under his observation he found chronic inflammation in the region of the large intestine in 394 of them. The cure of the colitis depended in greater or less degree upon the removal of this inflammation. The most common varieties of this inflammation were perityphlitis, disease of the stomach and gall bladder, and disease of the female genital organs. Other causes which were discovered in certain cases were carcinoma, tuberculosis, and actinomycosis. In five of the cases in which there were persistently recurring attacks of colon disease, notwithstanding vigorous dietetic and other methods of treatment, the entire colon was excluded by anastomosis of the sigmoid flexure with the ileum. This procedure produced satisfactory results. On the basis of this experience the author offers the following propositions with reference to the treatment of chronic colitis:

1. The cause of colitis must be determined in every case and the treatment must be based upon the ætiology.

2. If the colitis is due to inflammatory processes in the vicinity of the colon, their fundamental foci must be controlled or removed, and operative procedures must be employed if possible.

3. If the causes are to be found in carcinoma, tuberculosis, or actinomycosis of the colon, the colon disease must be attacked by radical or palliative operative measures, including resection, enteroanastomosis, or colostomy.

4. If the colitis is due to a cause of some other character, dietetic or other symptomatic treatment may be attempted.

5. If the colitis is obstinate and yields to none of the methods which have been mentioned, it may be necessary to exclude the entire colon by anastomosis of the sigmoid with the ileum.

The author believes, as the result of his observation, that the large intestine in man is of minor importance, is a relic from the herbivora, and is so susceptible to chronic inflammations and malignant tumors that its exclusion can be well tolerated and can lead to no bad results.

THE CEREBELLAR SEIZURE (CEREBELLAR FITS) A SYNDROME CHARACTERISTIC OF CEREBELLAR TUMORS.

By CHARLES L. DANA, M. D.,

NEW YORK.

Among the most important contributions of recent periods to the symptomatology of cerebellar, or, at least, of posterior fossa tumors, are those of Dr. Fraenkel and Dr. Hunt, on the fibromata of the cerebellopontine angle. While the fact that tumors are frequently situated at this spot has long been known, and their symptomatology has been, to some extent, described, the fact that the existence of tumors in this position can often be recognized in the very early stage, that they are usually benign fibromata, at least at the beginning, and that they are often pedunculated, and could be very easily removed, if they could be safely reached, has been brought out very clearly and convincingly. The symptomatology of these "acoustic fibromata" thus forms a distinctly new chapter in the description of tumors of the posterior fossa. Knowing now their insidious beginning and slow onset, the watchful physician should learn to recognize them very early, and it is to be hoped that the time will come when the surgeon can always successfully remove them, as has already twice been done.

Since the original papers of Fraenkel and Hunt, the last of which appeared not many months ago, a case was recognized and observed by Dr. Waterman, the house physician in my wards, at Bellevue, and another case has been observed by Dr. Hunt, and verified by autopsy, while a third case is now being operated upon in successive stages by Dr. Woolsey. The article of Dr. Fraenkel, which accompanies this, is devoted in part to a further exposition of the symptoms of this group of what may still be called "cerebellar" tumors, since they, at least, produce largely cerebellar symptoms. It has been found, since the publication of the articles of these two physicians, that the problem is not always perhaps such a simple one as had been hoped, because, at times, in addition to the presence of a pedunculated fibroma in the cerebellopontine angle, there may be another tumor in the substance of the cerebellum. Furthermore, the tumors of this space, though usually fibromatous, may sometimes be tuberculous or sarcomatous or even bony, and there may be a picture of a cerebellopontine angle tumor, having the accompaniments of rapidity of progress, and other symptoms, which indicate that it does not belong strictly to the fibrous and pedunculated type.

Some years ago I had under observation a case in which I made the diagnosis of tumor of the

cerebellopontine angle, but in which the course of the symptoms was such as to lead me to think that it hardly belonged to the pathological group, that the authors referred to have described. The development of the symptoms, and the course of the disease, were so characteristic that no doubt of the existence of the tumor and its location could exist. My apology for presenting the story now is that it adds something to the symptomatology of tumors in that region and especially illustrates the phenomena of cerebellar seizures, which I shall refer to later, which I believe form a distinguishing syndrome of cerebellar disease, and more particularly perhaps of those tumors lying mainly outside the cerebellar.

The patient was a lady, aged 29 years, unmarried. Her mother was a healthy woman and her father a large, strong man, but he had become an alcoholic in later years. The brother and sister were well. The patient herself was born at full term (a fact which I mention because in one case of cerebellar tumor the patient was a seven months' child, and I was asked to state if that were a causative factor). The girl was of a nervous temperament, but grew up in fairly good health, and had no particular infections, aside from the ordinary ones of childhood. At the age of 15 years she had a polypus removed from her throat. At the age of 27 years she began to suffer from headaches and vomiting, and at the same time, or a little later, she suffered somewhat from deafness in the right ear. About six months later, the headache having continued, she developed some diplopia, and a year from the beginning of her trouble she lost the sight of the right eye. The deafness, meanwhile, was steadily increasing in the right ear. At this time she was seen by a neurologist, who made a diagnosis of cerebellar tumor. About a year after the onset of the symptoms she began to lose the sight in the left eye, and at this time she began also to have some ataxia in her gait. Thus, there was a gradual development of symptoms, first, of headache, occasional vomiting, deafness, ocular motor symptoms, optic neuritis, first in the right, then in the left eye, and awkwardness of gait. She had all along had occasional very annoying attacks of tinnitus and vertigo, but at the end of the first year these attacks began to be more frequent and severe, and they were, in fact, the most characteristic and distressing symptoms of her malady from that time on. She would have suddenly "rushes of blood to the head," during which she would feel a terrific roaring and crackling in the head and great dizziness, so that she could not stand, and would sink suddenly to the ground with at times loss of consciousness, but without nausea. The face was flushed and the pulse rapid. The attacks would last from five to thirty minutes. During this second and last year of her illness these seizures would come on every week or two, sometimes oftener; rarely she went three or four weeks without any. Usually they occurred in the day time when she was awake, but once or twice they came on while she was sleeping at night. As the disease

progressed they became more severe until, toward the end, they were always accompanied by loss of consciousness, and a stiffening and irregular tonic spasm of the limbs, but without any actual convulsions or forced movements. She would, in other words, suddenly fall down, and lie unconscious in a sprawling attitude, such as one would expect in a person with an injured cerebellum. There was no impairment of the intelligence at any time in the course of the trouble. I saw her only during the last three months of her illness. She then had an unsteadiness and awkwardness of gait, increased somewhat by her complete blindness. There was no paralysis, though the right arm was slightly weaker than the left, and there was no ataxia in the arms. The knee jerks were even and a little exaggerated. There was no anæsthesia or paræsthesia of the extremities. The optic atrophy in both eyes was complete. Deafness had extended from the right to the left ear, but the hearing was not entirely lost in the left ear. The sense of smell was lost, but that might have been due to some previous condition. The sense of taste was present. The ocular movements were irregular and ataxic, but there were no distinct paralyses of the ocular muscles. Toward the last there developed a paresis of the right side of the face, and a slight anæsthesia of the fifth nerve, with neuralgic pains on the same side. The patient finally died of exhaustion. The cerebellar symptoms, and the progressive involution of the eighth, seventh and fifth nerves, showed conclusively, it seems to me, the seat of the lesion.

The particularly interesting clinical symptom is that connected with the seizures which this patient had. At the beginning they were not much different from the ordinary vertigo and tinnitus, which come on with cerebral and cerebellar tumors. But their later development, into what may be termed strictly cerebellar or cerebellopontile seizures, seems to be an instructive feature of the case. They were, I presume, due originally to irritation of the labyrinth, and later to pressure upon and irritation of the pons and cerebellum. The patient had no forced movements, or any particular tendency to walk to one side more than the other.

The vertiges and seizures of cerebellar tumors have seemed to me a subject of special interest, and one about which not much has been written. Reviewing my own experience and that of other writers, I find that this cerebellar syndrome is not infrequent. A patient under observation now with cerebellar tumor experiences suddenly a sense of pain beginning at the occiput, and running over the brow, followed at once by tinnitus, vertigo, apparent loss of consciousness, and instant sinking to the ground, not so much due to loss of consciousness as, apparently, to a sudden absence of cerebellar innervation, and a total loss of power of equilibrium.

A patient with acoustic fibroma, also now under observation, has a sudden increase in tinnitus, vertigo, and blackness before the eyes, and he has to seize something or he would fall. In a few severer seizures he entirely lost consciousness, fell to the ground, and remained for several minutes in a tonic spasm. In cases of cerebellar tumor one characteristic of the vertigo is that it is brought out on sudden change in the position of the body. This

was not seen in the extracerebellar cases. In pons tumors there is sometimes a sudden short coma, and we may attribute the short seizures with loss of consciousness to involvement of the pons and pressure upon its vessels. General convulsions do at times occur in cerebellar tumors when these are large and rapid in growth, but they are not characteristic or frequent in cerebellar disease. Changes in pulse rate and respiration sometimes accompany the cerebellar seizures, but they also are not frequent or characteristic.

But the special syndrome of cerebellar and posterior fossa tumors causing irritation and pressure is seizures characterized by:

1. Loud, high pitched tinnitus or roaring and crackling noises, suddenly increased in intensity.
2. Vertigo usually objective and with or without forced movements.
3. A tendency to drop or fall in one direction or another instantly to the ground.
4. Sometimes sudden blindness and loss of consciousness.
5. In severe attacks, tonic spasms generally of an extensor type. This lasts from one or two to five or ten minutes.

A closer study of the subjective states of individuals with cerebellar tumors will, I believe, show more strikingly than is supposed the uniformity of the tinnitus seizure, the severity of the vertigo, and the tendency to lose consciousness or vision for a moment. The sudden dropping down or falling to one side is a feature also that I believe will be found not uncommon. These seizures, I may add, are probably more common and typical in the older patients than in young children.

It may be said that this syndrome is essentially only a labyrinthine vertigo, but I believe it to be more than that. The sudden falling, a forced movement, the loss of consciousness, the tonic spasm are very rare in simple labyrinthine disease. In this latter condition there is often also a tremendous subjective vertigo, nausea, and a compelling desire to lie down and keep very still. The cerebellar "fits," I may add, I have seen rather typically in a case of hereditary cerebellar defect.

53 WEST FIFTY-THIRD STREET.

Clinton County, N. Y., Medical Society.—The following officers have been elected for the ensuing year: President, Dr. G. D. Dare; vice-president, Dr. J. H. LaRocque; secretary, Dr. D. S. Kellogg; treasurer, Dr. Frank Madden; delegate to State medical society, Dr. J. H. LaRocque. After the close of the meeting the Plattsburgh Physicians' Club was organized, with the following officers: President, Dr. Frank Madden; secretary, Dr. T. A. Rogers; committee on entertainment and programme, Dr. Silver and Dr. Rogers; committee to draft by-laws, Dr. Madden, Dr. Fairbanks, Dr. Ransom, and Dr. Woodruff. The first meeting of the club is to be held January 24th, at the home of Dr. Frank Madden.

REMARKS UPON THE SURGICAL ASPECTS OF TUMORS OF THE CEREBELLUM.

By CHARLES H. FRAZIER, M. D.,

PHILADELPHIA,

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF PENNSYLVANIA; SURGEON TO THE UNIVERSITY HOSPITAL.

ANATOMICAL CONSIDERATIONS.

The difficulties that attend any attempt on the part of the surgeon to expose, much less remove tumors from the cerebellum, differ very materially from those encountered in tumors of the cerebrum. Speaking upon this subject on another occasion I said that it seemed as though, in encompassing the cerebellum with such large cranial sinuses, nature has intimated that this organ was never to be subjected to exposure at the hands of the surgeon. When one takes into consideration the position of the lateral and the occipital sinuses with relation to the only means of access to the cerebellum, and the plane of the tentorium cerebelli, one realizes at once that there are especial technical difficulties in surgical attacks upon the cerebellum. (See Fig. 1.) Furthermore, it must be remembered that there are very distinct dangers attending manipulations upon the cerebellum and more particularly, if, in an attempt to get sufficient exposure to excise a tumor, one should make too much traction upon the medulla oblongata. Even when one has removed a considerable portion of the skull below the superior curved line, there will be exposed to view but a small portion of the gross surface area of the cerebellum. Neither the upper surface, that is in relation with the tentorium cerebelli nor the anterior surface which is in relation with the petrous surface of the temporal bone, nor the mesial surface will be exposed to view by this procedure; whereas in the cerebrum the entire cortex and a considerable portion of the base can be laid bare by a very simple osteoplastic operation. Furthermore the cavity of the cerebellum is very much smaller than that of the cerebrum, so that there is very much less space in which to conduct the manipulations necessary either for exposure or removal of the tumor. In the adult skull one hemisphere of the cerebellum is contained in a cavity whose greatest dimension is only 10.5 cm. In addition to the difficulties that are associated with operations in a space so small and difficult of approach one is hampered further by the fact that even under normal conditions the cerebellar hemispheres are compressed in a relatively smaller space than the hemispheres of the cerebrum, and are under such tension that when tension is relieved by the reflection of a dural flap the cerebellar tissue almost invariably protrudes through the opening. The tissues cannot be displaced or retracted neither to the same degree nor with as much ease as can

the cerebral lobes. Thus the operator will be embarrassed in attempting to expose a lesion deeply situated, as for example at the cerebellopontile angle, a favorite seat for tumors.

In addition to the larger sinuses, the lateral and occipital, certain tributaries of sufficient size to cause, when injured, profuse and sometimes alarming hæmorrhage, penetrate that portion of the occipital bone which must be removed. The most constant of these is a branch of the lateral sinus which passes obliquely through the skull and appears in the surface between one and two centimetres to the inner side of the mastoid process; occasionally one or more will be found just below the superior curved line in the neighborhood of the occipital protuberance.

The occipital bone overlying the cerebellum is very variable in thickness. In the region of the mastoid process and of the occipital protuberance the bone is exceedingly thick, but from these two processes the thickness of the bone gradually decreases until at a point about midway between the two it will be found comparatively thin.

INDICATIONS FOR OPERATION.

In general terms it may be said that the indications for operation in cases of suspected tumors of the cerebellum do not differ materially from those which have been endorsed in the treatment of tumors of the cerebrum. In both classes of cases once the diagnosis has been made, operation if it is to be performed at all, should not be postponed for any length of time. Physicians are too prone to put off the time indefinitely almost and to spend months in the often fruitless administration of antisyphilitics, or to spend an unwarrantable amount of time in efforts to establish a diagnosis beyond a peradventure of doubt, or to localize the tumor with mathematical accuracy. Kocher says there should be less delay in bringing to the surgeon a lesion of the encephalon, whether it be a neoplasm, tubercle, gumma or abscess. "There is no more excuse to-day for delaying operation in cases of tumors because the tumor could not be exactly localized, than there would be for declining to operate upon a case of intracranial hæmorrhage because one was unable to determine positively the seat of the clot. Failing in one place to find the tumor, other trephine openings may be made or a very extensive area may be exposed by an osteoplastic resection. How often, Kocher says, has one trephined over the anterior branch of the middle meningeal artery when the autopsy revealed the clot in the region of the posterior branch." The surgeon might come in for his share of criticism because of his lack of precise knowledge concerning the neurological aspects of the disease. In order that the very best

results be obtained the internist and the surgeon must work hand in hand in this as well as other fields. In cases of suspected tumors of the viscera an exploratory operation is now regarded as perfectly justifiable, and why? Because physicians have come to realize that if operation is postponed until the presence of the tumor can be demonstrated by palpation or other means, the lesion is by this time so extensive that the time for a radical operation has passed. As the exploratory operation is recognized as the surest, safest, and most reliable diagnostic measure in tumors of the stomach, it should be considered of equal value and importance in tumors of the brain. Postponement of operation should be discountenanced if for no other reason than because in cases of long duration patients with tumors of the brain make very poor subjects for operative intervention; the operation is of itself one of considerable gravity and the condition of the patient should be so good as to enable him to withstand its depressing effect.

Unfortunately tumors of the cerebellum are in the majority of instances more difficult of localization than tumors of the cerebrum and in many cases localization is well nigh impossible. Instead of regarding this, as has been the case so often, as a reason for delay, the difficulty of localization should be considered rather as an indication for an early exploratory operation. Just so soon as the diagnosis is with a reasonable degree of certainty assured, just so soon should the operation be performed, providing other measures have failed and the operation per se is not contraindicated.

Operation as a Palliative Measure.—Under certain circumstances we despair of being able to perform a radical operation; either the tumor cannot be found or cannot be localized; it may be inaccessible, or it may have attained such proportions as to make its removal impracticable. In any of these contingencies a palliative operation is justifiable and in some cases should be regarded as imperative. The headache, vertigo, and vomiting, so constant in cerebellar tumors, make the life of the patient pitiable and yet he may be relieved of all of these symptoms for a considerable time by adopting such measures as will relieve pressure. But the strongest argument against delay of operation in the treatment of cerebellar tumors is the possibility of being able to save the patient's vision: choked disc is one of the most constant symptoms and if permitted to continue unrelieved too long, an optic neuritis will develop and the time for complete or even partial restoration of vision will have passed. Nothing could be more striking than the results of palliative operation in one of our patients (Case 4). The patient before the operation suf-

fered from intense headache, was almost blind, and vertigo was so pronounced that he could not stand without support. The tumor could not be found but a large portion, perhaps one third to one half of one cerebellar hemisphere, was removed. His headache was relieved at once, within a week he was able to see as he lay in bed small specks on the ceiling, and on getting up was able to go about with but very little instability. Nothing could be more gratifying to the physicians in attendance than the relief which was afforded the patient by this comparatively simple procedure. In one of Krause's cases, after a palliative operation, the patient was relieved of many of the subjective disturbances and lived for a period of three years in comparative comfort.

Operative Technique.—Regarding the position of the patient, it is advisable to operate with his head and shoulders considerably elevated. This will diminish the hæmorrhage to a certain extent. The effect of the elevated position upon the blood pressure may be counteracted by applying a firm bandage to the lower extremities. In order to afford greater freedom for the necessary steps of the operation, I use an extension—a very simple appliance—which is easily attached to the operating table and upon which the head rests (see Fig. 2). While using it in all operations upon the brain I find it most serviceable in operations upon the cerebellum where the quarters are especially cramped. In two operations upon the cerebellum Schede placed his patients in the sitting posture, leaning far forward. This posture, according to Schede, diminishes to a considerable degree the hæmorrhage, but the position is a very awkward and difficult one in which to retain the fully anæsthetized and relaxed patient. The patient may be placed upon his side but it is difficult to retain the patient in this position and there is always the tendency of the patient to roll over on his side, in which position the respiratory act will be embarrassed, and, inasmuch as many of the sudden deaths are due to respiratory failure, it is advisable to take such precautionary measures as will avoid any disturbance of the respiration.

Incision.—The incision should begin at the tip of the mastoid process on the affected side and follow a line parallel with, but one centimetre above the superior curved line, to the median line. From this juncture a vertical incision may be made downwards to enable one to reflect the flap sufficiently to expose the field of operation. Hæmorrhage from the scalp in this region is so profuse that some precautions should be taken to reduce to a minimum the amount of blood lost. A very excellent plan is to incise but an inch or an inch and a half at a time, proceeding at once to arrest the hæmorrhage in one

section before incising the next. Considerable bleeding may be prevented if one reflects the pericranium simultaneously with the overlying muscles and their attachments. If this precaution is taken the muscles will not be mutilated to the same extent as would be necessary if an attempt was made to reflect them independently of the overlying periosteum. What may be not only a troublesome, but an alarming feature is the hæmorrhage from the various sinuses that traverse the occipital bone; these have already been referred to in the section on the anatomy. Suffice it to say that one should always be prepared with suitable means for controlling the bleeding from this source, since if uncontrolled, the patient may lose in a very short time a pint of blood or more. In one of our cases (Case 5) two anomalous sinuses almost as large in diameter as a quill were found near the occipital protuberance. Before the hæmorrhage could be checked the patient lost so large a quantity of blood that it was deemed advisable to suspend further interference until the patient had recovered fully from the effects of this complication. Following the administration of appropriate remedies, the patient reacted within a reasonable time, but about twelve hours after the operation, suddenly and without any warning, the cardiac and respiratory functions failed and within ten minutes the patient was dead. Whether the loss of so much blood had anything to do with the termination of the case, is a matter purely of speculation. This instance is cited solely as an illustration of what may be a very serious complication, namely, hæmorrhage from the venous channels traversing the occipital bone. One should try to control the bleeding first with Horsley's wax and if, as in the case above referred to, this fails, the outlet of the sinuses should be closed with plugs of wood, which can be whittled to the proper thickness and length from ordinary swab sticks.

There need be no anxiety about the cranial sinuses as a possible source of hæmorrhage. The lateral sinus is fully exposed to view when the bone has been removed, and injury to this structure could result from carelessness only. The occipital sinus does not come within the field of operation unless one intends to remove the intervening bone, in which case the sinus will be exposed to view, and if necessary may be ligated (see Fig. 5).

Removal of Bone.—With Krause, Schede, and others I believe that it is unnecessary to preserve the overlying bone, therefore, the osteoplastic flap, which has done so much to revolutionize the surgery of tumors of the cerebrum, is not to be employed in the exploration of the cerebellum. As both V. Bergmann and Kocher have said, the muscles and

aponeurosis are thick enough at this point to offer adequate protection to the underlying structures and to make bony closure of the opening unnecessary.

An opening in the skull is made preferably with a chisel at a point about midway between the occipital protuberance and mastoid process. Here the bone is comparatively thin and as Foirier says this is the point of greatest safety. The opening so made is enlarged with rongeur forceps in all directions; outwards as far as one can go without opening the mastoid cells, upwards until the lateral sinus is entirely exposed to view, inwards to within a centimetre of the median line, and downwards to a point at least one centimetre distant from the foramen magnum. The removal of bone will be facilitated by using rongeur forceps, the blades of which are at an angle of about 65 degrees with the handles. As one approaches the region of the lateral and occipital sinus, the forceps should be laid aside for a moment and a dural separator introduced to separate the dura and the sinuses from the skull.

I prefer the chisel to the trephine for making the initial opening for two reasons: first because the opening can be made more rapidly with a chisel, and secondly because the operation of a trephine in this region is a somewhat awkward procedure.

Exploration.—After a dural flap, with its base downwards, has been reflected, one proceeds to search for the tumor, unless it has been decided to resort to the *two stage operation*. The principles which we have applied in deciding this question are precisely those which have been adopted in our operations for tumors of the cerebrum (see *American Journal of the Medical Sciences*, February, 1904). If, when the preliminary stages of the operation have been completed, the condition of the patient, as revealed by the blood pressure and pulse record, is one of depression or shock, the final stage of the operation should be postponed until the patient has reacted. Having decided to continue the operation the surgeon proceeds to inspect and palpate the surface exposed to view. If the cerebellar tissues protrude considerably through the opening once the dura is incised, the presence of a tumor or an internal hydrocephalus should be suspected. It should be borne in mind, however, that under normal conditions the cerebellum is under greater tension than the cerebrum, and when the dura is incised the normal cerebellum will protrude in many cases through the opening to a slight degree.

If the clinical symptoms, to which are added the presence of an anomalous condition revealed by the sense of sight or touch, lead one to believe the tumor is situated in the lateral hemisphere, the

subsequent steps of the operation should consist in an exploratory incision into the cerebellar tissue, and, if the tumor is found, in its complete extirpation. The impunity with which we can freely incise the cerebellar hemisphere without the risk of such disturbance of function as would follow a similar procedure in the motor area of the cerebral cortex should be borne in mind. A failure to find or expose a tumor of the cerebellar hemisphere because of an insufficient exploratory incision should be regarded as inexcusable unless the tumor was of very small dimensions. If on the other hand there is reason to believe the growth is situated at the cerebellopontile angle, a favorite site for cerebellar tumors, the subsequent steps of the operation will be attended with some difficulty. It may be possible in exceptional cases with the aid of a retractor to displace the cerebellar tissue sufficiently to expose the tumor, but in the great majority of cases one must resort to one of two methods to bring the tumor into view; either a portion of the cerebellar hemisphere must be removed or the ventricles must be punctured.

PUNCTURE OF THE VENTRICLES.

This procedure has been resorted to for two purposes, first as a purely palliative measure to relieve tension and again to relieve tension in order to render it possible to make a more thorough exploration of the cerebellar surfaces. Puncture of the ventricles is unfortunately an operation of unusual gravity and the danger attending it is so great in comparison to the possible benefit as to make it a procedure of questionable propriety. Many cases have been reported in which the results were disastrous. In one reported by Krause, a scalpel was introduced into the lateral ventricle, a drain introduced and about 200 c.c. of cerebrospinal fluid were withdrawn. The intracranial tension was relieved to such a degree that the operator was able to see the superior vermiciform process, but the patient collapsed immediately after the fluid was withdrawn. Heidenhain's experience was equally disastrous. Thinking he was dealing with an idiopathic hydrocephalus and that the relief of pressure would have a beneficial effect he tapped one lateral ventricle and the patient died suddenly on the night of the operation. Heidenhain attributed his death to the sudden disturbance of pressure. The operation has been practised by a number of surgeons, and in one instance with favorable results, but in the majority of cases the patient died immediately or soon afterwards.

LUMBAR PUNCTURE.

V. Bergmann attributes the relief which follows palliative operations for tumors of the brain more

to the escape of cerebrospinal fluid than to the removal of a large section of the skull. Therefore in those cases in which the pressure symptoms are very marked but the tumor cannot be localized he recommends the removal of the cerebrospinal fluid by Quincke's lumbar puncture. This procedure he says is much to be preferred to any others, but failing in this recourse should be had to direct puncture of the lateral ventricles. According to Oppenheim lumbar puncture is indicated in a very limited number of cases, chief among which are those in which the tumor is associated with an internal hydrocephalus and especially when the tumor encroaches upon the posterior fossa and threatens the life of the patient. In a series of 50 cases collected by Piolet (*Archives provinciales de chirurgie*, Vol. x, p. 728) lumbar puncture was employed in eight cases; in four patients there was transitory amelioration, and four died within a few days. The sudden disturbance of pressure is no doubt responsible for a large majority of the fatalities. In a few cases the fatal issue has been attributed to the pressure of the structure of the posterior fossa against the foramen magnum, an accident which could easily happen when the communication between the cerebral and spinal cavities was partly or altogether shut off and the vacuum created by aspiration drew the pons and medulla forcibly into the foramen magnum. If lumbar puncture is resorted to, such an apparatus should be used as Koenig suggested, in which the pressure is recorded while the fluid is being withdrawn. With this precautionary measure the danger of lumbar puncture would be reduced to a minimum. Fürbinger who is very much opposed to this practice attributes the deaths to pressure exerted upon the bulb by the arrest of cerebrospinal fluid from the ventricles at the foramen of Magendie.

CONTINUOUS OR INTERMEDIATE DISCHARGE OF CEREBROSPINAL FLUID.

The advisability of affording means for the escape of cerebrospinal fluid as a palliative measure might well be considered in connection with puncture of the lateral ventricle or lumbar puncture. There are cases on record in which, subsequent to operation, the flap has been punctured repeatedly for the purpose of relieving tension. After an exploratory operation, in which the tumor was not found, Terrier punctured the flap repeatedly and withdrew a considerable quantity of fluid, but the patient died in the third week after this form of treatment was adopted. Jaboulay noticed the beneficial effect attending the escape of cerebrospinal fluid through a fistula in the cicatrix and recommends the establishment of such a fistula in cases in which the improvement after operation was only

transitory or in which there was no improvement. Theoretically at least such a treatment should afford some relief from the effects of intracranial pressure and might be justifiable in inoperable cases, but one must bear in mind the constant danger of infection that must needs attend the presence of a communicative tract between the surface and the underlying structures.

EXPOSURE OF THE CEREBELLOPONTILE ANGLE.

To return to the question of exploration from which we digressed to consider the propriety of puncture of the lateral ventricles: To enable one to expose a tumor situated in the cerebellopontile angle two methods were proposed, tapping of the lateral ventricles, and removal of a large portion of the cerebellar hemisphere. The former method we disapprove of on the grounds that it is so fatal in its tendencies. The alternative on the other hand is attended with very different results. The impunity with which large sections of cerebellar tissue may be cut away not only without endangering life but without disturbance of function is an observation which was made by physiologists long ago. That the deduction naturally to be drawn from this bit of laboratory information has not been made use of by surgeons more generally is a matter of some surprise. The danger of exerting undue pressure or traction upon the pons or medulla in attempting to expose or remove the tumor is more to be dreaded than any other stage of the operation. It was only recently that Woolsey (*Annals of Surgery*, September, 1904) reported a case of neurofibroma of the acoustic nerve; the tumor was removed but the patient died three hours after the operation, and death was believed to be due to hæmorrhage within the pons. Woolsey was convinced that this was due to the traumatism indispensable to the frequent introduction and withdrawal of the fingers engaged in the removal of the tumor. Here is a case in which had a considerable portion of the hemisphere been removed prior to the attempts to extract the tumor it is more than likely that the unfortunate accident would not have occurred. My experience with this procedure has been limited to two cases which will be referred to again. In one of these (Case 2) a considerable portion—from one third to one half—of the hemisphere was removed deliberately in searching for the tumor, without any appreciable effect upon the patient's general condition. In another case (Case 4) the same practice was adopted with equally negative results in so far as the patient's respiratory or circulatory functions were concerned. In neither of these cases was the tumor found at the first operation, but the amelioration that followed was striking. At a second operation upon one of these (Case 2) the tumor presented

FIG. 1.—Vertical section of head, showing the comparatively small cavity in which the cerebellum is contained and its inaccessibility. Note the distance between the cerebellum and the cutaneous surface; note also the angle of the tentorium and the position of the lateral sinus.

FIG. 3.—Photograph of a horizontal section of the head cut on a level with the external auditory meatus; *a*, representing a point at the cerebellopontile angle; *b*, the auditory nerve entering the internal auditory meatus; *c*, *d*, *e*, three points on the skull. Note the distance between point *a* and the points *c*, *d*, and *e* as illustrating the shortest route to the cerebellopontile angle respectively. The shortest distance from the skull to the angle is measured along a line drawn between *a* and *c*. The farther away from *c* or the nearer to *e* the greater will be this distance.

FIG. 2.—“A head rest” that may be used to advantage in operations upon the head. The device is a very simple one and does not require a screw or bolt to secure it in place.

FIG. 4.—The larger figure to the left illustrates the operation for the combined exposure of one cerebellar hemisphere and the occipital lobe of the cerebrum. The smaller figure, above and to the right, illustrates the structures in relation to the anterior aspect of the cerebellum and the petrous portion of the temporal bone. Attention is called especially to the position of the 5th, 7th, and 8th cranial nerves. This drawing was made by viewing the structures from the lateral aspect, such an exposure as would be made in exploring for tumors of the cerebellopontile angle. 1. Osteoplastic flap reflected in an operation for the combined exposure of occipital lobe and cerebellum. 2. Ninth, tenth, and eleventh cranial nerves. 3. Auditory nerve drawn to one side by refractor in order to expose. 4. The facial nerve which lies directly beneath it. 5. The root of the trigeminus as it enters the groove at the apex of the petrous portion of the temporal bone.

FIG. 5.—Operation for the simultaneous exposure of both cerebellar hemispheres, necessitating ligation of the occipital sinus. 1. The occipital sinus, which has been ligated previously and reflected with the dura. 2. Mastoid process. 3. A large tributary of the lateral sinus, invariably opened in cerebellar craniectomies and of varying dimensions; said to be sometimes as large as the lateral sinus. 4. Lateral sinus. 5. Occipital protuberance. 6. Occipital sinus.

itself upon the surface of the remainder of the cerebellar tissue and was removed without any difficulty. This experience at once suggested to my mind what would seem to be additional argument in favor of the deliberate removal of a large portion of the hemisphere; on the one hand serving as a means of affording adequate exposure with the minimum degree of traumatism to pons and medulla, on the other serving as a means of relieving intracranial tension temporarily, and at the same time, by removing a certain amount of resistance, of facilitating the growth of the tumor toward the surface of a point where it can be more easily seen and removed. Last year Hudson (*American Journal of the Medical Sciences*, September, 1903) reported two operations for cerebellar tumors, in one of which at least a large portion of the hemisphere was removed in searching for the tumor. The patient reacted promptly and although the tumor was not found, began at once to improve. On a subsequent occasion the wound was reopened and a large cyst found and evacuated. I feel convinced that this procedure, if more universally adopted, will do much toward increasing the percentage not only of tumors found, but of tumors removed, and will at the same time reduce the mortality.

SHORTEST ROUTE TO THE CEREBELLOPONTILE ANGLE.

Before concluding our remarks upon the means of exposing tumors in the cerebellopontile angle a word should be said concerning the best method of approach. One has but to turn to a cross section of the cerebellum to see that the shortest distance from the surface of the skull to this snug corner is along a line parallel with the petrous portion of the temporal bone (see Fig. 3). Krause, in describing an operation for the division of the eighth nerve (*Beiträge zur klinische chirurgie*, Bd. XXXVII, Heft. 3), and others have made this anatomical observation. The distance along this line being the shortest it goes without saying that the cerebellopontile angle should be approached from the lateral rather than superior or inferior aspects of the cerebellum. The bony opening should extend as near to the mastoid process as possible. This is not only the shortest but the safest route in that the manipulations are carried on at a point farthest distant from such vital structures as the pons and medulla.

OPERATIONS UPON THE FIFTH AND EIGHTH NERVES IN THE CEREBELLAR FOSSA.

In an exploration of the anterior aspects of the cerebellum in the cerebellopontile angle for tumors, one exposes the posterior plane of the petrous portion of the temporal bone, and with it the fifth, seventh, and eighth nerves (see Fig. 4). The seventh and eighth nerves will be seen passing from

the cerebellum to enter the internal auditory meatus. The eighth nerve is the larger of the two and overlies the seventh nerve in such a way that it almost entirely conceals it from view. Farther along, at the apex of the petrous portion of the temporal bone, will be seen the sensory root of the trigeminal as it passes into the groove in which it traverses the petrous bone to enter the Gasserian ganglion. These three nerves, together with the ninth, tenth, and eleventh, may be said to be accessible, so that it is quite possible, if the indications arise, to divide any of them. It is not likely that, in operations for the relief of trifacial neuralgia, one would be called upon to divide the sensory root in the cerebellar fossa because the root and ganglion are more easily approached by the temporal route. In one of the cases of our series we seriously discussed the possibility of dividing the root in the cerebellar fossa and fully intended to do so under certain conditions. The case was one in which there were certain symptoms of cerebellar tumor and in addition intense trifacial neuralgia. If the tumor could not be found it was thought best to afford the patient relief at least from the neuralgia by dividing the sensory root. However, a cyst was found and evacuated and no further intervention seemed advisable. The patient was relieved entirely and has remained free from pain now more than a year since operation. There is no conceivable indication for any operative attack upon the seventh nerve within the fossa, but in the case of the eighth nerve Krause has recommended and practised its division for the relief of persistent tinnitus aurium. As recommended for tumors of the cerebellopontile angle, so here the nerve should be approached from the lateral rather than posterior aspect as from this point is measured the shortest distance from the skull to the nerve. The only difficulty, if there is any in the operation, will be met with in separating the eighth from the seventh nerve. The latter as has been said lies directly behind as one views the field from the side and the precaution must be taken to separate one from the other before attempting a nerve section. This is readily done with the aid of a small blunt hook (see Fig. 4).

SIMULTANEOUS EXPOSURE OF BOTH HEMISPHERES; BILATERAL CRANIECTOMY.

The difficulty in localizing cerebellar tumors is known to all clinicians. In an analysis of the 116 cases which we have collected we find that in 55 per cent. the operation was a failure because the tumor was not found. The diagnosis of cerebellar tumor is in many cases not so difficult, but in many of these it will be almost impossible to determine beforehand whether the tumor is in the right or left lobe.

Therefore in the course of an exploratory operation, when one has failed after a thorough search to find the tumor on the side which was opened first one must decide whether to proceed at once to explore the opposite side. In most instances further exploration should be postponed until the patient has reacted from the effects of the injury already inflicted. In one of our cases already referred to (Case 4) a section of the cerebellar hemisphere was removed to relieve tension temporarily and with most gratifying results. But whether this procedure is justifiable in the light of the probable existence of a tumor on the other side, might with propriety be questioned. In order to enable one to examine both hemispheres at one sitting the authors discussed the feasibility of performing a craniectomy on both sides and removing the intervening bone. This operation was performed upon the cadaver from which the illustration in Fig. 5 was drawn. The operation may be carried out as follows: An opening is made on either side in a manner similar to that when the operator is confined to one side. The dura and with it the superior longitudinal sinus are separated so that they may escape injury when the overlying bone is divided; a pair of forceps or preferably a Gigli saw may be used to section the intervening bridge of bone. The Gigli saw is to be preferred because it is less likely to comminute the bone, which must be divided very near the foramen magnum. The falx cerebelli is punctured in either side of the occipital sinus and the sinus divided between two ligatures (see Fig. 5). This will enable one to reflect a flap of the dura covering both hemispheres and afterwards to displace the cerebellum with greater freedom than would be possible if an unyielding bridge of bone remained between the two openings. In the preparation of this paper we found upon perusal of the literature that this procedure has been recommended by Kocher, Nothnagel (*Path. u. Ther.*, Vol. IX), and Krause (*Beiträge zur klin. Chir.*, Bd. XXXVII). The latter performed this operation in a case in which there was much uncertainty as to the position of the tumor; in order to relieve tension still further, he punctured one lateral ventricle. The results were reported to be satisfactory in so far as the freedom with which the various aspects of the cerebellum could be exposed. The patient died one week later and the autopsy revealed an internal hydrocephalus, but no tumor. We are not prepared to endorse this operation as a routine procedure but believe it should be restricted to those cases in which the tumor is believed to occupy a position near the mesial surface. Under any circumstances it should be practiced at two sittings; the additional trauma and hæmorrhage which must accompany such an extensive incision and the removal of such

an extensive section of bone would we believe add materially to the gravity of what under any circumstances is an extraordinarily serious operation.

LIGATURE OF THE LATERAL SINUS.

A discussion of the operative procedures in the region of the cerebellum would be incomplete did we not include some reference to ligation of the lateral sinus. In an attempt to expose tumors particularly of the anterior surface of the cerebellum the operator is hampered by the tentorium cerebelli, and the suggestion has been made by Kocher, Krause, and others that the tentorium cerebelli be divided down to the petrous portion of the temporal bone after the lateral sinus has been ligated. It is stated by Krause that one of the sinuses can be ligated without much risk, and in at least one occasion the idea was put into effect. The advantage to be gained by this modification of the technique I do not believe compensates for the additional risk that must be entailed. If the mortality following operations upon the cerebellum is to be reduced, the technique must be as simple as possible, the least degree of traumatism must be inflicted, the smallest possible insult offered to the tissues; therefore we should discard the more complicated procedures and those which interfere to a greater degree with the circulation and functional activity of the structures concerned.

SIMULTANEOUS EXPOSURE OF THE OCCIPITAL LOBE AND CEREBELLAR HEMISPHERE.

Included on the list of doubtful diagnoses are those in which there is a reasonable doubt as to whether the tumor is situated in the cerebellum or the occipital lobe. In such cases one could at one sitting explore first the cerebellum by a craniectomy and the occipital lobe by a craniotomy (see Fig. 4).

(To be concluded.)

Charitable Bequests to Philadelphia Institutions.—By the will of William S. Bunting \$500 was bequeathed to the Episcopal Hospital toward the establishment of a free bed. Five hundred dollars was also bequeathed to the Home for Incurables toward the endowment of a free bed in memory of the deceased's mother.

By the will of Henry Norris \$5,000 was bequeathed to the Pennsylvania Hospital, \$5,000 to the University Hospital, \$5,000 to the Children's Hospital, and \$5,000 to Haverford College. Mr. Norris died in December at his home, 1903 Walnut Street, aged 94 years.

By the will of Charlotte S. Bolt \$500 was bequeathed to St. Mark's Home for Aged and Infirm Women.

By the will of James Heckman, of Doylestown, Pa., \$1,000 was bequeathed to the Methodist Hospital of Philadelphia.

THE PATHOLOGY OF CEREBELLAR TUMORS.*

By T. H. WEISENBURG, M. D.,

PHILADELPHIA,

INSTRUCTOR IN NEUROLOGY AND NEUROPATHOLOGY IN THE UNIVERSITY OF PENNSYLVANIA; ASSISTANT NEUROLOGIST TO THE PHILADELPHIA GENERAL HOSPITAL.

It is not the purpose of this paper to consider minutely the histology of cerebellar growths, as this information can be obtained in any textbook on neurology. The pathological aspects of the various conditions which give the symptoms of cerebellar tumor will be considered, especially in a surgical sense.

It is difficult to make a satisfactory classification of such a subject, but the following plan will be adopted:

1. The ordinary tumors in their order of frequency, as glioma, tuberculoma, cysts, and so forth, of the cerebellum itself.
2. Growths of the surrounding regions giving cerebellar symptoms, as of the fourth ventricle, medulla oblongata, pons, and corpora quadrigemina.
3. Growths in parts besides those mentioned, giving cerebellar symptoms.
4. Abscess of the cerebellum.
5. Internal hydrocephalus, with symptoms of cerebellar tumor.
6. Cerebellar symptoms without any lesions.
7. Lesions of the cerebellum without any symptoms.

Excellent statistical studies of the frequency of the cerebellar and other cranial growths have been made, and without the desire to add to the already voluminous literature on the subject, it has been thought advisable to give a brief report of the brain tumors now in the neuropathological laboratory of the University of Pennsylvania, which is under the direction of Professor William G. Spiller. This collection has largely been accumulated in the last three or four years, and is from the services of Dr. Mills and Dr. Spiller, although in a number of instances specimens have been obtained from other sources.

Sections of at least seven other brain tumors were not considered, because definite knowledge of the location of the growths was lacking.

According to statistics tumors of the cerebellum are less frequent than of the cerebrum. Schuster, in a statistical table of some thousand cases of brain tumor, found 21.6 per cent. to be cerebellar. When the relative size of the cerebellum and the cerebrum is considered, it is probable that new growths are more frequent in the former.

Tuberculous growths are more common in persons below the age of twenty years, while glioma, sarcoma, and cysts of various kinds are more frequent in the adult. The frequency of fibroma, especially of the acoustic nerve, is becoming better recognized. Syphilitic tumors of the cerebellum are rare. Of the other forms of new growths, as carcinoma, lipoma, angioma, psammoma, and dermoid cysts, there are very few instances in the literature.

The lateral lobes of the cerebellum possibly because of their greater size, seem to be more frequently the seat of tumors than the middle lobe, although writers differ upon this point. Tumors within the middle cerebellar peduncle are rarely found, although a tumor within this peduncle is present in one of the specimens in the laboratory. Growths in the anterior and posterior cerebellar peduncles are also uncommon. The angle formed by the cerebellum, medulla oblongata, and pons is a favorite seat for new growths, these tumors growing either from within or upon the acoustic, facial, or trigeminal nerves, and frequently are fibromata.

Tuberculoma.—In 152 tuberculous brain tumors collected by Allen Starr, occurring in childhood, 47 were in the cerebellum. In the adult they are found with equal frequency in this region and in the pons and the cerebral cortex. They are nearly always multiple, and secondary to a tuberculous process elsewhere in the body. A tendency to symmetrical arrangement is also observed (Oppenheim). Their size varies from a small nodule to a large fist. Macroscopically, it is hard to distinguish a tuberculoma from a syphiloma. Both have poor blood supply and a tendency to caseate, the tuberculous growth to pus formation. Again, both have a tendency to grow

* From the Neuropathological Laboratory of the University of Pennsylvania.

from the meninges, although the tuberculous growths are found in the substance of the brain, and may have granulation areas and miliary tubercles about their border. It must be recalled, however, that syphilitic tumors of the cerebellum are rare.

The growth of a tubercle may be either rapid or slow. Tuberculous tumors may give no clinical symptoms. This has been explained by the slowness of the growth, the cerebellum gradually accommodating itself to increased pressure. Very recently, however, Raubitschek was able to demonstrate the persistence of the axis cylinders in tuberculous growths by Bielschowsky's method. This, as in multiple sclerosis, explains the persistence of function. Surgically, it is not advisable to operate upon these growths, as they are multiple and cannot be removed.

Glioma.—The cerebellum is a favorite seat for glioma. Five of our cerebellar growths were of such nature. Gliomata are almost always primary and single, although metastasis has been noted. The tumor may be as small as a cherry or as large as a hen's egg; it always grows from the brain substance itself, and is of slow growth. It is not sharply defined, but infiltrates into the brain substance, and it is difficult to tell it from normal brain tissue, although sometimes there is an increased consistence to pressure and there may be a slight swelling. The border zone of the tumor may present an increased number of blood vessels and there may be islets of new tissue.

Gliomata may be hard or soft, depending upon the excess of cells or fibrils, and have a yellowish white or reddish appearance. Cystic formation is very common, some authors believing that the whole tumor mass may disappear, leaving nothing but a cyst wall, and that it is necessary to examine microscopically the capsule to determine the gliomatous origin. Cysts form in the neighborhood of these tumors, and the surgeon may tap one of these cystic formations, believing it to be the only lesion present. It is wise, as Oppenheim has pointed out, to remove always a part of the cyst wall for microscopic examination. The fluid inside of these cysts may be whitish or bloody in character. Fatty, hæmorrhagic, and myxomatous changes occur in gliomatous tumors.

Microscopically, it is difficult to distinguish a glioma from a sarcoma unless a differential stain has been employed. There is some doubt as to the simultaneous occurrence of glioma and sarcoma, the so called gliosarcoma, some authors believing this to be impossible, as the former is of

ectodermal and the latter of mesodermal origin. Others believe that by metaplastic processes a sarcomatous structure may develop from neuroglial tissue. According to certain pathologists, a gliosarcoma should only be diagnosed where a sarcomatous, perivascular cellular mass is found within a glioma.

It can readily be understood from the slow growth and from its infiltrating character why clinical symptoms of brain tumor do not always appear, or not until late in the disease. Surgically, it is difficult or even impossible to remove completely such a tumor. Sections made from the specimens removed at the operation in Cases I and II of Dr. Mills and Dr. Frazier showed a glioma in each instance.

Sarcoma.—This form of brain tumor is about as common as the glioma, although in our experience sarcomata have been more frequently found. The growth may be small, flat, or nodular, or may be of large size. It is primary and usually solitary. Sarcoma always grows from the meninges, periosteum, or cranial bones, or from the pial covering of the blood vessels. It never grows from the brain substance, and therefore, unlike the glioma, it often compresses the brain tissue and may be distinct from it, although not infrequently it infiltrates the latter. Even when growing within the brain a distinct margin sometimes may be found, due to the softened area surrounding it. It is usually harder in consistency than a glioma, and is slow in its growth.

The tumor may soften or caseate. Myxomatous, hæmorrhagic, and cystic changes are not uncommon. Cystic changes are especially common in the cerebellum, not only in sarcomata, but also in gliomata. In one of Dr. Spiller's cases small sarcomatous masses were found in the walls of a cyst. If the fibrous tissue is very marked we have a fibrosarcoma.

Sarcoma may manifest itself as a diffuse multiple sarcomatosis. In an excellent article Spiller recorded two such cases and called attention

FIG. 1.—Sarcoma in left cerebellopontile angle. Small tumor in right cerebellopontile angle does not show in photograph.

to the rarity of this disease. He quotes Schlesinger, who subdivided the tumors under the head of multiple sarcomatosis into

(a) Diseases of the nervous substance and meninges,

(b) Multiple sarcomatosis of the membranes without sarcoma of the brain or cord, when it is (1) in the form of multiple small tumors, or (2) a diffuse sarcomatous infiltration of the membranes.

Of twenty cases recorded by Schlesinger, fourteen implicated the brain and cord or their membranes. "In nine of these fourteen cases cerebellar tumor was found, and in three the medulla oblongata was affected. It appears, therefore, that when the brain or its membranes are implicated in sarcomatosis, usually the structures of the posterior cranial fossa are affected, and that in about two thirds of the cases a tumor of the cerebellum is found."

In Spiller's first case a large sarcoma was found in the left cerebellar lobe, and in his second case a tumor was found in each cerebello-pontile angle, the larger one being on the left side, as shown in Fig. 1. Tumors were also found in this case in the Gasserian ganglia, pituitary body, floor of the fourth ventricle, right internal auditory meatus, and right jugular foramen, and numerous small tumors were found in the pia of the spinal cord.

(To be concluded.)

The Irritable Bladder.—Hirsch, in *Fortschritte der Medizin*, for October 1, 1904, states that the clinical foundation for this condition is the morbidly increased sensitiveness of the bladder in the region of the trigonum and the internal sphincter. The condition is determined by certain symptom complexes, very similar to but not depending upon, hyperæsthesia, and includes neuralgia, cystospasm, and the ordinary urinary trouble from mechanical causes. No pathological elements in this condition have as yet been found, with the exception of simple hyperæmia. There is sufficient trouble, however, from the continually recurring desire to empty the bladder, the generally increased reflex excitability, neurasthenia, and hysteria. The cause of this condition may reside in the bladder alone, or it may be found in a general hyperæmic condition of the genital organs, the rectum and the pelvic vessels. The diagnosis may be made by exclusion, all other troubles in the urogenital apparatus having been eliminated. This condition leads to a great many other morbid conditions and may finally become irremediable. In any event, it is extremely obstinate and involves constant annoyance from the desire to urinate or from hyperæmia. The treatment, so far as ordinary methods are concerned, has little that is valuable to recommend it.

THE DIAGNOSIS OF CEREBELLAR TUMORS.

By JOSEPH FRAENKEL,
NEW YORK.

The variety of lesions found in the posterior fossa of the skull is not met by an adequate exactness of diagnosis. A large number of cases of this kind are still catalogued clinically under the general heading of cerebellar disease.

It is true that to a great extent the diagnostic refinement has in this instance small importance for practical therapeutics. Theoretically it would appear that the posterior fossa of the skull could be reached by the surgeon. The difficulties are still considerable indeed, and there is ample room for improvement of technique.

Few instances of successful removal of growths from this locality are on record. It is obvious that definite knowledge of the nature, size, and location of the lesion will in some cases materially aid prognostication and therapeutic considerations.

Pathological conditions of different nature and character may arise in any of the tissues or structures of the posterior fossa; their nature, size, and duration will considerably complicate the clinical picture. Frequently an exact diagnosis will be impossible; particularly when the disease has lasted a considerable time, and the history does not reveal a clear picture of the early symptoms and sequence of events.

Primary lesions of the bone, meninges, basal nerves, cerebellum, pons, or medulla have been reported; aneurysms of the basilar and vertebral arteries and their branches, and other vascular lesions occur; localized syphilitic or tuberculous meningitis¹ is not common.

As a curiosity we may mention our observation of a case of compression of the medulla by an osteoma of the processus odontoides atlantis, and of a case of abscess of the pons, in consequence of chronic purulent middle ear disease.

From the clinical standpoint, these pathological conditions are easily separable into 3 groups:

1. Lesions originating outside the medullary structures of the posterior fossa, extracerebral lesions as it were; fractures, hæmorrhages, aneurysms, disease of the bone or meninges, remaining either outside of the medullary structures or invading them by contiguity.

2. Lesions originating within the medullary structures of the posterior fossa (pons, medulla, cerebellum)—intracerebral lesions: vascular lesions, tumors, abscesses; either strictly localized within, or invading the surrounding tissues by contiguity.

¹ Fraenkel *Journal of Nervous and Mental Diseases*, 1899, p. 427.

3. Lesions originating primarily in the basal nerves of the posterior fossa and invading the surrounding structures later.

Careful consideration of the intensity of the general symptoms and of the time of their appearance, will frequently give diagnostic aid. That headache, vomiting, and optic neuritis are early and obstinate symptoms in cases of cerebral lesions, is common experience. The opposite is true of pontine and medullary lesions.

The situation of the headache is of little diagnostic value; occipital headache is the rule. Superficial tenderness of the skull will occasionally indicate the side. It is frequently observed that the headache and vomiting, accompanying lesions of the posterior fossa, are most distressing in the morning after rising, or after a change of posture.

In syphilitic meningitis the headache is often liable to be nocturnal. The dizziness frequently observed in cases of disease of the posterior fossa, is clinically not unequivocal. It is difficult to decide whether it is more correct to interpret it in a given case, in the light of a focal cerebellar symptom, or to view it as a general symptom of increased intracranial pressure, or, finally, as denoting meningeal irritation.

In extracerebral lesions, that is in primary lesions of the bone and meninges or basal nerves, the headache will be less definite in character and location, and frequently absent for a long time. Vomiting and optic neuritis develop at a much later stage of the disease.

Seizures of various kinds are enumerated in the symptomatology of disease of the posterior fossa. General motor convulsions are rare, and when present are of little diagnostic value. Nothnagel's belief in the existence of an epileptogenous centre in the pons is not borne out by clinical experience.

Attacks of amyasthenia and general vertigo are frequent and express cerebellar embarrassment. Attacks of the Adams-Stokes's syndrome (disturbances of respiration and circulation with or without loss of consciousness) are not common. When occurring early in the disease they are more probably due to direct and, when late, to indirect interference with the functions of the medulla.

Trophic and visceral symptoms mostly accompany pontine lesions; sometimes bulbar, and very rarely cerebellar affections. To definitely ascertain the first symptoms is often quite difficult in cases of long duration. The importance of doing this can be hardly overestimated. As a rule the early symptoms, if unequivocally established, will greatly facilitate the localization.

Early symptoms of irritation of cranial nerves, particularly of the fifth or eighth nerve, are mani-

fested of great diagnostic significance, in suggesting extracerebral origin of the disease.

Deafness, general locomotor incoordination, disturbances of circulation and respiration, hemiparesis, or paralysis of conjugated ocular movements, introducing the disease, favor a diagnosis of the intracerebral origin.

Of the extracerebral lesions of the posterior fossa, those originating in the basal nerves deserve distinction for various reasons. Excepting rare metastatic or primary lesions of the bone, and the less rare localized meningitis, the solid lesions of the pontomedullocerebellar angle are due to primary tumors of the fifth or eighth nerve.

These tumors are most frequently neurofibromata, arising from the endoneurium or perineurium. The mentioned two nerves seem to have a particular predisposition, and the reasons therefore were discussed in a paper by Dr. Hunt and myself.²

This condition is apparently not very rare. In the course of four years we have observed eight cases of this character. The symptomatology is easily construed from the statements already made. The diagnostic characteristics are briefly as follows: Symptoms of irritation followed by symptoms of paralysis of the fifth or eighth nerve, to which later are added the symptoms of pressure of the surrounding structures of the posterior fossa.

Obstinate trigeminal neuralgia, tinnitus aurium, aural vertigo, Ménière's syndrome, later anaesthesia of the face or neural deafness, and finally generalized headache, vomiting, optic neuritis, cerebellar gait, hemiataxia, hemiparesis. Attacks of amyasthenia or of Adams-Stokes's syndrome are the most frequent symptoms.

Considering the fact that the neurofibroma is a slowly growing neoplasm, and that on account of its histological structure and frequent origin within the nerve, it slowly destroys the nerve fibres, it will be understood why the early symptoms are frequently vague, and why occasionally a considerable period of time elapses between the early symptoms and the development of the later ones.

In one of our cases there seems to have been an interval of 30 years from the time of the development of the growth in the acoustic nerves (bilateral acoustic fibroma) up to the time of the appearance of symptoms of brain tumor.

THE OCULAR SYMPTOMS OF CEREBELLAR TUMOR.

By G. E. DE SCHWEINITZ, M. D.,
PHILADELPHIA.

The ocular signs of cerebellar growth are chiefly concerned with changes in the fundus oculi, particularly the nerve head, and with anomalies of the external ocular muscles and the movements of the eyeballs.

I. PAPILLITIS, OR CHOKED DISC.

(a) *Frequency*.—In order to ascertain the percentage of choked disc or papillitis in cases of suspected intracranial tumor, Dr. John Weeks¹ has collected the reports of 677 brain tumors, and finds that those which involve the corpora quadrigemina give the highest percentage, namely, 100; next come tumors of the parietooccipital region, with a percentage of 87.8, while new growths of the cerebellum furnish a percentage of 87.2. In his list are the records of 164 cases of cerebellar tumor, and only 21 times was optic neuritis absent. In an analysis of intracranial tumors with respect to the existence of optic neuritis published by Edmunds and Lawford,² 23 cases of neoplasm of the cerebellum are reported, and in 20 of them optic neuritis was present, being absent only three times. It is not necessary to elaborate these statistics, because the fact would not materially be altered that with the exception of growths of the corpora quadrigemina, and possibly those of the parietooccipital region, cerebellar tumors yield the highest percentage of papillitis, or so called choked disc.

(b) *Character of the Neuritis and Nerve Head Changes*.—It is a matter of common observation that optic neuritis develops with rapidity in cerebellar tumors, indeed, with greater rapidity than when they are elsewhere situated. In the words of Mr. Gunn, intense double optic neuritis, with great engorgement of the papillæ and with surrounding retinal change coming on quickly, suggests a cerebellar growth. In addition to a papillitis of an intense type, that is, one having the characteristics to which the term choked disc is applied, a cerebellar growth may also originate a more moderate swelling of the nerve head, somewhat condensed in appearance and comparatively free from undue capillarity.

It is not possible to state exactly how much time must be consumed before the optic neuritis of cerebellar neoplasms is evident. As already stated, the development is usually a rapid one, and the neuritis may appear within a few weeks, or even a few days, after other signs of involvement of this

region are evident, for example, intense headache, vomiting, and vertigo. Sometimes longer periods of time are required before optic neuritis is discovered. In one of my cases with other well marked signs of cerebellar growth there was no neuritis; six months later there was well marked neuritis in one eye and intense papillitis in the other.

It not infrequently happens that patients come to ophthalmoscopic examination after the papillitis has already subsided and a postneuritic atrophy is present, or at a period when the swelling of the disc is rapidly disappearing and atrophy beginning. Optic nerve atrophy, without signs of preexisting neuritis, and blindness, unassociated with ophthalmoscopic lesions, have been reported.

It is well known that the papillitis of intracranial tumor is sometimes unilateral and that when there is a one sided optic neuritis, or a marked difference between the two sides, it is suggestive of the fact that the cerebrum is the seat of the growth, and, on the whole, in favor of the tumor being on the same side as the excess of neuritis. Less frequently unilateral neuritis occurs in cerebellar tumor. It was noted four times in 164 cases of the Weeks collection. Referring to this point Mr. Gunn³ writes as follows: "Taking the important analysis of 601 cases of tumor made by Dr. J. M. Martin, and paying attention to the relation between position, occurrence of optic neuritis, and difference of neuritis on the two sides, I find that there was unilateral neuritis (or excess) in 10 cases of frontal tumor, and in 8 of these it occurred on the same side as the tumor. In four cases of neuritis difference, in cases of temperosphenoidal growths, the one sided excess was always on the same side. Putting these together, we have the unilateral excess of neuritis on the same side as the tumor in 12 out of 14. The unilateral character of the neuritis was noted in 10 cases of tumor of the parietooccipital lobes and in the cerebellum. In 5 of these it was on the same side as the tumor and in 5 on the opposite side."

He further points out that a one sided difference of neuritis is more common in tumors of the cerebral lobes than in tumors of the cerebellum. In the collection before referred to it occurred in 20 per cent. of all of the cases of neuritis with tumors of the cerebrum, and in only about 3 per cent. of those associated with tumor of the cerebellum. I have not seen unilateral neuritis in cerebellar growth, although, as in the present collection, I have noted an excess of neuritis on one side as compared with the other.

(c) *Retinal Changes*.—It has been known since the observations of von Graefe, Schmidt, and

¹ Transactions of the Section on Ophthalmology of the American Medical Association, 1899.

² Transactions of the Ophthalmological Society of the United Kingdom, IV, 1884, p. 82.

³ Brain, XXI, 1898, p. 335.

Wegner, more than thirty years ago, that appearances exactly simulating those seen in retinitis albuminurica, particularly the so called macular figure, may be found in brain tumor. This stellate macular figure, in addition to the swelling of the nerve head, has been noticed with particular frequency in cerebellar tumors and has been the subject of comment especially by Dr. James Taylor and Mr. Marcus Gunn.⁴ While it is more common to find this stellate figure in cerebellar growths than in others elsewhere situated, it is not peculiar to them, and Mr. Gunn himself remarks that he has seen it in frontal tumors. One of the best marked examples in my own observation occurred in a growth which was certainly in the cerebrum, although its location was not proved by autopsy, and another excellent example appeared in a subcortical growth of the midregion of the brain which had pressed upon the optic tracts and produced hemianopsia, and which was removed by Dr. Hearn and Dr. Da Costa in the Philadelphia Hospital. I have also seen it in perfect degree in several cerebellar tumors, one particularly in the Orthopædic Hospital and another under the care of Dr. Mills and Dr. Frazier in the University Hospital, a full eye examination of which is recorded in the present paper.

Other retinal changes not significant of cerebellar tumor may also appear, for example, postneuritic atrophy, perivasculitis, areas of atrophy marking the position of former hæmorrhages, exudations and sclerotic alterations in the retinal vessels, if the patient has also been the subject of general arteriosclerosis.

(d) *Visual Acuity*.—It is well known that optic neuritis caused by intracranial growth is perfectly compatible with good visual acuity, but if the growth is situated in the cerebellum there is apt to be early great disturbance of vision, rapidly proceeding to blindness. Edmunds and Lawford referring to the frequency of blindness under these circumstances, compare it with the optic neuritis which occurs in tumors of the basal ganglia, which in their table yield next to cerebellar growths the highest percentage of optic neuritis, but in only five of the twenty cases was blindness present, as against nine which progressed to blindness in twenty-three cases of cerebellar tumor. Moreover, of the twenty cases with optic neuritis, seven were blind on admission to the hospital and two others became blind before death. They suggest that as cerebellar tumors are not so rapidly fatal as basal tumors, time is allowed for the neuritis to pass on to atrophy and to blindness.

Dercum⁵ in 1893 tentatively advanced the following explanation of early blindness in cerebellar growths: "The proximity of the quadrigeminal bodies naturally suggests itself as in some way explaining this blindness. A consideration of anatomy will show that if a growth be situated in the veriform process, especially anteriorly, and that if this growth continues to enlarge, it will sooner or later press upon the superior cerebellar peduncles; and very probably upon the quadrigeminal bodies themselves. Now if we recall the relation which the fibres of the optic tracts bear to the primary optic centres one can readily understand how, if pressure or irritation occurs at this point, a neuritis would be the consequence. Further, the irritation being direct, one can, perhaps, understand why the neuritis should be of a high grade; and finally, also, why this neuritis should be associated, sooner or later, with total blindness." Recognizing, however, that this hypothesis, especially in so far as it refers to the development of the neuritis, is unsatisfactory, Dercum has abandoned it.

Oppenheim⁶ thinks that upon the hydrocephalus which almost always accompanies in considerable degree tumors of the cerebellum, depends the decided choked disc and its prompt arrival, as well as the early amblyopia, to be followed later by amaurosis. According to him, the rapid, sometimes sudden, appearance of amaurosis is due to a compression which injures the chiasm and which is caused by a bulging forward of the floor of the third ventricle. A similar explanation is applicable to those cases of amblyopia and blindness without eyeground changes which have been observed by Curschmann, Gerhardt, and others. The optic nerve atrophy, which is sometimes noted in cerebellar disease without evidence of much preexisting neuritis, Oppenheim also attributes to pressure upon the chiasm.

It would seem, therefore, that the blindness may be explained in part by direct pressure from hydrocephalus, and in part by the compression of the optic nerve fibres and their subsequent atrophy owing to the high grade of engorgement edema, or to an actual neuritis. The relation which the destruction of the ganglion cells of the retina bears to this blindness requires further study, and it may be that their disintegration will account for some of the cases of early and even sudden blindness in cerebellar tumor associated with papillitis of marked degree.

(e) *Effect of Operation on Papillitis*.—In so far as the pathological examinations of cerebellar optic neuritis are concerned, they do not differ from those

⁴ *Transactions of the Eighth International Medical Congress*, Edinburgh, 1894.

⁵ *Journal of Nervous and Mental Disease*, 18, 1893, p. 683.

⁶ *Die Geschickliste des Gehirns*, by Prof. Dr. H. Oppenheim, Wien, 1896, p. 144.

which have been made in the optic neuritis of other intracranial growths, and it is not germane to the present topic to discuss this subject concerning which there is still much difference of opinion. In general terms, microscopical examination would seem to indicate that in a certain number of cases of papillitis, be they of cerebral or cerebellar origin, there is a true *engorgement edema*, and that the evidence of inflammation, in any decided degree at least, is lacking, while in other cases the inflammatory signs are marked. When the engorgement edema is the marked feature, the ophthalmoscope reveals the typical picture of choked disc. When, on the other hand, the inflammatory condition predominates, the elevation of the disc may be less marked and the process may extend to the surrounding retina. In other words, there is an *inflammatory optic neuritis*. Now, if one sees the case during the period of engorgement edema, before inflammatory exudates are present, naturally it is desirable to reduce the swelling of the nerve head. Horsley, Bruns, Erb, James Taylor, and many others have called attention to the fact that there may be a subsidence of the optic neuritis after operation undertaken with a view to the removal of an intracranial tumor, even when the tumor was not removed, and Taylor has recorded a number of examples of this character. Certainly, as Horsley points out, removal of pressure is one of the factors in the reduction of optic neuritis in intracranial tumors, and as Hill Griffith has said, should there be recovery after blindness with optic neuritis by trephining, the indications are that the optic nerve condition was produced by pressure.

Saenger⁷ reports prompt subsidence of double sided choked disc after palliative trephining for cerebellar growth and advises this operative procedure in tumors which cannot be removed in order to relieve pressure symptoms and especially to avoid impending blindness. In seven cases of double choked disc he has noted a disappearance of this condition after such trephining. In two of the patients described by Dr. Mills in the present paper and trephined by Dr. Frazier, with removal of the growth, there was decided and comparatively prompt subsidence of the choked disc. In one of these blindness occurred, but the patient was practically blind when she was trephined. In the other the visual acuity before the operation, which was good, that is, two thirds of normal, has been maintained until the present time and the neuritis has partly subsided.⁸

If it be true, as Merz declares, that increased

intracranial tension alone is sufficient to produce choked disc, provided this tension shall be maintained uninterruptedly for a certain time, and if further it is true, as would seem from reported cases, that there is reduction of such tension by trephining, even where the tumor is not removed, then certainly Saenger's advice that such palliative trephining should be performed early, especially in the choked disc of cerebellar tumor, which is almost sure to produce blindness, is sound and should be followed.

II.—ANOMALIES OF THE OCULAR MUSCLES AND OF THE MOVEMENTS OF THE EYEBALLS.

Owing to the anatomical relations of the cerebellum, tumor formation in this region may bring about involvement of certain of the cranial nerves, particularly the facial and the auditory. In so far as the eye muscle nerves are concerned, the abducens is by far the most frequently affected, and convergent paralytic strabismus with involvement of one or both abducens nerves is not an unusual symptom in cerebellar growth. In a case reported by Saenger with gliosarcoma of the left cerebellar hemisphere, there was double abducens paralysis with marked thinning of the nerves, and in a similar growth recorded by Sander the abducens paralysis was explained by finding a lesion in its nucleus. Wernicke states that sixth nerve paralysis is most apt to be present as a distant symptom when the tumor is situated in the cerebellum. In this respect the sixth differs from the third nerve, which, as Swanzy has well shown, is more likely to give distinct symptoms with a lesion of the cerebral hemisphere.

In one case recorded by Dr. Mills in the present paper where the cerebellum and the pons oblongata were exposed and a cyst was discharged, there was paralysis of the branch supplying the left levator palpebræ and the left inferior rectus. According to Oppenheim ptosis and reflex immobility of the pupil without loss of sight and paresis of accommodation have been observed, and he quotes Mackenzie, Bruns, and other authors as having observed a more or less complete ophthalmoplegia.⁹ A rare ocular muscle palsy is one that affects the superior oblique, that is to say, the trochlearis is involved. Referring to the aetiology of these conditions, Oppenheim remarks that the paralyses must depend upon a lesion of the nerve trunks themselves, or upon pressure exerted on the region of their nuclei. When ophthalmoplegia is evident, it may be explained by an involvement of the corpora quadrigemina.

Bruns,¹⁰ referring to the difficulty of telling on

⁷ *Munch. med. Wochenschr.*, XLVIII, 1901, p. 2.

⁸ Since this sentence was written the patient has been seen, and the vision has begun to fail and a partial ophthalmoplegia has developed; evidently there has been recurrence.

⁹ In one case at present under my observation there is paralysis of all external ocular muscles except the inferior recti, which are beginning to be involved, and the superior obliques.

¹⁰ *Neurologisches Centralbl.*, 18, 1899, p. 519.

which side of the cerebellum a tumor has its situation, speaks of the help obtained in this respect when certain nerves are paralyzed, for example, the trifacial, the facial, and the auditory, and refers as a frequent symptom to the presence of associated paralyzes of ocular movements which then appear toward the side of the tumor. So frequent are these paralyzes that in large tumors of the cerebellum Bruns considers them to be constant.

Oppenheim, discussing the same subject, remarks that this symptom, that is, a paralysis of associated parallel movements of the eyes toward the side of the tumor with deviation of the eyes toward the opposite side, depends upon a one sided compression of the pons. It is, therefore, the rule that the eyes of these patients cannot be moved toward the side of the tumor. He warns, however, that the symptom cannot be absolutely trusted, inasmuch as in two cases under his own observation there was paralysis of associated parallel movements toward one side when the vermiform process was the part involved in the tumor formation.

According to Gowers, an unsymmetrical position of the eyes, one directed upward and inward and the other one downward and outward, has been observed as a rare symptom of tumor of the middle peduncle of the cerebellum.

Nystagmus is almost always present in cerebellar tumors. It may be rotary or vertical, but is most frequently lateral. Sometimes it is not observable when the gaze is directed forward but develops at once in right or left l  voversion.

It would seem also that in a certain number of cases the nystagmus is evident only when the eyes are turned toward the side on which the tumor is situated, and, indeed, that such nystagmus may be the sole ocular sign of the cerebellar growth. For example, Pineles¹¹ observed in a patient with normal eyegrounds nystagmus only when the eyes were directed to the left. Post mortem examination revealed a walnut sized tubercle in the left cerebellar hemisphere, the middle of the lobus quadrangularis being also involved. This development of nystagmus when the eyes are rotated toward the side of the tumor has been commented upon by a number of observers. It has been noticed by Mills, Spiller, and by myself in several cases which we have examined together. In place of a true nystagmus, a nystagmoid movement is often observable when the eyes are turned from side to side, particularly if there is an associated paralysis of the external rectus. There is no doubt that nystagmus may be regarded as a direct cerebellar symptom. It has also been referred, according to Arnheim who

quotes Russell in this respect, to a paralysis of the ocular muscles.

That double optic neuritis, internal strabismus, and nystagmoid movements on looking both to the right and to the left, must not, however, be regarded as characteristic or pathognomonic of cerebellar tumor, is evident from a case recorded by Bramwell,¹² in which these symptoms were present and the lesion consisted of a dilatation of the ventricles, especially of the fourth ventricle, the result of a previous meningitis and an obliteration of the foramen of Magendie. The oscillation of the globes in blindness from cerebellar tumor must not be confused with true nystagmus.

There is nothing characteristic in the *pupil reactions* in disease of this region. If there is blindness and loss of light perception, there is naturally loss of the light reflex, while, if light perception remains, this reflex is preserved.

So, also, the field of vision furnishes no characteristic changes. It may be perfectly intact or concentrically or irregularly contracted, according to the degree of atrophy existing in the optic nerves. In some cases there seems to have been hemianopsia, but probably only a contraction of the visual field resembling this phenomenon due to atrophy in the optic nerve, or alteration in the ganglionic cells of the retina. It is of course conceivable that hemianopsia could occur as an associated symptom if with the cerebellar growth there were other lesions which pressed upon some portion of the optic pathway.

Lectures by the Phipps Institute Staff.—The Phipps Institute for the Study, Prevention and Treatment of Tuberculosis has outlined a course of popular lectures on Tuberculosis to be delivered by members of the staff before such professional and lay societies as shall request them. Many lantern slides have been prepared for the illustration of these lectures. Recently Dr. A. P. Francine lectured before the Pittsburgh Nurses' Association on The Care and Treatment of Consumptive Patients. Dr. D. J. McCarthy delivered a lecture on the same topic at the Deaconesses' Home, and Dr. Horace L. Carncross spoke before the Glassblowers' Union of New Jersey at Woodbury. In the near future Dr. Ward Brinton will lecture to the textile workers in Kensington, and Dr. McCarthy will speak at Oil City. At the meeting of the Associated Health Authorities and Sanitarions of Pennsylvania in Harrisburgh in the second week of February the Phipps Institute staff will give a course of lectures and an exhibition of the work of the institute. At the same time similar exhibitions will be made by the Pennsylvania Society for the Prevention of Tuberculosis and by the Free Hospital for Poor Consumptives at White Haven.

THE FUNCTIONS OF THE CEREBELLUM.

By EDWARD LODHOLZ, M. D.,

PHILADELPHIA,

DEMONSTRATOR OF PHYSIOLOGY, UNIVERSITY OF PENNSYLVANIA.

Probably there is no part of the nervous system that differs more in size and functional importance, in closely allied species, than the cerebellum. Its development depends to a great extent upon the means of orientation of the animal. Reptiles possess a cerebellum functionally less active than swimmers, and in these it is less developed than in birds. Indeed in this animal which is capable of going through the most complicated movements of all animals the cerebellum is relatively enormous. However, the size is not always proportionate to the variety of movements. In the frog, which is capable of complex coordination, the cerebellum is relatively small. It is an unexplained anatomical fact that in birds the lateral lobes are absent, whereas in apes and man they are quite large.

Possibly no one has given so much impetus to the study of this part of the nervous system as Flourens (1). Practically all his experiments were performed upon pigeons, animals which show marked effects following the removal of parts of the cerebellum. Many of the phenomena here observed can be of but comparative interest to the student of human physiology. For this reason the work of Luciani has done much to further our knowledge of the function of the human cerebellum. He experimented upon dogs and monkeys, animals in which the cerebellum is more closely allied to the human cerebellum than that of pigeons.

So early as 1809 Rolando (2) removed portions of the dog's cerebellum, and several other physiologists studied the mammalia previous to Luciani's time, but none was able to surmount the tremendous technical difficulties necessary, for instance, to remove the whole cerebellum and keep the animal alive for a considerable period after the operation.

Luciani (3) showed the immediate symptoms differed very much from those which subsequently developed. If the narcosis is not too deep, and the loss of blood inconsiderable, the more important symptoms which immediately follow removal of the cerebellar cortex, are extreme restlessness; pleurosthenos, the concavity being toward the operated side; tonic stretching of the fore extremity on the homonymous side; clonic contractions of the other three extremities; and spiral twisting of the neck with the head turned toward the well side. Nystagmus and strabismus are present, the eye of the side operated upon being drawn down and inward, that of the well side up and out. If the animal at-

tempts to stand, he falls to the side of the lesion and rolls in the same direction.

When the whole cerebellum is removed there is marked restlessness and irritability of the animal; the head is drawn back, and the animal tends constantly to move or fall backwards. There is convergence of the eyeballs. If the wound remains aseptic these symptoms last from eight to ten days when they generally ameliorate, the tonic spasms become clonic or oscillatory, the animal is able to walk with less difficulty, and the tendency to roll from side to side or fall backward is less marked. Long before the animal learns to walk he is able to swim. This fact, first described by Luciani, has great physiological importance. The last symptom to disappear is opisthotonos.

The symptoms which occur with constancy after removal of the cerebellum give us but little information as to the exact rôle this part of the nervous system plays in the intact cerebrospinal axis. Wundt states that "the functions of the cerebellum belong to the darkest part of the central nervous system." The truth of this statement becomes more apparent when the multitudinous connections of the cerebellum with other portions of the brain and spinal cord are considered.

The old idea that the cerebellum has distinct functions independent of its connection with the rest of the cerebrospinal axis is rapidly disappearing.

The centre for coordination has been located in the cerebellum by Flourens, and the symptoms which follow ablation of a part, or the whole of the cerebellum seem to substantiate this assertion. However, cases have been recorded in which a large portion was congenitally absent associated with normal ability to execute coordinate movements.

Total ablation in animals is always followed by an amelioration of the symptoms after varying intervals of time, and eventually incoordination entirely disappears.

When the cerebellum is inactive it appears that cells in other parts of the nervous system are capable of performing the functions normally assigned to the cerebellar cells. The experiments of Ewald (4) and Luciani confirm this statement. They demonstrated that if compensation was completely established after partial cerebellar destruction, a return of symptoms would appear if certain cerebral motor areas were destroyed. The symptoms never reappear after the second operation.

A close functional relation has been found to exist between the semicircular canals and the cerebellum. Total destruction of the canals is followed by symptoms identical with cerebellar ablation. Stefani (5) found degeneration of Perkinje's cerebellar cells

after removal of the semicircular canals. From this the inference may be drawn that the canals are the peripheral organs and the cerebellum is the centre. Lange, a student of Ewald, found when the semicircular canals were removed from a decerebellarized animal, in which full compensation had been established, that the characteristic symptoms appeared such as are observed in a normal animal following destruction of the canals. Stefani concludes that the semicircular canals functionate not only through the cerebellum, but also through other parts of the nervous system. Luciani thinks these, and other experiments, disprove the belief of Magendie (6) that the cerebellum is the centre of static and dynamic equilibrium. He believes it does play an important rôle in the maintenance of equilibrium, and agrees with Galio (7) that we move in space by the aid of impulses coming from the special senses.

The results obtained from excitation of the cerebellar surfaces have added to some extent to our knowledge of the influence of the cerebellum upon nervous activity. It is a mooted question whether ablation produces symptoms the result of stimulation consequent to the trauma of the operation, or paralysis due to destruction of the cells. Ferrier (8) showed that unilateral burning of the cerebellum produced symptoms on the opposite side of the body to those following ablation. But this method is unscientific, for it is impossible to determine whether symptoms are due to stimulation or depression.

Electrical stimulation properly applied eliminates depression as a factor. A recent work by Lewandowsky (9) has shown that the electrical current produces results differing from those following ablation. When weak currents were applied to the cerebellum the following symptoms were noted: Restlessness; evidences of vertigo; lateral movements of the head; or the animal assumed a recumbent position and placed the head between the front paws. Strong currents caused curvature of the spinal column, when the left side was stimulated the concavity was toward the right side, the dog always fell toward the right. Occasionally nystagmus was observed. When the current was broken the movements occurred on the other side, but were decidedly weaker. It will be noticed, as Lewandowsky states, that the symptoms following stimulation are on the opposition side of the body to that produced by ablation.

Sherrington (10) reports a very interesting phenomenon following stimulation of the cerebellum. He discovered in decerebrate rigidity, a condition of long maintained muscular contraction following removal of the cerebral hemispheres, that inhibition

can be produced by excitation of the anterior (cerebral) surface of the cerebellum. He demonstrated that faradaization caused a relaxation of the muscles of the neck, head, and lower limbs, especially on the same side. He concludes that stimulation of the cerebellum "cannot only excite contraction of the muscles, but can inhibit contraction." However, the exhaustive studies in cerebellar ablation and stimulation have not given us very satisfactory knowledge of how this organ normally functionates, although many errors have been corrected and new facts added.

The teaching of the Gall school that the cerebellum has a sexual function has been disproved by Bouillaud, Luciani, and others. These investigators demonstrated that impregnation and birth of offspring would occur in an animal from which the whole cerebellum was removed.

Flourens was the first to locate in the cerebellum the centre for coordinated movements.

Luciani demonstrated that coordinated movements returned in animals from which the cerebellum had been removed.

The teaching of Rolando that the cerebellum was essentially motor has been modified by Dalton (11), Luys (12), Mitchell (13), and Luciani. These authors consider it an organ in which motor impulses are strengthened. Removal of the organ causes muscular weakness, which was described by Luciani as due to three factors: Asthenia (weakening of muscular energy), atonia (lessening of muscular tone), and astasia (uncertain and unsteady movements).

That asthenia is present is shown by the fact that animals with unilateral ablation swim toward the crossed side, but walk toward the same side. Astasia is represented by the intention tremor which develops at varying lengths of time after removal of either part or whole of the cerebellum. Atonia can be readily detected by the feebleness of the muscles which becomes manifest after the disappearance of the primary spasm.

Many physiologists have defended the theory of Lussana (14) that the centre for muscle sense is located in the cerebellum. The vertigo frequently present suggests a sensory function. But human beings with atrophy of the cerebellum still possessed a normal amount of muscle sense. Luciani's careful work has gone far to disprove the existence of such a centre in the cerebellum. A critical study of the theories advanced to explain the normal functions seem too inadequate to account for all the phenomena. It appears conclusive that the cerebellar cells are continually exerting an influence upon other nerve centres, but with reference to the

true nature of this action nothing is known with certainty.

REPORT OF A CASE OF CYST OF THE CEREBELLUM.

By JOHN M. SWAN, M. D.,

PHILADELPHIA,

PATHOLOGIST TO ST. MARY'S HOSPITAL.

A girl, aged 18 years (No. 1735), was admitted to St. Mary's Hospital in the service of Dr. M. H. Fussell on December 5, 1904, complaining of severe headache. The family history obtainable was not very satisfactory. The patient's father was living, apparently in good health; her mother was living but was addicted to the use of alcohol. One brother and one sister were living and apparently well.

Previous History.—Aside from the memory of an attack of chickenpox in childhood, the patient was sure she had never been sick in bed. She was quite positive that she had never had a cough or night sweats. She had noticed some morning expectoration. Menstruation had begun one year before and had been normal.

The present trouble began nine weeks before with severe frontal headache and weakness, for which she had to go to bed. Even a week before, she had had headache all the time. Since going to bed she had vomited from once to three times a day and on one occasion she vomited blood. Her bowels had been constipated; there was severe pain in the back and in the left leg. When first taken sick the patient had several chills.

On admission the patient complained of constant headache; it was discovered that she was blind in the right eye. She was a rather anæmic white girl, with short, blond hair. The face was the site of an eruption appearing like acne and there were many acne pimples on the chest and back. The pupils were dilated, the right more than the left, and re-

acted to light and accommodation. Nystagmus was present. There was paresis of the right external rectus muscle and the patient could not count fingers correctly with the right eye. The tongue was coated and protruded to the left. The teeth were covered with sordes. There was no enlargement of the lymphnodes. There was no paresis of the muscles of the face. There was some stiffness in the muscles of the neck and of the back and some stiffness in the muscles of the extremities. There was no difference in the grip of the two sides of the body. The plantar reflexes and the knee jerks were absent; there was no clonus; and no evidence of the presence of Babinski's sign; but Kernig's sign was present on both sides of the body. The temperature was 99°, the pulse 88 and the respirations 20 per minute on admission. Examination of the lungs gave no abnormal signs, except a slightly higher pitched percussion note at the right apex than at the left. The apex beat of the heart was neither visible nor palpable. The area of cardiac dulness was bounded by the third interspace, the left edge of the sternum, the mid-clavicular line, and the fifth interspace. There were no adventitious sounds but both diastolic sounds at the base of the heart were accentuated. The liver and the spleen were normal. There were no areas of abdominal tenderness.

Urine Examination.—Color, amber; specific gravity, 1026; reaction, acid; sediment, flocculent. Microscopically, leucocytes and amorphous urates were present; no casts were found. Chemically, albumin and sugar were absent.

Blood Count.—Erythrocytes, 5,980,000; leucocytes, 12,640; hæmoglobin, 70 per cent. No differential count was made.

The patient had no convulsions. During her stay in the hospital she complained constantly of headache and pain in the back of her neck. She did not sleep well. She died suddenly on December 23, 1904, between 4 and 5 a. m.

The following examination of the ocular condition was made by Dr. William Zentmayer, ophthalmologist to the hospital. Right eye: Pupil 6 mm., does not respond to direct light stimulus but does respond in consensual action. Slight limitation of outward excursion of right eye; but during rest there is marked convergent squint of the right eye. The ophthalmoscopic examination disclosed intense choked disc with hæmorrhages. The disc could be located only by the convergence of the vessels; its summit being seen with about + 8 D. There were numerous hæmorrhages and spots of fatty degeneration of the retina below the fovea. The right eye was blind. Left eye: Pupil 5 mm. Choked disc but not so prominent as in the right eye. Vision $\frac{1}{60}$. Candle field good.

Autopsy Record.—The autopsy was made December 24, 1904, 33 hours after death. Clinical diagnosis, tuberculous meningitis. Pathological diagnosis, cyst of cerebellum, tumor of cerebellum, congestion of the cerebral and spinal meninges. Histological diagnosis, degenerative cyst of the cerebellum, papillitis, congestion of the chorioid coat of the eye, acute retinitis, degeneration of the optic nerve. Cause of death, undetermined.

Permission was obtained for an examination of

the brain and the spinal cord only. The body was that of a well nourished white female, apparent age 18 years. Post mortem lividity unusually well marked. Post mortem rigidity moderate. *Spinal cord*: the dura was somewhat congested. On opening the dura the vessels of the pia were seen to be somewhat injected. There were no tubercles. In other respects the cord appeared to be normal. *Brain*: on opening the skull the internal table was seen to be eroded and finely granular in appearance. The dura was congested. On cutting the tentorium cerebelli on the right side a large quantity of clear, pale serum containing flocculi escaped. On delivering the brain the right hemisphere of the cerebellum was seen to be the seat of a large cyst which had almost entirely replaced the cerebellar substance on its ventral surface. The wall of the cyst was smooth and apparently composed of white matter. Projecting on the surface of the hemisphere there was a round tumor which was gelatinous at its peripheral portion, but more firm at its attached base.

The brain was not dissected but appeared to be normal on the surface.

The histological examination was made in the McManes Laboratory of Pathology of the University of Pennsylvania (No. 359). Sections were made (1) from the free portion of the tumor; (2) from the base of the tumor; and (3) from the posterior pole of the right eye. The tissues were embedded in paraffin and stained with hæmatoxylin and eosin.

The free portion of the tumor was composed principally of a fragmented, friable matrix which stained fairly well with eosin, but which was poorly stained in many places. It was more granular than fibrillar in appearance and in places entirely structureless and hyaline. Embedded in this matrix were relatively few cells. Some of these cells were round with multiple nuclei; others were spindle shaped and very deeply stained; and still others were somewhat stellate in outline and showed more than one nucleus. There were some deep blue staining

masses, which were sometimes lobulated and which resembled corpora amylacea somewhat. They showed no concentric lines, however, and, on account of their deep staining, suggested calcareous degeneration. The blood vessels were surrounded by large, perivascular lymph spaces and their walls were the seat of an inflammatory process which in some instances obliterated them.

Section from the base of the tumor mass showed a tissue on the side next to the free surface of the tumor which had much the same appearance as that already described. It was not so fragmented, however, but it showed the same absence of fibrillæ and the same granular appearance. The blood vessels in this portion of the tumor were shrunken, the perivascular lymph spaces were relatively much increased in size, the walls of the vessels were thickened and their lumina distorted. The cells were less clearly stained and appeared to be in process of degeneration. Many degenerating nuclei were seen. In the molecular layer of the cortex the same change was to be seen and the friability of the tissues was very marked. The cells presented the same characters as those already described. The cells of Purkinje were fewer than normal, and those that persisted were poorly stained. The cells in the granular layer of the cortex were numerous but showed degenerative changes and the intercellular substance was also granular as already described. The blood vessels showed the same changes.

Section of posterior pole of right eye showed endarterial changes in the sclera, marked congestion of the chorioid vessels, and marked fibrosis of the retina. The inner surface of the retina was covered over with loose fibrous layer, thickest close to the optic papilla, and diminishing toward the equator of the eye. This tissue was rich in new blood vessels and contained numerous fibroblasts. The looseness suggested separation by hydropic infiltration. The optic papilla was prominent. The optic nerve was completely degenerated, no fibres having been found after fairly careful search. It was the seat of marked fibroid changes. The subarachnoid space was distended and occupied by young, loose, fibrillar tissue and a granular, eosin staining substance which was probably fibrin.

Interpretation.—The tumor was probably a portion of the cerebellar substance which had not yet undergone complete degeneration. The cyst was probably due to a hydropic degeneration of the cerebellar substance due to an obliterating endarteritis. There were no characteristic appearances of syphilis in this process, unless the vascular changes be so regarded.

Therapeutical Notes.

Menthyl Valerianate.—Menthyl valerianate has been found to be an excellent prophylactic against seasickness. K. Köpke, in a treatise on seasickness, recommends this preparation on the grounds that, though not absolutely infallible, it yet rarely fails to act. In the early stages of the sickness it is best taken in 10 to 15 drops on a lump of sugar. If this dose should not have the desired effect, it may be repeated after half an hour, with observation of the strictest diet.

The Treatment of Syphilis at Aix-la-Chapelle.—Anton Levien, in a communication on this subject to the *Practitioner*, for July, 1904, writes: The details of the "cure" are as follows: After rising in the morning between 7 and 8 o'clock, the patient takes two or three glasses of sulphur water, each of 200 grammes, with the addition of salts, which are prepared in the factory of the Aix-la-Chapelle natural spring products. Patients who are fairly strong then immediately take their bath, while weaker patients and more especially those suffering from affections of the central nervous system take a light breakfast and wait for their bath until two hours later. The temperature of the bath averages 95° to 98° F.; but those with nervous diseases or alterations of the arteries are not allowed to take baths warmer than 92° to 94° F. The duration of the bath varies from 5 to 20 minutes, according to the strength of the patient. In suitable cases which can endure a hardening process, cooling douches or irrigations are used in addition to the baths. After the bath the patient rests for 20 or 30 minutes, care being taken that he does not perspire too freely in the interim. Then, after the patient has had his breakfast (I am referring now to the more robust cases) he is inuncted. The process is carried out as follows: With the naked hand an experienced masseur rubs the requisite quantity of 33 per cent. blue ointment evenly on to the skin for a period of 20 minutes (hairy patients are previously shaved to avoid folliculitis). The following parts of the body are subjected in turns to inunction: On the first day the legs are rubbed; on the second, both thighs; on the third, the back; on the fourth, the abdomen and flanks; and on the fifth day the arms. These inunctions are repeated again and again in that order until the requisite number has been attained. Of course the inunctions may be so intensified that a greater extent of the surface of the body is daily smeared with a somewhat larger quantity of the ointment.

The ointment thus rubbed in is not removed with the towel after the bath on the following day, and thus every part of the body is at once exposed to the action of the unguentum cinereum until each section is again prepared for a fresh inunction. This preparation is effected by means of scrubbing with soap and water at a high temperature. The ordinary temperature of the water has no effect upon the ointment, which liquefies only at 113° F.

In the rubbing, we are careful to avoid the axilla and the region between the scrotum and the thigh, because eczema might easily be set up in these situations. It is also essential to avoid pressure on superficial bones, such as the shins and ribs. I generally order a glass of the thermal water to be taken both before the mid-day meal and before supper, as I find this has a stimulating effect on the appetite. During the cure, the teeth must be cleansed of morsels of food after each meal by means of a soft tooth brush, with a tooth paste of salol and chlorate of potassium. The mouth, also, must be rinsed with a solution of aluminum acetotartricum every half hour.

NEW YORK, SATURDAY, FEBRUARY 11, 1905.

OUR "SYMPOSIUM" ON TUMORS OF THE CEREBELLUM.

In this issue we present the greater portion of a notable collection of original communications dealing with various aspects of the subject of tumors of the cerebellum. The authors are such well known men as Dr. Charles K. Mills, Dr. Charles H. Frazier, Dr. T. H. Weisenburg, Dr. G. E. de Schweinitz, Dr. Edward Lodholz, and Dr. John M. Swan, of Philadelphia, and Dr. Charles L. Dana and Dr. Joseph Fraenkel, of New York. Our readers will observe that the clinical element figures largely in these articles, but the contributions to the casuistics of the subject are not dissociated from that systematic consideration which one would expect from such thoughtful writers.

Necessarily a "symposium" of this character takes up a great deal of space, but we are sure that our readers in general will appreciate the grouping of so many authoritative utterances on a theme of such interest, and we are confident that those of our contributors whose articles are unavoidably kept back for a short time in order that we may produce the cerebellar tumor papers in an appropriate aggregation will readily concede that it is for no light reason that we countenance the delay. To mass a number of essays on a single topic, dealing with it from various

points of view, is to exemplify in literature that correlation which, as applied to college teaching, we commended in our issue for January 28th. And it is this feature that constitutes the strong point of a "symposium," putting it, as regards directness of interest, quite on a par with the report of an oral discussion, to which indeed it is superior in the item of more mature elaboration than can be looked for in extemporaneous speech, however carefully the fundamental points of the latter may have been worked up in advance. We are persuaded that an occasional "symposium" of the kind which we are now presenting is a peculiarly valuable feature of the periodical literature of medicine.

We believe that we shall be able to conclude this "symposium" in our issue of February 18th by publishing the interesting case reports of Dr. Mills, Dr. Frazier, and Dr. Weisenburg, together with two illustrations belonging to the last communication. We regret that the space at our disposal does not allow the publication of the papers in a single issue, but we feel that our readers will forgive the extension of this valuable contribution to modern surgery to a second number.

THE STARVATION TREATMENT OF OBESITY.

An interesting report on the treatment of obesity by reducing certain elements of the diet was presented at the Seventh French Medical Congress by Dr. Maurel, professor of experimental pathology in the University of Toulouse. Extracts from the report are published by Dr. Maurel in *Médecine moderne* for November 2d. The author seems to have had a large and satisfactory experience in the treatment of obesity, and his success is doubtless owing in great measure to his avoidance of the fault of pushing a pet treatment to extremes. The report deals with many aspects of the reduced diet treatment, and much scientific detail as to the rationale is brought out, but it is with a few practical points that we must here content ourselves.

One of these points relates to the wisdom of intermitting the treatment on occasions. Watchfulness, says M. Maurel, must always be exercised in the management of dietetic reduction; the patient must not be left to follow the course blindly, even when an energetic initial lowering of the amount of cer-

tain articles of food has accomplished a definite and gratifying result. At least as often as once in two weeks, whether there are complications or not, the condition of all the organs should be ascertained. If any of them are found at fault, it is often well to advise such relaxation of the rigid dietary as to enable the organism, so to speak, to adjust itself to new conditions, simply holding fast for a time to that which has been gained, without trying to push the cure.

Flaccidity of the skin is one of the chief occurrences that should call for a pause. In persons past middle life the retractile power of the skin is no longer such as to enable it to follow the reduced volume of the underlying tissues. An unpleasant flabbiness is the result, especially noticeable in the face, though to a considerable extent it shows also in the limbs and in the abdominal wall. When this state of things is observed, it is well to curb the rigor of the treatment until the skin has had time to retract upon the subjacent parts. Moreover, it is not always wise to push the treatment to the point of reducing the flesh to a theoretical normal; it is better to aim at a moderate reduction.

DR. BEVERLEY ROBINSON ON PNEUMONIA.

Pneumonia in all its forms is a disease so prevalent and of such a serious character that contributions to our knowledge of its management are always of value, particularly when they come from so conservative an observer as Dr. Beverley Robinson. Dr. Robinson has recently issued a pamphlet containing revised reprints of three articles written by him during the last ten years, and we feel sure that study of it will strengthen many a practitioner in his efforts to prevent the disease or to guide his patients toward recovery.

As regards the infectious nature of pneumonia, it is interesting to note that the short space of a little more than three years which elapsed between the original publication of his first article and that of the third was sufficient to make him a far more pronounced adherent of the infection theory. At the beginning of this period he was inclined to regard the disease as infectious only in certain instances and under certain circumstances, but at its close he says: "Pneumonia, or lung fever, should be classed among the infectious diseases. It is dis-

seminated by contact. It is taken by the attendants who nurse the patient and who breathe more or less constantly the contaminated air of the sick room filled with his expired breath, which is frequently the great carrier of the infection."

Considerable attention is given by Dr. Robinson to the prevention of the disease. Remarking that the *Micrococcus lanceolatus* is one of the least tenacious of life among the pathogenic microorganisms, and that it does not thrive in an acid medium, he recommends the frequent use of acid mouth washes in times when the disease is prevailing, though he is careful to add that, in view of the deleterious action of acids on the teeth, he does not approve of their employment at other times. Of almost equal importance with prophylaxis is prompt treatment at the outset of the disease, and among the most efficient measures for that purpose, he thinks, is the inhalation of the vapor of creosote. We infer that he regards this method of employing creosote as sufficient, so far as that particular drug is concerned, throughout the course of the illness. Used in this way it does not derange the digestion, and he does not find its odor objectionable. It is to be added to the water that should be constantly converted into steam in the patient's room.

As regards the advisability of removing a patient to a hospital, Dr. Robinson, while realizing the advantages of hospital treatment, judiciously balances them against the dangers that may be incurred in individual cases by the exposure, nervous shock, etc., incident to the transfer. If the patient is still in a condition to understand the advantage of his being in a hospital, if the hospital is not too far away, and if the means of transportation are satisfactory, it will be well to make the change; otherwise it had better not be made. Naturally a private room or at least a small ward is to be preferred to a large ward.

In addition to what we have here had space to mention, Dr. Robinson treats in a most judicious manner of the use of opium, coca, strychnine, and alcohol in the treatment of pneumonia. Particularly worthy of commendation, it seems to us, is his insistence on the employment of spirits and wines of the best quality when alcoholics are to be given. He administers a well deserved rebuke to those hospital authorities who are governed by parsimony in obtaining supplies.

CHLOROFORM VAPOR AND THE FLAME OF ILLUMINATING GAS.

Although it has been observed on various occasions that it is not safe to administer chloroform in the neighborhood of a gas flame, yet this fact does not seem to prevent the recurrence of accidents, many of which are serious and some of which are fatal. The danger is not on account of the chance of an explosion, as in the case of ether, but because the vapor of chloroform is decomposed, with the production of irritating and very poisonous compounds which, being gases, are inhaled by the patient and by all persons in the room. It was formerly supposed that the bad effects were due to the liberation of chlorine and hydrochloric acid, which are very irritating to the mucous membrane of the respiratory passages, but not particularly poisonous in any quantity in which they are likely to be inhaled. It has also been held that the poisonous effects must be due to inhalation of carbonic oxide, either from leakage of illuminating gas or from its imperfect combustion. It has been proved, however, that in the presence of the flame of illuminating gas the vapor of chloroform is broken up, not only into chlorine and hydrochloric acid, but also into an oxychloride of carbon, or phosgene (CO Cl_2), which is a violent poison, producing a sense of suffocation and inducing serious changes in the composition of the blood, with subsequent degeneration of various vital organs.

The last fatal occurrence attributable to the decomposition of chloroform by gas is reported from the clinic of Professor D'Urso, of the University of Messina. This led to experiments on animals by his assistant, Dr. G. Betagh, who has carefully investigated the whole question and reported the accident and the results of his experiments. It appears that, as the operating room was large and chilly, a gas stove had been installed to give the desired warmth, and been placed over nine feet away from the operating table. Two operations were performed. One was a laparotomy, and lasted no unusual time. The second was an operation for the radical cure of hernia. The first patient suffered after the operation with uncontrollable vomiting, headache, fainting attacks, and convulsions, and the urine was highly albuminous. She finally recovered, but at the time of the report still had a chronic nephritis.

The second patient died within twelve hours of the operation, with symptoms of internal hæmorrhage, and at the autopsy it was found that there was a great deal of free blood and clots in the abdominal cavity and in the layers of the wound, although there had been no slipping of ligatures; in fact no vessels of any magnitude had been severed, while the ligation of even the minute arteries had been careful and thorough.

The assistants, and especially the anæsthetizer, had suffered from headache, nausea, and vomiting. The chloroform was tested and found to be pure and in good condition. It was also shown that in the absence of chloroform vapor no ill effects were produced by the use of the stove. Experiments were made with a considerable number of rabbits and dogs, in which chloroform was administered while a small gas flame was placed near the head of the animal, and in all cases very serious symptoms developed, and if the narcosis lasted more than half an hour the animal died. On examination it was found that the proportion of hæmoglobin fell rapidly after the operation from 95 to 60 or in some cases as low as 40. There was suppression of urine, with convulsions and dyspnœa. After death sanguineous extravasations were found in the lungs and in the spleen. The kidneys were engorged, with hæmorrhagic extravasations. The canaliculi were often filled with red corpuscles and were in a condition varying from cloudy swelling to a loss of epithelium or even necrosis of their elements. In other experiments the gas flame was placed at a distance from the animal and the products of combustion were led by a tube under the chloroform mask, so that the animal received any carbonic oxide which might be formed, but the chloroform vapor was not in contact with the flame. These animals did not die or suffer any deleterious effects from this method of anæsthesia.

Among the cases recorded in literature, besides several where catarrhal pneumonia was observed, the most remarkable was that of Lorentz, who describes an operation for gunshot wound of the abdomen where chloroform was used in the presence of gas light. After the operation, which was a long one, two surgeons and four Sisters of Charity, who had assisted, were taken with symptoms of collapse, with cough and oppression, and one of

the Sisters died after twenty-eight hours. The patient died six hours after the operation, and the abdominal cavity was found to contain a large amount of blood. It is thus sufficiently proved that the utmost care must be used in administering chloroform in the presence of a gas flame, which in these days of gas stoves is a matter of the greatest importance. What the effect of other forms of flame may be does not appear from the literature, as all the cases of accident reported have been due to the use of chloroform in the presence of the flame of illuminating gas. Since, however, the injury is not caused by the products of the combustion of the gas, and since one flame is like another, it would appear that equal caution ought to be observed in using chloroform in the presence of any open fire, such as that of coal, for the flame of a coal fire is nothing but the flame of illuminating gas escaping from the hot coal.

Where accessory or occasional means of heating operating rooms are employed, the heater should be outside the operating room, and this can easily be arranged by means of some of the devices for heating water by means of gas, and thus transferring the heat to a radiator, which can be placed wherever desired. For artificial light electricity should always be preferred where it is obtainable, and if gas must be used it should be high above the field of operation, and if possible separated by some sort of skylight from the air of the operating room. Sterilizers which depend on gas flames should be kept in an adjoining apartment. Of course the use of ether, as is customary in many parts of this country, removes the dangers to which I have alluded, but with this agent there is always a danger of explosion in the presence of a flame, so that in any case anæsthetics and fire are to be kept as far as possible from each other. ERNEST W. CUSHING.

"ATROCIOUS ADULTERATION."

In the centenary number of the *Edinburgh Medical Journal*, which has been recently issued, the editors review its history in an article of considerable historical interest. From this we learn that adulteration of drugs was extensively practised in the first half of the nineteenth century. Sir Robert Christison, of *Dispensatory* fame, was one of the twelve past editors of the journal, and in a report which he made to the Royal College of Physicians, of Edinburgh, he stated that few medicines in gen-

eral use escaped occasional sophistication, the impurities being frequently so great as to render them therapeutically inefficacious. His attention was first called to the subject by failing in an experiment before his class to obtain the reaction for mercuric chloride with potassium iodide. On proceeding to inquire into the cause, he discovered that the iodide consisted of 80 per cent. of potassium carbonate, 10 per cent. of water, and only 10 per cent. of potassium iodide. "This atrocious adulteration," comment the editors, "was knowingly sold by a Glasgow firm all over Great Britain and accounted for the failures, often complained of at that time, in the use of the salt as a remedy in medical practice." Dr. Christison's report attracted widespread attention, and was responsible in no small degree for an improvement in the purity of drugs, which soon took place through legislative enactment and other means.

PREVENTIVE MEDICINE IN THE FIELD.

The military authorities of Japan have permitted but little information to reach the outside world concerning the details of the operations of their armies but such scant news as has been made public shows that she has gone further in the application of preventive medicine in the field than has any other power in the history of the world. We learn that sanitary authorities who accompanied or preceded the first line of advance examined the waters of the various wells, creeks, and rivers and labeled such waters as "potable," "non-potable," or "potable only after boiling" for the information of the troops who were to follow. This, coupled with a similar foresight in other directions, has reduced the sick list to a degree which seems almost incredible to those who are familiar with the history of our civil war and the Cuban campaign. We wonder if our own government will profit by this example? We hope for better things than our past experience would lead us to look for.

FOREIGN SUBSTANCES IN THE SUBWAY.

One effect of the recent sleety weather with its disagreeable consequences underfoot can hardly have been foreseen by those who anticipated an invariably clean and aseptic subway station. The adhesive compound of partially melted snow, tobacco quids, manure, cigar ashes, etc., deposited on the steps of the stations by the feet of passengers, form a feature scarcely less objectionable than the advertisements and slot machines which disfigure the subway not only in foul weather, but at all times. Would it not be feasible to have something resembling the old fashioned iron shoe scraper at the head of each subway staircase to remove at least the heavier particles of septic matter?

Society Meetings for the Coming Week:

MONDAY, February 13th.—New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medicohistorical Society (private; anniversary); New York Ophthalmological Society (private); Medical Association of the Greater City of New York; Society of Medical Jurisprudence, New York; Corning, N. Y., Medical Association; Gynecological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private).

TUESDAY, February 14th.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Society; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y.; Newark, N. J., Medical Association (private); Trenton, N. J., Medical Association; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Ky.; Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, February 15th.—Woman's Medical Association (New York Academy of Medicine); New York Society of Dermatology and Genitourinary Surgery (private); New York Academy of Medicine (Section in Genitourinary Diseases; Medicolegal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, February 16th.—New York Academy of Medicine; Brooklyn, N. Y., Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, February 17th.—New York Academy of Medicine (Section in Orthopaedic Surgery); New York East Side Physicians' Association; Manhattan Medical and Surgical Society (private); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending February 4, 1905:

	February 4.		January 28.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	185	8	174	7
Diphtheria and croup	311	49	272	40
Scarlet fever	233	15	248	13
Smallpox	1	1	8	..
Chickenpox	135	..	174	..
Tuberculosis	343	180	389	167
Typhoid fever	32	10	41	14
Cerebrospinal meningitis	33	33	..	28
	1,240	296	1,306	269

Sanitary Superintendent in Brooklyn.—Dr. Darlington has appointed Dr. Thomas Louis Fogarty to fill this office.

Reported Gift to Parisian Hospital.—It is stated that a wealthy citizen of New York has given \$200,000 to Professor Gauthier, of Paris, to add to one of the hospitals there a wing in which a radiant light bath may be established for the benefit of the poor who require treatment by such means.

Society of Sanitary and Moral Prophylaxis.—A meeting at the New York Academy of Medicine was held on Thursday, February 9th, at 8.30 p. m.,

for the purpose of discussing the advisability of forming in this city a Society of Sanitary and Moral Prophylaxis. A paper setting forth the object and aims of the proposed society was read by Dr. Prince A. Morrow. A discussion by Dr. Felix Adler, Professor E. R. Seligman, E. T. Devine, William A. Purrington, Dr. Stephen Smith, Dr. Keyes, Dr. Bangs, and others followed.

Accident to a New York Physician.—Dr. Jacob Glass, of 67 Second Avenue, and his driver, Bernard Simmons, were painfully cut and bruised on February 5th when a trolley car struck their buggy in front of the doctor's office. The carriage was overturned; Simmons falling on top of the doctor.

Diphtheria in Staten Island.—Dr. John T. Sprague, assistant sanitary superintendent of the Health Department in Richmond, ordered the closing of Public School No. 21, in Elm Park, on January 31st, because of the prevalence of diphtheria among the children. In the previous two weeks, forty-four cases of the disease had been reported to the Health Department. One third of the patients are pupils at the public school, which has an attendance of about six hundred and fifty children. So far no case has had a fatal termination. The school building has been thoroughly disinfected.

Eastern Medical Society.—The section on pædiatrics will meet on Thursday, February 16th, at 8.15 p. m., at Clinton Hall, 151 Clinton Street. Programme: Case of Aphemia Gradually Acquired One Year After an Attack of Cerebrospinal Meningitis, by M. Gertler, M. D.; Fusiform Bacilli (Vincent) and Spirilla from a Case of Ulceromembranous Angina, by Charles Herrman, M. D.; A Case of Hypertrophic Stenosis of the Pylorus, by F. L. Wachenheim, M. D.; Report of a Case of Tuberculous Meningitis Treated with Diphtheritic Antitoxine, by Cesare Mondini, M. D.; paper, Treatment of Eczema and Impetigo in Children, by Charles Warren Allen, M. D. Discussion opened by Boleslaw Lapowski, M. D., and Ludwig Weiss, M. D. Jacob Sobel, M. D., chairman; E. M. Sill, M. D., secretary, 222 West Fifty-ninth Street.

The Medical Association of the Greater City of New York.—A stated meeting of this association will be held at the New York Academy of Medicine on Wednesday, February 15, 1905, at 8.30 p. m. Attention is called to the change of the night of meeting the present month from Monday to Wednesday. The postponement was rendered necessary by the fact that Monday, February 13th, the regular date for the meeting, is this year a legal holiday. The meeting will be held in Du Bois Hall, on the second floor of the academy building. Order of exercises: Asepsis and Antiseptics in Obstetrics; Sterile Gauze and Sterile Water, by J. Milton Mabbott, M. D.; Perinæum, Perineorrhaphy, and Prolapse, by Arnold Sturm Dorf, M. D.; The Gynecologist and the General Surgeon—Their Respective Fields, by Brooks H. Wells, M. D. Discussion by Dr. Charles Jewett, Dr. C. A. Von Ramdohr, Dr.

Egbert H. Grandin, Dr. Robert L. Dickinson, Dr. H. J. Boldt, Dr. L. Grant Baldwin, Dr. S. Marx, Dr. E. E. Tull, Dr. George L. Brodhead, and Dr. H. N. Vineberg. Collation. J. Lee Morrill, M. D., treasurer; P. Brynberg Porter, M. D., recording secretary, 150 West Eighty-fourth Street.

New York County Medico-Pharmaceutical League.—At a stated meeting of the New York County Medico-Pharmaceutical League, held at the Hotel Astor on January 24th, the following resolutions were offered:

Whereas, In the demise of our late ex-president, Thomas H. Manley, M. D., the medical profession has lost an honored and a worthy member, who for many years contributed to medical science and surgical skill, and

Whereas, We realize that he might have given to this society the benefit of many years of valuable advice and unselfish personal service, it is with profound regret that we bow to the inscrutable will of Divine Providence; and therefore be it

Resolved, That in the loss of Thomas H. Manley, M. D., there has been taken from us a courteous gentleman, a benevolent and most useful citizen; and be it further

Resolved, That these resolutions be spread on the records of this society, and that they be published in the medical press, and a copy thereof be transmitted to the family of the deceased.

L. W. Zwisohn, M. D.,
Hermann J. Boldt, M. D.,
Samuel F. Brothers, M. D.,
Committee.

PHILADELPHIA.

Scientific Society Meetings for the Week Ending February 18, 1905.—Monday, February 13th, Section on General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. Tuesday, February 14th, Philadelphia Paediatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, February 15th, Section on Otology and Laryngology, College of Physicians; Association of Clinical Assistants of Wills Hospital. Thursday, February 16th, Section in Gynaecology, College of Physicians. Friday, February 17th University of Pennsylvania Medical Society; American Philosophical Society.

Appointments at the Jewish Hospital.—William B. Hackenburg, president of the Jewish Hospital Association, has made announcement of the following appointments on the hospital staff: Dr. Charles P. Noble, consulting surgeon; Dr. Lawrence F. Flick, consulting physician; Dr. William H. Randle, obstetrician; Dr. J. B. Potsdamer, paediatrist; and Dr. Sidney L. Feldstein, radiologist. Miss Margaret Pridham, who has been chief nurse and superintendent of the Medico-Chirurgical Hospital, and formerly of the Massachusetts General Hospital, of Boston, and of the Denver General Hospital, has been elected chief nurse and superintendent of the Nurses' Training School of the Jewish Hospital. She will assume her new duties on February 1st.

Ophthalmological Society Organized in Philadelphia.—Realizing the importance of a society in which clinical workers in ophthalmology may be able to report their interesting daily cases and enjoy full and free individual discussion upon the same, and present theoretical and statistical papers upon ophthalmic subjects, Dr. Oliver, of Philadelphia, has recently organized the Association of Clinical Assistants of Wills's Hospital. Membership by ballot is open to all those who have been or are connected with one or more of the clinical services in Wills's Hospital for a period of not less than three months' time. Meetings are held at the hospital at 8.30 p. m. on the first and third Wednesdays of each month. All who are eligible are invited to attend and join.

Statistics of Bureau of Health.—During December the Division of Medical Inspection of the Department of Public Health and Charities made 8,353 inspections of houses and business places and ordered 889 fumigations. Sixty-two cases were referred for special diagnosis. There were 5,030 visits to schools and 1,253 children were excluded from school. Two hundred and eighty-five cultures were taken; 86 injections of antitoxine made; and 2,370 vaccinations done. In the Division of Milk Inspection 163,977 quarts of milk were inspected; 1,981 quarts were condemned; 127 specimens were examined chemically, and 950 microscopically. In the Bacteriological Laboratory 1,340 examinations were made for diphtheria; 299 Widal examinations; 819 milk examinations; 102 examinations of sputum; and 1,990 bottles of antitoxine were supplied. In the chemical laboratory 210 analyses were made.

Meeting of the Trustees of the Presbyterian Hospital.—At a meeting of the trustees of the Presbyterian Hospital in Philadelphia, held January 17th, the following officers were elected:

President, the Reverend Dr. Charles A. Dickey; vice-president, Charles H. Matthews; treasurer, Frank K. Hippie; secretary, John H. Converse; trustees, the Reverend J. Hervey Beale, the Reverend Dr. Henry C. McCook, the Reverend Louis Benson, John H. Watt, the Reverend Charles Wadsworth, Jr., Henry B. Paul, Jr., John F. Craig, Dr. George W. Bailey, John B. Gest, and H. E. Prentiss Nichols.

The expenditures for the year exceeded the income by \$20,000. A movement to obtain \$50,000 more endowment has been started by the Ladies' Aid Society.

The Officers of the Pennsylvania Society to Protect Children from Cruelty for the ensuing year were elected on January 17th:

President, Charles C. Harrison; vice-presidents, Dr. Charles P. Turner, Thomas L. Gillespie, J. Percy Keating, Henry M. Dechert, G. Heide Norris, Mrs. E. H. Ogden, Mrs. George W. Ellis; treasurer, Joseph P. Mumford; board of managers (for three years), Dr. Charles P. Turner, Edward Coles, Henry M. Dechert, H. O. Hildebrand, Mrs. G. M. S. P. Jones, Mrs. H. W. Wilson, Mrs. George W. Ellis, Mrs. J. Willis Martin, Miss Caroline Mason, Edward B. Smith.

President Harrison's report showed that 314 of the 773 families referred to the society in the last seven months were placed under supervision. In addition 859 children were committed to the society's care in this period. The treasurer's re-

port shows a deficit of \$8,666 for the year in maintenance fund.

The Health of the City.—During the week ending January 28, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	82	11
Scarlet fever.....	65	2
Chickenpox.....	118	0
Diphtheria.....	62	10
Cerebrospinal meningitis.....	1	0
Measles.....	6	0
Whooping cough.....	16	0
Tuberculosis of the lungs.....	51	49
Pneumonia.....	63	67
Erysipelas.....	11	0
Puerperal fever.....	3	3
Anthrax.....	1	0

The total death rate for the week was 499, in an estimated population of 1,438,318, corresponding to an annual death rate of 18.04 per 1,000 population. The total infant mortality was 96; under one year, 78; between one and two years, 18. There were 33 still births; 17 males and 16 females. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 10; diarrhoea and enteritis, under two years, 14. During the week there were two snowstorms, lasting together nearly 48 hours. The temperatures fell steadily until the 26th, when a minimum of 6° was reached. The snowstorm of the 25th was accompanied by a high wind, which at one time recorded 40 miles per hour. The deaths from pneumonia and other respiratory diseases made a total of 101, or 20.24 per cent. of the total deaths.

The West Philadelphia Medical Association.—A new medical organization has been formed by physicians of West Philadelphia, and is known as the West Philadelphia Medical Association. Organized but a few months, it has already a membership of seventy-five. Its objects are to federate all reputable regular physicians in West Philadelphia, to encourage unity, promote harmony, to encourage a spirit of emulation in medical work and discussions, and to promote an active interest towards the members' material welfare. To the purely professional work which will be decidedly advantageous to medical men interested in the advancement of science, the organization has added social features which will ever keep alive the interest held in the association. At all meetings an hour is devoted to song, story, and music, and here also is given the opportunity of cementing and continuing friendship thus formed. The last meeting was held in Rittenhouse Hall, Fifty-third and Haverford Streets, at 9 p. m., on Friday, February 1st. The subject was Typhoid Fever, Its Pathology, Diagnosis, Complications, and Treatment. Discussion was opened on Pathology by Dr. F. Mortimer Cleveland, Diagnosis by Dr. J. E. Talley, Complications by Dr. J. H. McConnell, and Treatment by Dr. J. M. Eckfeldt. The present officers are:

President, Dr. A. F. Targette; vice-president, Dr. George C. Shammo; recording secretary, Dr. William D. Bacon; financial secretary, Dr. A. P. Good; treasurer, Dr. J. D. Brittingham; board of directors, Dr. J. W. McConnell, chairman; Dr. F. Mortimer Cleveland, secretary; Dr. E. L. Graf, Dr. Frank Kirby, Dr. S. F. Gilpin, Dr. F. R. Starkey, Dr. H. B. Smith, Dr. A. P. Good, Dr. Charles E. Price, Dr. B. F. Wentz, and Dr. J. D. Brittingham.

Members of the profession are cordially invited to any or all meetings, and will be royally welcomed.

GENERAL.

Cincinnati District Physician.—Dr. G. C. Alte-meier is to be appointed district physician in the twenty-second ward of Cincinnati, to succeed the late Dr. A. J. Hofling.

Scarlet Fever in Syracuse, N. Y.—It is stated that the health authorities of Syracuse are alarmed at the spread of scarlet fever in that town, 74 cases having been reported with 3 deaths.

Minnesota State Board of Medical Examiners.—At the request, it is said, of the Woman's Medical Club, of Minneapolis, Dr. Margaret Koch has been appointed a member of this body to succeed Dr. Adele Hutchinson.

The Quarter Century Medical Club, of Detroit, elected the following officers at its meeting on January 27th: President, Dr. Herman Kiefer; vice-president, Dr. J. E. Emerson; secretary, Dr. W. C. Stevens; treasurer, Dr. Eugene Smith.

Schenectady County Medical Society.—At a meeting of this society, held on January 10th, the following officers were elected: President, Dr. W. L. Fodder; vice-president, Dr. Louis Faust; secretary, Dr. F. C. Reed; treasurer, Dr. G. B. Johnson.

The Tioga County, N. Y., Medical Society has elected the following officers: President, Dr. H. I. Dunbar, of Candor; vice-president, Dr. A. W. Stiles, of Apalachin; secretary, Dr. Leon Detowski, of Waverly; treasurer, Dr. J. M. Barrett, of Owego.

Dr. Anita Newcomb McGee has been made a member of the United Spanish War Veterans, and is the only woman holding membership in that organization. Dr. McGee during the war with Spain was commissioned acting assistant surgeon.

The Milwaukee Medical Society has elected the following officers: President, Dr. H. B. Hitz; vice-presidents, Dr. William Thorndike and Dr. Oscar Chryslor; secretary, Dr. H. E. Dearholt; treasurer, Dr. R. C. Brown; librarian, Dr. A. W. Myers; curator, Dr. O. F. Fieter.

Albany Board of Health.—A competitive civil service examination for the position of sanitary inspector in the Albany board of health will be held in the common council chamber on Tuesday, February 21st, at 2 p. m. Applications must be filed with the secretary of the commission on or before Wednesday, February 15th, at 3 p. m.

Dr. E. C. W. O'Brien, surgeon of the Buffalo fire department, is critically ill at his home, No. 1195 Main Street. Dr. O'Brien suffered a severe attack of gripe about ten days ago and complications now have set in which make his physicians fear for his ultimate recovery. Dr. O'Brien has been the official surgeon of the fire department for many years. Dr. William G. Ring, of 364 Niagara Street, has been designated as physician to the fire department during the illness of Dr. E. C. W. O'Brien.

Ramsey County, Minn., Medical Society.—Dr. A. W. Dunning was elected president of the Ramsey County Medical Society, in annual session, on January 28th. Dr. Burnside Foster was elected vice-president; Dr. E. F. Geer, secretary; Dr. F. W. Leavitt, treasurer; and Dr. A. F. Whitman, necrologist.

Smallpox in Virginia.—Greensville County, Va., reports twenty-one cases of variola among colored people for January. The disease so far has proved very mild, barring three cases which may terminate fatally. The contagion was brought from Haverstraw, N. Y. L. Lafon, M. D., health officer.

Chenango County Medical Society.—At the hundredth annual meeting of this society, held on January 10th, the following officers were elected: President, Dr. L. C. Palmiter, of Mount Upton; vice-president, Dr. B. A. Harris, of Norwich; secretary, Dr. F. O. Spooner, of Sherburne; treasurer, Dr. S. M. Hand, of New Berlin.

Opening of a New Hospital in Pittsburgh.—The new municipal hospital building in the thirtieth ward, Pittsburgh, was thrown open on January 31st for the reception of patients by order of Director of Public Safety Harry Moore. It is intended for persons suffering from any contagious disease.

The Macomb County, Mich., Medical Association, at its meeting on January 26th, elected the following officers for the ensuing year: President, Dr. P. A. Knight, of Mt. Clemens; vice-president, Dr. Robert Greenshields, of Romeo; president and treasurer, Dr. A. J. Warren, of Mt. Clemens.

Memorial Tablet for the Kingston, N. Y., Hospital.—The members of the Board of Managers and the Medical Staff of the City of Kingston Hospital have procured a beautiful bronze tablet which is to be placed upon the wall of the front hall of the hospital in memory of Dr. Jacob Chambers, who was one of the original organizers of the institution and served both as manager and attending physician and surgeon for many years.

Medical Society of the State of New York.—The ninety-ninth annual meeting of the Medical Society of the State of New York was brought to a close on February 2nd with the election of the following officers, who will serve for the ensuing year: President, Dr. Joseph D. Bryant, of New York; vice-president, Dr. Herman R. Ainsworth, of Addison, N. Y.; secretary, Dr. Frederick C. Curtis, of Albany; treasurer, Dr. O. D. Ball, of Albany. Dr. Charles G. Stockton, of Buffalo, who was a candidate for president, withdrew in favor of Dr. Bryant; and the election of officers was unanimous.

Dr. Henry E. Woodbury, a well known Washington practitioner, died on January 15th. He was a graduate of Dartmouth College and Georgetown University Medical School. After serving as an acting assistant surgeon during the civil war, Dr. Woodbury located in Washington and practised there for 25 years, when an accident compelled him to relinquish his professional du-

ties. He was a contributor to many medical journals during his career. The doctor was a direct descendant of Captain Woodbury, who commanded a company in Colonel Stark's regiment at the battle of Bunker Hill.

International Society of Tuberculosis.—A new scientific society has just been founded in Paris, under the name of the *Société Internationale de la Tuberculose*. Its office is in Paris. Meetings are held monthly, on notice from the general secretary. The scope of this association is the study of all questions concerning tuberculosis and the centralization of means of defence. Its work will be published. The society is composed of medical men or savants holding diplomas from French or foreign universities and colleges. Admission may be obtained by application to the president, which application must be accepted by a committee elected at a general meeting. The annual subscription is 10 francs (\$2.50). For further particulars and for application forms, address M. le docteur Georges Petit, General Secretary, 51 rue du Rocher, Paris, France.

Emergency Hospital, Denver.—The stockholders and board of directors of the Denver Emergency Hospital held their annual meeting on January 25th, and, together with eleven of the most prominent physicians and surgeons of the city, merged themselves into the Emergency and General Hospital Association, with \$10,000 capitalization. Its ultimate purpose is the enlargement and improvement of the present institution and in the course of time the erection of a handsome new building. The officers of the association are: President, Dr. John D. Crisp; first vice-president, Dr. C. B. Richmond; second vice-president, Dr. D. R. Lucy; third vice-president, Dr. Bernard Oettinger; secretary, Dr. J. W. Austin; treasurer, Dr. S. Simons. Mrs. M. M. Day will remain matron and Miss Daisy Blackburn head nurse.

Memorial Gift to the Chicago Medical Society.—The memorial bust of Dr. Christian Fenger will be formally presented to the Chicago Medical Society soon by members of the organization. The bust is to be placed in the Cook County Hospital, where Dr. Fenger operated for twenty years. Dr. Ludwig Hektoen is chairman of the committee on arrangements. He states that there will be enough money left after paying the \$3,000 for the bust to establish a Christian Fenger membership in one of the local medical colleges. It has not been decided which school is to be the recipient, as Dr. Fenger served on the faculty of three. Dr. Fenger was born in Copenhagen, Denmark, and held the chair of pathology in the Danish University of that city. Since coming to Chicago he had at different times held the chair of surgery in the Physicians and Surgeons College, the Northwestern Medical College, and Rush College. He was pathologist on the staff of the Cook County Hospital for fifteen years. At the time of his death he was president of the Chicago Medical Society.

Statement of Mortality in Chicago for the Week Ending February 4, 1905, compared with

the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905, and of 1,932,315 for 1904:

	Feb. 4, 1905.	Jan. 28, 1905.	Feb. 6, 1904
Total deaths, all causes.....	530	558	596
Annual death rate per 1,000...13.88		14.61	16.11
By sexes—			
Males.....	297	312	338
Females.....	233	246	258
By ages—			
Under 1 year.....	114	118	116
Between 1 and 5 years.....	58	45	46
Over 10 years.....	104	115	120
Important causes of death—			
Acute intestinal diseases.....	23	16	13
Apoplexy.....	16	12	14
Bright's disease.....	30	44	48
Rheumatism.....	28	15	31

All other causes.....	85	141	101

Medical Society of the Missouri Valley.—The seventeenth semiannual meeting of this association will be held in Kansas City, March 23rd and 24th. An excellent programme is being arranged for the occasion, and the local medical profession, which is noted for its hospitality, will keep open house for the visitors upon this occasion. Dr. S. Grover Burnett, of Kansas City, is president of the society, and Dr. C. Lester Hall, chairman of the arrangement committee. Following is a list of the papers which have already been given a place upon the programme:

Paper, by George W. Cale, M. D., of Springfield, Mo.; Surgical vs. X Ray Treatment in Cases of Rodent Ulcer and Epitheliomata of the Face, with Demonstration of Cases Operated Upon, by C. O. Thienhaus, M. D., of Milwaukee, Wis.; Transverse Ribbon Shaped Corneal Opacity, by J. M. Sherer, M. D., of Kansas City, Mo.; Rest in the Treatment of Select Cases of Mental Disease, by F. E. Norbury, M. D., of Jacksonville, Ill.; paper, by E. N. Wright, M. D., of Olney, I. T.; Surgery of the Spine, by C. E. Black, M. D., of Jacksonville, Ill.; Synchronous Extra and Intrauterine Pregnancy, with Report of Case, by D. C. Brockman, M. D., of Ottumwa, Ia.; Remarks on the Surgery of Umbilical, Femoral, and Inguinal Hernia, with Reported Cases, by J. Young Brown, M. D., of St. Louis; Case of Chorioiditis, Probably Due to Necrosing Eithmoiditis, by W. W. Bulette, M. D., of Pueblo, Colo.; Pelvic Inflammation, or Peri and Parametritis, by H. C. Crowell, M. D., of Kansas City, Mo.; Renal Affections Simulating Abdominal and Pelvic Diseases, by J. Block, M. D., of Kansas City, Mo.; The Newly Born Infant; Its Care and Management, by A. D. Wilkinson, M. D., of Lincoln, Neb.; Anesthetics, by Dora Greene-Wilson, M. D., of Kansas City, Mo.; Some Observations Upon the Treatment of Inguinal Hernia, by Prince E. Sawyer, M. D., of Sioux City, Ia.; Functional Diagnosis of Kidney Diseases, by A. C. Stokes, M. D., of Omaha, Neb.; Hypertrophy of the Thyroid Gland, by T. E. Potter, M. D., of St. Joseph, Mo. A feature of the programme will be a "symposium" on Puerperal Fever, opened by Robert T. Sloan, M. D., of Kansas City. A cordial invitation is extended to the medical profession and special rates will be granted by the railroads. Further information and copy of the complete programme, which will be issued March 10th, may be obtained by addressing the secretary, Charles Wood Fassett, M. D., of St. Joseph, Mo.

Health in Michigan During January, 1905.—Reports to the State Board of Health, by repre-

sentative physicians in active general practice, in different parts of the State, show the diseases which caused the most sickness in Michigan during the month of January (four weeks ending January 28th), 1905, to be as follows:

	Number of reports received for this month.....	279
	Per cent. of reports stating presence of disease.	
	Average for	
	January, 10 years, all months,	
	1904, 1895-1904, 1895-1904.	
Diseases arranged in order of greatest prevalence in this month.	1905.	
Rheumatism.....	63	62
Influenza.....	55	49
Bronchitis.....	54	56
Nervous.....	53	56
Amalgamitis.....	52	51
Gonorrhea.....	50	55
Syphilis.....	33	*
Diarrhea.....	23	21
Consumption, pulmonary.....	23	23
Cancer.....	18	19
Pleuritis.....	17	12
Inflammation of kidney.....	16	20
Smallpox.....	12	11
Typhoid fever—Enteric.....	10	12
Typhomalarial.....	2	3
Scarlet fever.....	11	12
Measles.....	8	8
Pneumonia.....	10	10
Inflammation of bowels.....	7	9
Intermittent fever.....	6	11
Erysipelas.....	5	5
Diphtheria.....	4	6
Cholera morbus.....	3	1
Inflammation of brain.....	2	2
Whooping cough.....	1	6
Puerperal fever.....	1	2
Remittent fever.....	1	2
Dysentery.....	1	4
Cholera infantum.....	1	0.7
Meningitis.....	0.7	0.7
Membranous croup.....	0.7	0.4

At the State Capitol for the month of January, 1905, compared with the average for January in the ten years, 1895-1904, bi-daily observations show the prevailing direction of the wind to have been the same (southwest), the velocity .2 of a mile an hour less, the average temperature 4.43 degrees lower, the average daily range of temperature .51 of a degree less, the average daily range of atmospheric pressure .059 of an inch less, the precipitation .17 of an inch less, the absolute humidity less, the relative humidity more, the day and night ozone much less, and the depth of water in the observation well 6 inches less. For the month of January, 1905, compared with the average for January in the ten years 1895-1904, smallpox, measles, and cholera morbus were more than usually prevalent; and scarlet fever, pneumonia, intermittent fever, erysipelas, diphtheria, whooping cough, puerperal fever, remittent fever, and dysentery were less than usually prevalent.

THE MOST DANGEROUS COMMUNICABLE DISEASES.

Including reports by regular observers and others, whooping cough was reported present in Michigan during the month of January, 1905, at 10 places; meningitis, at 15 places; measles, at 63 places; diphtheria, at 83 places; scarlet fever, at 109 places; pneumonia, at 101 places; smallpox, at 104 places; typhoid fever, at 108 places; and consumption, at 267 places. Reports from all sources show whooping cough reported present at 9 places less; meningitis, at 10 places more; measles, at 12 places more; diphtheria, at 8 places less; scarlet fever, at 17 places less; pneumonia, at 19 places more; smallpox, at 3 places more; typhoid fever, at 3 places more; and consumption, at 26 places more, in the month of January, 1905, than in the preceding month. Henry B. Baker, secretary.

Pith of Current Literature

PRESSE MEDICALE.

December 31, 1904.

1. Clinical Examination of the Back of a Child,
By R. DESFOSSES.
2. The French Mediterranean Climate from a Clinical
Point of View. Climatic Diagnosis and Prognosis.
Climatic Test, By GASTON SARDOU.
3. The Œsophagolacrimal Reflex, By H. DELAUNAY.

1. **Examination of the Back of a Child.**—Desfosses describes the various forms of disease of the vertebræ met with in children, and supplements his description by twenty-two very serviceable illustrations.

2. **The Climate of the French Mediterranean.**—Sardou declares the action of this climate to be tonic, excitant, or sedative according to the distance from the water and other topographical circumstances on the one hand and the nature of the disease, or of certain of its forms, from which the patient is suffering.

3. **The Œsophagolacrimal Reflex.**—Delaunay does not agree with Carnot that it is difficult to discern any useful physiological purpose for this reflex. He presents what he holds to be an explanation, but it is not clear and does not seem to demonstrate what useful purpose is subserved thereby.

January 4, 1905.

1. Galloping Typhoid Fever,
By H. ROGER and M. SALOMON.
2. Pathogenesis and Treatment of Chronic Articular Rheumatism,
By C. PARHON and J. PAPINIAN.

1. **Galloping Typhoid Fever.**—Roger and Salomon give a detailed history of a case of typhoid fever which terminated fatally on the eighth day.

2. **Chronic Articular Rheumatism.**—Parhon and Papinian are inclined to ascribe this disease to modifications of the functions of certain internal glands, particularly the ovary and the thyroid body.

January 7, 1905.

Neurofibrillæ According to the Method of S. Ramon y Cajal,
By L. AZOULAY.

Neurofibrillæ.—Azoulay presents a well illustrated article on the presence of nerve fibrils in the neurones of invertebrates.

LYON MEDICAL.

December 25, 1904.

1. Two New Instruments: a, Hemostatic Scissors for Cutting Tissues. b, Angiotribe for Reducing the Pedicle,
By M. R. CONDAMIN.
2. Cæsarean Operation Performed Before Labor. Great Deformity of the Foetal Head, By M. PLANCHU.

1. **New Instruments.**—Condamin presents a scissors which compresses the tissues on each side of the incision, thus preventing hæmorrhage; also an angiotribe intended to be used when it is de-

sired to maintain pressure for some time without using the hand.

2. **Cæsarean Operation.**—Planchu operated prior to the onset of labor on a rachitic patient and removed a child which presented very marked deformities of the head.

January 8, 1905.

1. New Apparatus for Exploratory Puncture Adapted to Potain's Aspirator, By M. V. THEVENET.
2. Two Cases of Painful Accommodation,
By M. G. CORONAT.

1. **Apparatus for Exploratory Puncture.**—Thevenet employs a glass syringe body with the needle attached to one end, while the other is connected with the aspirator by means of a flexible tube.

2. **Painful Accommodation.**—Coronat describes two cases of accommodative asthenopia in moderately young people who had only .25 and .50 of a dioptrie of hypermetropia each.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

December 4, 1904.

(The following abstract was misplaced through an oversight; it should have been published in our issue of February 4th.)

1. The Pyloric "Bosse," By STEFANO MIRCOLL.
2. A Case of Acromegaly Studied from the Viewpoint of the Blood, By CARLO CAVALIERI DUCATI.
3. Action of Antimony on the Blood,
By S. MONTENAGNO.
4. The Therapeutic Uses of Veronal, By A. CAVAZZANI.
5. Critical Notes on Fiorani's Method in the Treatment of Angeliomas,
By FERRUCCIO BINDI.
6. Contribution to Scclavo's Antianthrax Treatment,
By FORTUNATO CORSINI.

1. **The Pyloric Bosse.**—Mircoli contends that the four distinct portions of the gastric apparatus of the ruminants are represented in man by four parts of the stomach, namely, the fundus, the body of the stomach, the antrum, and the pylorus. The pyloric antrum in man, he thinks, has retained some of the characters of an independent organ. Thus, comparative physiology teaches that the antrum is rather a motor organ than a digestive one, and that the body of the stomach is more prominently the seat of the digestive functions. While the secretion of the body of the stomach is acid, that of the antrum is alkaline. During the process of digestion, the antrum, by its systole and diastole, pumps the chyme from the body of the stomach into the pyloric orifice. It is therefore the power of the antrum to regulate the passage of the chyme from the stomach. The alkaline elements in its secretion neutralize the acid chyme, and thus enable the pyloric orifice to open. The closure of the pyloric valve, as we know, is effected through what is known as Meiring's reflex, that is, in virtue of the acidity of the gastric contents the fibres of the pyloric valve contract, thus preventing a too rapid influx of acid into the intestine. When this acidity is partly neutralized the stimulus is weakened, and the

valve opens. Inasmuch as alkalies tend to open the valve, their importance in diseases of gastric motility will be readily understood. In a variety of affections of the stomach this differentiation into different parts is marked by the appearance of "bosses," on the stomach walls, which show the antrum, etc. A prominence may exist in the epigastrium corresponding to the antrum of the pylorus, and at times this is accompanied by dilatation of the stomach as a whole. In partial gastrectasias the most prominent manifestation may be a pyloric boss which is probably produced by contractions of the sphincteric fibres in front and behind the pylorus, together with atony of the latter. The chief symptoms in such cases are of a neurosthenic character. The treatment consists of appropriate diet, of the use of an abdominal bandage, the administration of sodium sulphate, and of small doses of *nux vomica*.

2. Action of Antimony on the Blood.—Montenagno found that antimony is an excellent hæmatinic. It increases the number of red blood cells, and the percentage of hæmoglobin, and also enhances the resistance of the red cells, just like arsenic. The improvement in the blood which is produced after taking antimony persists from some time after the drug has been discontinued. Large doses of antimony, however, produce hæmolytic.

5. Criticism of Fiorani's Method of Removing Nævi.—Bindi finds that Fiorani's method of removing nævi has certain inconveniences and disadvantages, but on the whole it is easily applied and very efficient. The chief objection to it is that when, as often happens, the nævus is close to the eye, an intense congestion of the conjunctiva, with photophobia, lacrymation, œdema of the lids, etc., is apt to occur. The method in question consists in the application of corrosive sublimate dissolved in collodion (flexible). Several applications may be required. The corrosive sublimate acts as a caustic. A 13 per cent. solution is recommended. Dressings are unnecessary and the nævus may be allowed to atrophy undisturbed after the desired caustic action has been produced.

RIFORMA MEDICA.

December 21, 1904.

1. On the Syndrome Known as Polyglobulia with Tumor of the Spleen and Cyanosis, By MAURIZIO ASCOLI.
2. Sugar in the Treatment of Pulmonary Phthisis, By R. MASSALONGO and G. DANIO.
3. Contribution to Our Knowledge of the Physiopathology of the Pancreatic Cell (*Concluded*), By ETORE SAVAGNONE.
4. Contribution to the Anatomical and Experimental Study of Free Bodies in the Large Serous Cavities (*Concluded*), By LUIGI TOMELLINI.

1. Polyglobulia.—Ascoli writes on the syndrome described for the first time by Vaquez a few years ago, known as polyglobulia with swelling of the spleen and cyanosis. Since then a number of cases of this type have been reported in various countries, aggregating at present thirty clinical histories. The central symptom of these cases was a very marked increase in the red blood

corpuscles which reached, in one case reported by Cabot, the number of twelve millions to the cubic millimetre. Even with the naked eye the abnormal density of the blood could be detected. The morphology of the red cells, their relative number as compared with the white cells, the amount of hæmoglobin, and the specific gravity of the blood were also altered in these cases. The blood showed occasional nucleated red cells, and poikilocytes, but the average size of the red blood cells remained normal. There was often a polymorphonuclear leucocytosis, also not infrequently mastcells and eosinophiles in increased numbers. The hæmoglobin was usually greater than normal, but there are some exceptions on record. The specific gravity was increased up to 1.080. The spleen was enlarged and reached at times the crest of the ilium. It was hard and smooth on palpation. The third leading symptom was a cyanosis accompanied sometimes by the appearance of pigmented plaques and bronze discolorations. There are other minor symptoms of a vasomotor character, the patients look plethoric, and suffer from thirst; they have slight albuminurias, headaches, vertigo, etc., but in some cases all subjective symptoms are absent. The disease is a chronic one and lasts for years. In some cases that came to an autopsy tuberculosis of the spleen (primary) was found. The disease is assumed to be due to an abnormally increased function of the bone marrow. The author reports a case of this kind, leading features of which corresponded with the description just given. The treatment is symptomatic. The patients obtain transient relief from small bloodlettings. The diet should be deficient in iron. Arsenic has been given with some success and the Röntgen rays have been used with results analogous to those obtained in leucemia. In severe cases, especially where tuberculosis of the spleen is probably present, splenectomy may be thought of.

2. Sugar in Tuberculosis.—Massalongo and Danio, of Verona, discuss the subject of overfeeding in tuberculosis, as practised in hospitals. A method which has given results far beyond expectation, is the overfeeding of patients with sugar. Ordinary sugar is not only a promoter of heat, but also a dynamogenous food which is well adapted to the requirements of the cachectic consumptive. The authors recommend large doses, from 100 to 500 grammes of sugar daily; in other words, from 5 to 12 grammes of sugar per kilo of body weight. The patients gain weight rapidly, in some cases faster than the actual weight of the sugar ingested would warrant. They never suffer from fermentation or other gastric complications. Sugar gives the best results in the febrile cases. It may be diluted with milk or disguised with coffee or bitter tinctures. Sugar diet is well borne by those tuberculous patients who are otherwise difficult to feed, and even by those who cannot take cod liver oil.

4. Free Bodies in the Serous Cavities.—Tomellini's conclusions from a detailed study of the portions of tissue which may become free and float in the serous cavities are as follows: Free

bodies may develop in the pericardium, as the result of the detachment of a fatty lobulated mass from the serous membrane. Larger bodies may float free in the peritonæum, as the result of the detachment of an epiploic appendage. Repeated torsions of these appendages may finally result in their detachment from the intestine. A free body of this kind may be produced experimentally by tying off one of the epiploic processes at its junction with the serous membrane. Influences which produce slow irritation in the free bodies in question may give rise to an increase in connective tissue within them, and thus effectually oppose their more or less rapid absorption.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

February 4, 1905.

1. Conservative Perineal Prostatectomy. A Report of Fifty Cases, By HUGH H. YOUNG.
2. The Operative Treatment of Chronic Suppuration of the Frontal Sinus, with Special Reference to the Method of Killian, By A. LOGAN TURNER.
3. Dementia Præcox, By F. X. DERCUM.
4. The Nature of Traumatic Sclerosis, By ARTHUR CONKLIN BRUSH.
5. Prevalence and Prophylaxis of Pneumonia, By EDWARD F. WELLS.
6. The Relation of Internal Secretion to Epilepsy, Puerperal Eclampsia, and Kindred Disorders, By CHARLES E. DE M. SAJOURS.
7. The Axis of Astigmatism, By J. HERBERT CLAIBORNE.
8. The Relation of Corneal Curvatures to the Refraction of the Eye, By MELVILLE BLACK.
9. The Mechanical Treatment of Hip Disease, By ADOLPH LORENZ.
10. The Management of Prison Tuberculosis, with the Aid of Tuberculin as a Diagnostic Agent, By JEWETT B. REED.
11. Amygdalectomy, Thorough, Painless, and Safe, By E. FLETCHER INGALS.
12. Immunity. Chapter II.—Infectious Ætiology.

1. **Perineal Prostatectomy.**—Young, in a paper published one year ago, described a new method of performing perineal prostatectomy. A number of special instruments are required for operating by the method then advocated. The object of the present paper is to outline the results obtained in fifty cases by this new operation. The prostate by means of a tractor is brought well into the perineal wound, its capsule opened on either side of the median line, and the gland enucleated. It is possible to save from injury, in the majority of cases, the urethra and the ejaculatory ducts. The author thinks highly of this plan of treatment.

3. **Dementia Præcox.**—See this *Journal*, Vol. LXXX, page 89.

4. **Traumatic Sclerosis.**—See this *Journal*, Vol. LXXX, page 89.

9. **Hip Disease.**—Lorenz discusses his method of treating tuberculous hip disease which has not reached the suppurative stage. He is opposed to the ordinary treatment in vogue in America which consists of confinement to bed with extension to the diseased leg. His method is an ambulatory one. During the first months the

hip and thigh are put up in plaster. When the pain demands it a steel brace is added to the plaster dressing. During the whole course of treatment the patient is allowed to use the diseased leg. The author claims better end results by this plan of treatment than can be obtained by any of the methods based on placing the leg on the diseased side at absolute rest.

11. **Amygdalectomy.**—Ingals advocates the use of the cold wire snare in performing amygdalectomy. He describes and illustrates a number of instruments which he has devised in order to facilitate the mechanical difficulties of the operation.

BOSTON MEDICAL AND SURGICAL JOURNAL.

February 2, 1905.

1. The Relation of the Epileptic to the Community, By WILLIAM N. BULLARD.
 2. The State's Relation to the Epileptic, By OWEN COPP.
 3. The Tuberculosis Problem, and Some Suggestions in Dealing with It, By EDWARD O. OTIS.
 4. The Treatment of Hæmorrhoids by the General Practitioner, By T. CHITTENDEN HILL.
 5. Consumption and Its Borderland. Public and Professional Concern, By PAUL PAQUIN.
2. **Epilepsy.**—Copp asserts that there are about 120,000 epileptics in the United States. It should be the duty of the State to provide for these unfortunates: (1) Because, generally speaking, they are a menace to the peace of the State. (2) Because they have the same rights as other citizens, and should be provided with proper education and protection. (3) Because it is probably cheaper in the end to provide for the mentally deficient than to meet the indirect loss due to their crimes and misbehavior. (4) Because the families to which they belong are not capable of taking proper care of them. The author indicates, in a very general way, how the State should provide for its epileptics.

3. **Tuberculosis.**—Otis summarizes his ideas concerning the tuberculosis problem thus: "We must continually insist upon the danger of tuberculous sputum, and hence the positive danger, always present, of promiscuous spitting; and, secondly, insist upon the importance of wholesome living—fresh air, good food, rest, and cleanliness. We shall never stamp out consumption by directing our efforts solely against the source of infection. We must also labor to promote conditions of wholesome living; teach the people the elements of personal and house hygiene; teach them what is and how to obtain this wholesome living. On these two lines of effort must we depend in our exertions to stamp out the disease."

4. **Hæmorrhoids.**—Hill divides piles into external and internal. The external are of two kinds: (a) the thrombotic, which are best treated by incision and packing, and (b) the connective tissue hæmorrhoids, which should be excised with curved scissors. The wound if necessary may be stitched with catgut. Internal piles are best treated by ligation. This is easy with the protruding variety. The injection method is useful at times. All these operations may be done

painlessly under local anæsthesia. The author gives quite minute directions concerning the technics he recommends, so that his advice may be easily followed.

MEDICAL NEWS.

February 4, 1905.

1. Presidential Address, By CHARLES L. DANA.
2. Partially Afebrile *Æstivoautumnal* Malarial Infection Having Its Origin in New York City, By J. L. POMEROY.
3. Summer Infant Mortality, By LOUIS C. AGER.
4. Serum Diagnosis of Typhoid Fever by Means of Ficker's Typhus-Diagnosticum, By JOHANNES H. M. A. VON TILING.
5. Inflammatory Stricture of the Rectum, By J. M. FRANKENBURGER.
6. A Case of So Called Traumatic Asphyxia, By RANDOLPH WINSLOW.

2. *Æstivoautumnal* Malaria.—Pomeroy reports a case of *æstivoautumnal* malaria that was treated at the Charity Hospital. The points of interest in this case are: (1) An *æstivoautumnal* infection having its origin in New York city. (2) Chills and sweats without temperature—the latter appearing only when quinine had been administered, and then not rising above 100.2° F.

3. Summer Infant Mortality.—Ager's paper is necessarily statistical. He shows that infant mortality in New York city steadily declined between 1881 and 1898. Since 1898 the improvement has been slight if any. The paper emphasizes one fact chiefly: It is that the infant mortality in Brooklyn is considerably higher than in Manhattan. The author is of opinion that this is due to the better education of the profession and of the public in Manhattan. Across the river modified milk is the exception and condensed milk the rule in infant feeding.

4. Serum Diagnosis in Typhoid.—Von Tiling calls attention to the utility of the method of making a serum diagnosis of typhoid fever by means of bouillon cultures of typhoid bacilli in which the bacilli have been killed. Such cultures are now on the market. As is well known the Widal reaction consists in the clumping of live bacilli by the serum of a typhoid patient. In Ficker's reaction dead bacilli are clumped. Method: Three small test tubes are filled with a fixed quantity of bouillon culture. To the first nothing is added; to the second a certain quantity of diluted blood serum; to the third dilute blood serum one half the strength of that used in tube two. If cloudiness appears in tubes two and three and precipitation takes place the reaction is positive. Tube one is the control tube. Graduated tubes and full directions are furnished with the serum. The cost of each test is about two dollars.

6. Traumatic Asphyxia.—Winslow reports one case of so called traumatic asphyxia. The condition is rare. It is characterized by a blue discoloration of the face and part of the neck following, usually, compression of the chest. The phenomenon is due, not to hæmorrhage, but to an overdistention of the capillaries.

MEDICAL RECORD.

February 4, 1905.

1. Sanitary Conditions as Encountered in Cuba and Panama, and What is Being Done to Render the Canal Zone Healthy, By WILLIAM C. GORGAS.
2. Intramuscular Hæmorrhage from Muscular Action, By ANDREW H. SMITH.
3. A Review of Some Recent Papers on the Surgical Treatment of Prostatic Hypertrophy, By E. G. BALLENGER.
4. The Diagnosis of Renal and Ureteral Calculi, By H. A. FOWLER.
5. Growth of Bone in the Tonsil, By WILLIAM WESLEY CARTER.
6. Report of Three Cases of Intestinal Anastomosis by the Connell Suture, By H. H. SINCLAIR.

1. **Cuba and Panama.**—Gorgas first details the various measures which finally proved successful in bettering the sanitary condition of Cuba. In the effort that is being made to improve the conditions of the canal zone, the experience gained in Cuba will be invaluable. The problem at Panama is, however, an exceedingly difficult one. Yellow fever can without much doubt be easily controlled. The disease to be dreaded most is malaria. This, the notorious Chagres fever, is the *æstivoautumnal* type of the disease. There are along the canal zone some twelve thousand natives, most of whom harbor the parasite. Mosquitoes are more than abundant. The general sanitary plan contemplates first the extermination of the mosquito and second the extermination of the malarial parasite in the blood of the natives by means of quinine.

2. **Intramuscular Hæmorrhage.**—Smith asserts that a sharp distinction must be made between those cases in which hæmorrhage occurs within an unruptured muscular sheath and those cases in which the sheath is torn and the blood can escape into the surrounding tissues. When the sheath is not ruptured pain and disability will be extreme and complete cure may not occur for months. In the second type of cases recovery will usually take place in a few weeks.

3. **Prostatic Hypertrophy.**—Ballenger concludes: (1) Literature on prostatic surgery has been very confusing, owing to the large number of methods of operation advocated by prominent surgeons. (2) Suprapubic drainage of the bladder is advised in those cases too weak to withstand an operation; if improvement follows this procedure, then a radical operation is indicated. (3) There are three radical methods that are without doubt the most valuable; suprapubic prostatectomy, perineal prostatectomy, and the Bottini operation, and each of these has a definite place in prostatic surgery. (4) The relative advantages and dangers of each method should be well known, as the pathology and conditions are so varied that no routine treatment for all cases can be advisable. (5) All patients should be operated on before the breakdown in catheter life, and the earlier the operation the fewer will be the complications encountered. (6) The suprapubic route is indicated when there is a

large intravesicular, mobile, adenomatous growth, with general health and bladder and kidneys in a satisfactory condition. (7) The perineal operation is more desirable for small, dense, fibrous prostates firmly attached, and those where the growth is largely along the urethra or back toward the rectum. (8) The Botini is indicated in those cases where prostatectomy is refused and in selected cases, where the general health and kidneys contraindicate more radical measures. Of course, it is never to be used for a large, rapidly growing hypertrophy. (9) In the suprapubic operations avoid hæmorrhage by keeping carefully between the capsule and the sheath. In the perineal operations carefully cut the central tendon of the perinæum close to the rectum, but with the finger in it to prevent injury. Avoid laceration of membranous urethra, as incontinence of urine will follow. (10) Marked improvement results in the large majority of cases where the operation has been properly selected and carefully performed.

4. **Calculi.**—Fowler asserts that the diagnosis of renal and ureteral calculi should be based on the following methods of investigations: (1) History of the case; (2) physical examination; (3) examination of the urine; (4) cystoscopy; (5) catheterization of the ureters; (6) radiography, and finally (7) exploratory incision. Each one of these points is discussed. An early diagnosis is important for the following reasons: (1) By early surgical interference, we can save the kidney and give the patient relief from a disease which, "though swift and fatal in anuria, torturing in colic, and slowly, grimly progressive in suppuration, also presents possible vistas of years of comparative health and comfort, a delusive prospect with which the timorous sufferer would fain brace his refusal of the knife." (2) The operation of nephrolithotomy offers a perfect cure. No operation in surgery is attended with more brilliant success. The mortality of this operation is about the same as that of lithotripsy, while the dangers of nephrotomy and nephrectomy are many times greater. (3) By an early diagnosis and operation, we avoid alarming and distressing complications and a final resort to these more serious operations.

AMERICAN MEDICINE.

February 4, 1905.

1. The History and Development of Surgery During the Past Century (*To be continued*),
By FREDERIC S. DENNIS.
2. Some Further Experiments Upon Rectal Alimentation,
By DAVID L. EDSALL and CASPAR W. MILLER.
3. The Diagnosis of Tuberculous Cavities in the Lung,
By HERMAN B. ALLYN.
4. Diet After the Age of One Year,
By J. P. CROZER GRIFFITH.
5. Acute Postoperative Thyreoidism: Report of a Case Recovery,
By S. EDWARD SANDERSON.
6. Fibrolipomatous Tumor of the Pharynx and Larynx,
By E. FLETCHER INGALS.

2. **Nutrient Enemas.**—Edsall and Miller record a number of experiments upon dogs conducted for the purpose of shedding light on the

value of nutrient enemas. Apparently, at present, the chief functions served by such injections are: First and most important, to provide fluids and various inorganic salts for the tissues. 2. To provide perhaps a third to a sixth of the requisite amount of food. 3. To prevent the anxiety of friends and patient that would be produced by giving no food. The experiments conducted were along two lines: (1) The authors attempted to give fats in the form of soap and determine to what extent it was absorbed by the large bowel. (2) They attempted to produce a good emulsion of fat that would remain emulsified after its introduction into the bowel and determine the extent to which it was absorbed. Neither set of experiments gave very encouraging results.

3. **Tuberculous Cavities.**—Allyn reviews in detail the various signs and symptoms which justify a diagnosis of tuberculous cavity in a lung. To sum up, our most trustworthy signs of tuberculous cavity in the lung are to be found in deficient expansion and flattening of the chest wall over the cavity; in a percussion note which is often a high pitched tympany, especially if percussion is made with the mouth open, but which may be only a muffled sound, or a dull or flat sound; in pectoriloquy (so called), particularly whispering pectoriloquy; in breath sounds which are cavernous, tubulocavernous, tubuloamphoric, or amphoric; and in a multiplicity of râles, chiefly moist râles, which after coughing may have resonating quality.

4. **Children's Diet.**—Griffith gives diet lists showing what a child should and should not eat between one year and four years of age. His advice does not differ from that found in the standard text-books, except possibly in one particular. After the second year he thinks that a child may with advantage have meat twice a day, that is, at breakfast as well as at dinner.

5. **Thyreoidism.**—Sanderson reports a case of acute thyreoidism which occurred after an abdominal section. The patient survived. The author believes that the administration of *Cactus grandiflorus* favorably influenced the thyreoidism.

MEDICINE

January, 1905.

1. Remarks Upon a Case of Severe Appendicitis Ending in Recovery Without Operation,
By ALLYN.
2. Air, Food, and Exercise in the Prevention of Tuberculosis,
By YBARRA.
3. The Rationale of Intestinal Antisepsis,
By HOLLEN.
4. Skiagraph of an Old Ununited Fracture of the Scaphoid Bone, Illustrating the Value of the X Ray in the Diagnosis of Such Fractures,
By HAMMOND.
5. Report of Three Cases of Acute Hæmatemesis,
By CONNELL.
6. The Modern Treatment of Specific Urethritis,
By CHRISTIAN.
7. Lecture on Tropical Medicine,
By GRAFF.

2. **Air, Food, and Exercise in the Prevention of Tuberculosis.**—Ybarra quotes Koch, who insists upon the importance of the prevention of tuberculosis and of teaching the public how to avoid the disease. He affirms that pulmonary

tuberculosis is invariably a disease which is related to a disturbance of the digestive function. One who habitually lives under debilitating conditions as regards air, food, and bodily exercise is liable to be attacked at any period of his life by this disease, though there may not be in his constitution the slightest trace of hereditary tendency thereto. The two objects to be held constantly in view in the prevention of this disease are: 1. To cultivate invulnerability of the organism. 2. To destroy or suppress the bacillus. For the first of these there must be plenty of pure air, sunlight, nutritious food, physical exercise, proper clothing, hygienic surroundings, and a steady, methodical, moral life. For the second, there must be abundance of fresh, pure air, super-alimentation, gradually increased bodily exercise, recreation, and everything that makes life agreeable.

3. The Rationale of Intestinal Antisepsis.—Hollen observes that, in general, intestinal antiseptics are indicated whenever there are local fermentation and putrefaction. These may be manifested by discolored and fetid discharges, pain and tenderness in the abdominal region, diarrhoea, vomiting, foul breath, irregular heart action, fever, enlarged spleen, and other evidences of autointoxication. Such symptoms are present in typhoid fever, gastroenteritis, cholera infantum, acute and chronic diarrhoea, amœbic dysentery, Asiatic cholera, gastritis, typhilitis, and colitis. Asepsis of the alimentary canal is also desirable in chronic conditions in which fermentative processes are present. The substances which the author believes to be most efficient in combating the symptoms which have been mentioned are acetone, and sulphocarbonate of zinc. Other substances which have been used with varying degrees of success are arsenite of copper, quinine, salicylate or subgallate of bismuth, and crude petroleum.

AMERICAN JOURNAL OF OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

January, 1905.

1. A Conception of the Sphere of Gynæcology, By BOVÉE.
2. Further Results in the Use of a Modified Champetier de Ribes Balloon, By VOORHEES.
3. Accidental Perforation of the Uterus During Curettage. A Case with Bowel Injury and Resection of Four Feet of Small Intestine, By HESSERT.
4. A New Selfretaining Catheter and Vesical Irrigator, By WETHERILL.
5. Suture and Ligature Material, By CONGDON.
6. Removal of a Dermoid Cyst and a Decomposing Fœtus from the Uterus by Abdominal Section, By SUTCLIFFE.
7. Physometra, Pyometra, Hæmatometra, By MELLISH.
8. Pregnancy Complicating Fibroids, By BASHAM.
9. Albuminuria and Nephritis of Pregnancy and Labor, By STEWART.
10. Dermoid Cyst of the Ovary Complicating Labor, By THOMPSON.
11. The Early Diagnosis of Cancer of the Fundus with Report of Cases, By ROBB.
12. Cystadenoma of the Pancreas; Removed by Abdominal Section, By DUNNING.

2. Further Results in the Use of a Modified Champetier de Ribes Balloon.—Voorhees draws the following conclusions: 1. The modified Champetier de Ribes balloon is the best artificial hydrostatic dilator of the cervix. 2. The balloons are especially effective in dry labors to start pains. 3. Labor, if prolonged and protracted, from whatever cause, is hastened and in a large percentage of cases terminates spontaneously after their use. 4. The balloon is the best and most certain means of inducing labor for all indications. 5. In eclampsia and in placenta prævia the balloon has a field of usefulness which markedly diminishes maternal and fœtal mortality.

3. Accidental Perforation of the Uterus During Curettage.—Hessert concludes an interesting paper as follows: 1. Make an accurate diagnosis as to size, position, mobility, and consistency of the uterus. Determine the presence or absence of tumors of all kinds in connection with the pelvic organs. 2. Remember that the uterus is very friable, when curetting post abortum. Dilate the canal sufficiently, but first determine with accuracy the direction of the canal. A dilator with a single blade or rod is less likely to perforate the uterus than one with two or three blades. 3. Curette with the fingers if possible. A sharp curette is the most efficient when the operator is experienced. A volsella should never be used to withdraw material from the uterus. A placental forceps may withdraw omentum or gut. 4. Irrigation is seldom necessary, except for septic endometritis. Strong irrigating fluids should be avoided; boric acid is the safest if an irrigating fluid must be used. Caustic applications if indicated should be made with a swab. If the uterus has been penetrated with a probe and there is no visceral injury, it may be lightly packed, but not irrigated. If the perforation has been made with a curette, the intestine must be reduced and the wound sutured either by abdominal section or by vaginal section, according to the indications. If the conditions require it a vaginal hysterectomy should be performed. If the bowel has been badly injured it must be resected; both large and small bowel should be examined to determine the extent of the injuries.

1. **Convulsions in Childhood.**—Ashby states that a disposition to convulsions may be either hereditary or acquired, or both factors may be present. Rickets undoubtedly predisposes to convulsions. The exciting causes may be divided into the following groups: (a) Reflex—from the intestinal or respiratory tracts, from the internal ear, or from the nose or mouth. (b) Toxic, as in measles or influenza. (c) Central, as in meningitis or syphilis of the brain. (d) Epileptiform, when no cause can be found, and associated with belated intelligence. Convulsions in the newly born are usually reflex and not due to any brain injury. They are most common in artificially fed children, and the best cure is a wet nurse. A slight hemiplegia may ensue, and disappear after a few days or weeks. In a few cases the convulsions are due to defective brain development. Later in the child's life dentition undoubtedly plays a part in the production of convulsions, but the author dissents from the view that such convulsions may go on to epilepsy and insanity. Convulsive spasm of the glottis (child crowing or laryngismus) is practically always associated with rickets. Convulsions may be of cerebral origin, and due to meningitis, thrombosis, hæmorrhage, tumors, or syphilis. The nature of the fits does not lend much assistance in the diagnosis. Convulsions distinctly of a Jacksonian character are usually due to a syphilitic softening of the cortex of the brain. Slight general convulsions, frequently recurring without apparent cause, and with delayed intelligence, are of bad omen. In the severer forms of convulsions, there is usually high fever, one seizure is followed by another, and deep coma lasting from a day to a week supervenes. Hemiplegia is an important complication: it may be temporary, or persist for life and the limbs become spastic. Blindness may result, but is rarely permanent: in other cases the patient may come out of the convulsions deaf or aphasic. As regards treatment, subcutaneous injection of morphine is the most powerful remedy for quickly allaying the irritability of the nerve centres and checking the convulsive movements. A sixth months old infant may be given a fortieth of a grain. Chloroform acts quickly, but is only temporary.

2. **Pneumonia.**—Ewart, after reviewing the present day views as to the treatment of pneumonia, and the course and clinical stages of the disease, states that the definite objects are: (1) To arrest the morbid process, by other abortive measures than the missing antitoxine. (2) To restrict the invading host, though we cannot stop it. (3) To destroy or to neutralize the poison by the vital energies. (4) To hasten its elimination by every possible help. Among the principles of action are the following: Prompt, early, and assiduous treatment is necessary, for the opportunity for cure is brief. The disease may be aborted in its early stages. One of the great dangers is the failure to resorb the fibrin; hence it is most necessary to prevent its formation in

the first place. The removal of all obstructions is of the greatest importance: derivation by the *primæ viæ*, temporary starvation during the early stages, and acceleration of the lymph circulation by cardiac stimulants. Oxygen should be given continuously from the first, to support the heart. Bleeding by means of leeches is a routine part of the author's treatment. Bleeding from a vein should not be resorted to, except in severe cases. Leeching almost invariably relieves the pain in the side. Medication should aim at diuresis, diaphoresis, antifibrinosis, and absorption. To accomplish these various ends the following mixture is used: Iodide of potassium, 5 grains; liquor of ammonium citrate, 2 drachms; spirits of nitrous ether, $\frac{1}{2}$ drachm; aromatic spirits of ammonia, 20 minims, and chloroform water to half an ounce. A tablespoonful is taken hourly for six doses, and afterward every three hours. The citric acid checks fibrin formation by precipitating the calcium, which is an essential to clotting. The iodide of potassium dissolves and absorbs the fibrinous deposits. The diet, at first, should consist of whey. Alcohol is indispensable from the first, in moderation, as a substitute for food, and as a stimulant.

5. **Acute Leucæmia.**—Stevens reports a case of acute leucæmia occurring in a boy aged 17 years, which proved fatal on the nineteenth day of the illness. On the thirteenth day of his illness the leucocytes numbered 920,000 per c.m., and the excess was due to the large lymphocytes. The mode of onset and general symptoms suggested typhoid fever, tuberculosis, endocarditis, or some septicæmic condition. But there was no Widal reaction, the fever was most irregular, and there was marked priapism. Splenic enlargement was not noted until the thirteenth day, at which time the axillary and inguinal glands could also be felt.

7. **Human Piroplasmosis.**—Donovan tells us that in human piroplasmosis the parasites are found in the peripheral circulation, the spleen, the liver, bonemarrow, and in ulcers of the skin and intestines. In the blood they are found in the red corpuscles and in the leucocytes, but they are never numerous. They are small, about 1μ in diameter, are oval, bacillary, or pear shaped, and are always placed at the circumference. They are very numerous in preparations from spleen puncture. The author excludes entirely the genus *trypanosoma* as having any relation to the disease, but admits that there may be a *trypanosomoid* stage in the life cycle of *piroplasma* infection.

9. Two Cases of Suppuration of Goitre, By T. EVANS.
10. Reasons for Abandoning the Uric Acid Theory of Gout, By C. WATSON.
11. A Note on Senile Symmetrical Atrophy of the Skull, By F. P. WEBER.
12. On the Significance of Scars of the Genital Region in the Retrospective Diagnosis of Syphilis, By A. COOPER.

1. **Pruritus Ani.**—Ball divides cases of pruritus ani into three groups: 1. Those due to parasites, either animal or mycotic. Here the treatment is simple and effective, once the nature of the parasitic cause has been determined. 2. Those resulting from dermatitis of the cutaneous portion of the anal canal and surrounding skin. Under this head are included the protean group of eczemas. In acute moist forms the best applications are those which are emollient and unirritating, while in the chronic dry cases, highly stimulating applications are indicated. An ammonia soap is a very useful remedy. 3. Those in which the disease is essentially in the nerves supplying the affected area with sensation. These cases are quite incurable by any form of external application or internal treatment. The surgical measures hitherto adopted are: (a) cauterization of the skin down to the papillary layer; and (b) the excision of the implicated skin. The author has treated such cases by the simple procedure of division of the terminations of the sensory nerves to the affected skin. So far the cases are too few to generalize from; but they prove (1) that the operation gives immediate relief, and (2) that superficial sensation may be restored without recurrence of the pruritus. Should recurrence take place he would, bearing in mind the removal of the Gasserian ganglion for trigeminal neuralgia, seriously consider the removal of the posterior roots of the third and fourth sacral nerves with their ganglia.

5. **Duodenal Ulcer.**—Clogg reports three cases of perforated duodenal ulcer, in all three of which recovery followed early operation. The symptoms of the condition are most uncertain: in half the cases reported there is an absence of all symptoms previous to perforation. Perforation probably occurs in about half the cases. About sixty-five per cent. of those operated on in the first twelve hours recover; about twelve per cent. of those between the twelfth and twenty-fourth hours. But taking all varieties into account the mortality, at present, is about seventy-five per cent. Duodenal ulcers run a chronic course, and cicatrization is very infrequent. When perforation occurs the severe tearing character of the

pain, the severe collapse, the true abdominal rigidity, the facial aspect, and the rapid pulse all point to a peritoneal lesion. The prognosis is not so good as in perforated gastric ulcer, due to the fact that in the latter the earlier symptoms are more severe, and signs of peritonitis appear earlier. The diseases likely to be confounded with the condition are appendicitis, inflammation of the gall bladder, and suppuration around the colon. The author lays stress upon the following points in diagnosis: 1. A history of previous trouble. 2. The situation of the early pain in the right epigastric or hypochondriac region, higher up than in appendicitis. 3. The absence of previous symptoms. 4. The early rigidity and tenderness over the upper half of the right side of the abdomen. 5. The early tenderness on deep pressure over the lower ribs posteriorly and laterally. 6. The marked increase of pain on deep inspiration in quite the early stages. 7. The frequently observed elevation of the right half of the diaphragm. 8. The abscesses often contain gas, which is very uncommon in abscesses of the gall bladder and in the early stages of appendicitis.

9. **Suppuration of Goitre.**—Evans reports two cases of suppuration of goitre, occurring in persons of middle age. Recovery from the suppuration was slow, and was followed by disappearance of the goitre on the affected side, and diminution of it on the opposite side. In one case the suppuration was apparently spontaneous, in the other it was secondary to influenza.

10. **Uric Acid and Gout.**—Watson concludes from his clinical and laboratory observations that uric acid is not an important etiological factor in the production of gout. He believes that there is an infective element in the disease and that the uric acid is the feature which gives the inflammation its specific character. The chief source of infection is the alimentary tract, and an injudicious dietary acts in virtue of its influence on the bacteria present there.

12. **Syphilitic Genital Scars.**—Cooper states that the diagnostic value of genital scars in the retrospective diagnosis of syphilis is by no means easy to determine. He gives the following rough summary of his conclusions: 1. Genital scars are more common and more marked in hospital than in private practice. 2. In many cases of nervous or late forms of internal syphilis the genital region is free from scars. 3. A single scar on the skin of the penis suggests syphilis. 4. A single scar on the mucous membrane also suggests syphilis as a rule—occasionally the local chancre. 5. Multiple scars on the mucous surface of the penis suggest only the local chancre. 6. Multiple scars on both mucous membrane and skin also suggest the local chancre. 7. Inguinal scars, together with scars on the penis, suggest the local chancre. 8. An inguinal scar without any penile scar (if venereal at all) suggests gonorrhoea. 9. Extensive scarring of penis or groin, or both, suggests phagedena. 10. Genital scars, with scars on other parts of the body, suggest an ulcerating syphilide.

1. The Defensive Powers of the Body in Disease. By **MUIR**.
2. Extrauterine Pregnancy, By **KELLY**.
3. The Action of Poisoned Arrows Obtained from the Aros District of Nigeria, By **CHARTERIS**.

1. The Defensive Powers of the Body in Disease.—Muir observes that this subject may be considered in two parts, the first dealing with the histological changes visible with the microscope, the second with the subtle chemical substances in the cells and fluids of the body which aid in protecting the body and in curing disease. The chief cellular activities are included in the term phagocytosis. This includes the ingestion and digestion of bacteria within the cells. Not all bacteria which are ingested by the leucocytes are digested, they may even flourish and multiply within the cells. Bacteria which produce a local emigration of the neutrophil leucocytes will cause a neutrophil leucocytosis if the infection be sufficiently extensive; the converse of this statement is also true. With normally reacting tissues the leucocytosis increases with the extent of the infection. In infections in which leucocytosis is the rule the absence or diminution of such without improvement of the symptoms indicates severe toxæmia with interference with the supply of the defensive cells, or an inherent want of reactive power. With regard to the eosinophiles, whether the cells produced in excess act as direct phagocytes or indirectly produce some of the defensive substances, they evidently play an important part in the defense of the body. An abundant supply of leucocytes, free movement of the same, and a free flow of lymph favor local defense. The most important means of increasing phagocytic activity is supplied by active immunization or vaccination in the general sense. The defensive powers of the body, so far as the production of phagocytic cells is concerned, are sufficiently striking, but the antitoxic and bactericidal substances as ultimate weapons of defense, are more remarkable still. These and other antistances have this common property that they enter into chemical union with the substances on which they act, and show specific affinity in such combination.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending February 1, 1905:

- BROOKS, S. D.**, Surgeon. Placed on waiting orders effective January 27th. January 28, 1905.
- FROST, WADE H.**, Assistant Surgeon. Directed to proceed to Baltimore, Md., and report to the Medical Officer in Command for duty and assignment to quarters. January 30, 1905.
- GWYN, M. K.**, Passed Assistant Surgeon. Granted leave of absence for four months from January 19th. January 24, 1905.
- LAVINDER, C. H.**, Passed Assistant Surgeon. Detailed as inspector of unserviceable property at the Purveying Depot, New York, N. Y. January 28, 1905.
- LINLEY, W. J.**, Acting Assistant Surgeon. Department letter of January 3, 1905, granting Acting Assistant Surgeon Linley leave of absence for thirty days from January 16, 1905, revoked. January 28, 1905.
- LONG, J. D.**, Assistant Surgeon. Granted leave of absence for seven days from December 21, 1904, under paragraph 191 of the regulations.
- MAGRUDER, G. M.**, Surgeon. Granted extension of leave of absence for thirty days from January 22nd, on account of sickness. January 28, 1905.
- MONCURE, J. A.**, Acting Assistant Surgeon. Granted leave of absence for thirty days from February 1st. January 25, 1905.
- MULLAN, E. H.**, Assistant Surgeon. Directed to proceed to New York, N. Y. (Stapleton), and report to the Medical Officer in Command for duty and assignment to quarters. January 30, 1905.
- ROBERTSON, H. MCG.**, Assistant Surgeon. Granted leave of absence for six days from February 6th. February 1, 1905.

ROSENAU, M. J., Passed Assistant Surgeon. One day's leave of absence, January 28, 1905, under paragraph 189 of the regulations.

WICKES, H. W., Passed Assistant Surgeon. Granted leave of absence for one day, January 30th. January 28, 1905. To proceed to Philadelphia, Pa., and report to Surgeon Fairfax Irwin for special temporary duty. February 1, 1905.

Board Convened.

Board convened to meet at the marine hospital, San Francisco, February 1, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon W. G. STIMPSON, chairman. Passed Assistant Surgeon J. M. HOLT, recorder.

Appointments.

Dr. WADE H. FROST, of Virginia, commissioned as assistant surgeon in the Public Health and Marine Hospital Service. January 13, 1905.

Dr. EUGENE H. MULLEN, of Maryland, commissioned as assistant surgeon in the Public Health and Marine Hospital Service. January 13, 1905.

Resignation.

Acting Assistant Surgeon A. C. FRASER, resigned, to take effect January 31, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending February 4, 1905:

BRECHEMIN, LOUIS, JR., First Lieutenant and Assistant Surgeon. Reports as on temporary duty as examiner of recruits, San Francisco, Cal.

DAVIS, WILLIAM B., Lieutenant Colonel and Deputy Surgeon General. Promoted to the rank of lieutenant colonel, to date from January 19, 1905.

GIRARD, A. C., Colonel and Assistant Surgeon General. Granted thirty days' leave of absence, with permission to apply for a thirty days' extension.

HOFF, JOHN VAN R., Colonel and Assistant Surgeon General. Promoted to the rank of colonel, to date from January 19, 1905.

McCULLOCH, C. C., JR., Major and Surgeon. Promoted to the rank of major, to date from January 19, 1905.

OWEN, WILLIAM C., Major and Surgeon. Ordered to proceed from Fort Logan, Colo., to the United States Army General Hospital, Presidio of San Francisco, Cal., for treatment.

TORNEY, GEORGE H., Lieutenant Colonel and Deputy Surgeon General. Ordered, in addition to present duties, to take charge of the chief surgeon's office, Department of California, during leave of the latter.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 4, 1905:

ELMORE, B., Acting Assistant Surgeon. Appointed an acting assistant surgeon from January 24, 1905.

McDONNOLD, P. E., Passed Assistant Surgeon. Detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Dispensary, Washington, D. C.

MEANS, V. C. B., Surgeon. Detached from the Naval Hospital, Philadelphia, and ordered to duty at the Naval and Marine Recruiting Station, San Francisco, Cal.

MILLER, J. JR., Assistant Surgeon. Detached from duty with the Marines on the Isthmus of Panama, and ordered to the Boston.

ROSS, JOHN W., Medical Director, retired. Detached from duty under the Isthmian Canal Commission.

SMITH, R. K., Surgeon. Detached from the Naval Recruiting Station, San Francisco, Cal., and resignation accepted to take effect on February 28, 1905.

WEBB, U. R., Assistant Surgeon. Ordered to the Bureau of Medicine and Surgery, Navy Department.

Births, Marriages, and Deaths

Married.

BELL—BROCK.—In New York, on Monday, January 30th, Dr. Charles Thaddeus Bell and Miss Esther Hampton Brock.

CARMAN—BRODIE.—In Baltimore, Maryland, on Tuesday, January 24th, Dr. R. Perry Carman and Miss Roberta Brodie.

HATHAWAY—BAIRD.—In Woodstock, New Brunswick, on Wednesday, January 25th, Dr. Joseph H. Hathaway and Miss Ethel H. S. Baird.

MITCHELL—LUCAS.—In Eden Prairie, Minnesota, on Wednesday, January 25th, Dr. Ralph S. Mitchell and Miss Mabel H. Lucas.

MORGAN—BOOKER.—In Winchester, Virginia, on Thursday, January 26th, Dr. Daniel H. B. Morgan and Miss Isabelle Frances Booker.

Died.

ANTHONY.—In Syracuse, N. Y., on Thursday, February 2nd, Dr. Albert G. Anthony, in the forty-seventh year of his age.

BAGBY.—In Lane Village, Arkansas, on Sunday, January 29th, Dr. John Bagby.

BRENNEMAN.—In Norfolk, Virginia, on Saturday, January 28th, Dr. T. H. Brennenman, in the thirty-fifth year of his age.

BRIGGS.—In Petersburg, Virginia, on Monday, January 23rd, the wife of Dr. W. F. Briggs, in the thirtieth year of her age.

CONVERSE.—In Boston, Massachusetts, on Saturday, January 21st, Dr. Joseph H. Converse.

CUNNINGHAM.—In Newport, Rhode Island, on Sunday, January 29th, Dr. Edward Linzee Cunningham, in the ninety-sixth year of his age.

DOUGHTY.—In Matteawan, N. Y., on Saturday, January 28th, Dr. John H. Doughty, in the seventy-fifth year of his age.

ELLIS.—In Somerville, Massachusetts, on Saturday, January 28th, Dr. Charles C. Ellis, in the fifty-eighth year of his age.

ENOS.—In Jerseyville, Illinois, on Wednesday, January 18th, Dr. S. Cordelia Enos, in the sixtieth year of her age.

FREE.—In Baltimore, Maryland, on Friday, January 27th, Dr. Eli W. Free, in the eighty-first year of his age.

GREENE.—In Buffalo, N. Y., on Saturday, January 28th, Dr. Cordelia A. Greene, in the seventy-fifth year of her age.

HENRY.—In Denver, Colorado, on Monday, January 23rd, Dr. John A. Henry, in the forty-first year of his age.

HOFLING.—In Cincinnati, Ohio, on Sunday, January 22nd, Dr. A. J. Hofling, in the forty-eighth year of his age.

KOHLHASE.—In Panama, on Sunday, January 29th, Dr. Otto Kohlase, United States Navy, in the twenty-eighth year of his age.

McCONNELL.—In Somerville, Massachusetts, on Wednesday, January 25th, Dr. H. B. McConnell, in the thirty-fifth year of his age.

MCGRATH.—In New York, on Saturday, January 28th, Dr. Patrick J. McGrath, in the thirty-sixth year of his age.

O'HARA.—In Philadelphia, on Tuesday, January 31st, Dr. Michael O'Hara, Sr., in the seventy-third year of his age.

OLMSTED.—In Kansas City, Missouri, on Wednesday, January 25th, Dr. Charles C. Olmsted, in the sixty-sixth year of his age.

READ.—In Boston, Massachusetts, on Wednesday, February 1st, Dr. W. R. Read, in the seventy-first year of his age.

RICHARDSON.—In Ligao Allay, Philippine Islands, on Thursday, January 26th, Dr. Fred W. Richardson, of St. Paul, Minnesota, in the forty-sixth year of his age.

WALDO.—In Hulberton, N. Y., on Thursday, January 26th, Dr. Jesse Waldo, in the thirty-third year of his age.

WHITNEY.—In St. Augustine, Florida, on Sunday, January 22nd, Dr. William W. Whitney, in the seventy-seventh year of his age.

WOOD.—In Clearwater, Florida, on Monday, January 23rd, Dr. Samuel R. Wood, in the seventy-sixth year of his age.

LOCOMOTOR ATAXIA SUCCESSFULLY TREATED WITH ULTRAVIOLET RAYS.*

By J. MONROE LIEBERMANN, M. D.,
NEW YORK,

LATE ASSISTANT TO THE CHAIR OF SURGERY AT THE NEW
YORK POST GRADUATE SCHOOL AND HOSPITAL.

*Das Alte stirbt, es ändert sich die Zeit,
Und neues Leben blüht aus den Ruinen.*

SCHILLER (*Wilhelm Tell*).

There is a tendency among general practitioners to look upon patients suffering from locomotor ataxia as hopeless. They know of no certain relief for the distressing symptoms presented by the victims of this formidable disease. Nor can they be blamed for discouragement in the face of such apparently hopeless symptoms as the severe pains, incoordination, inability to walk, and failure of functional activity of bladder and rectum.

A gloomy prognosis is warranted in most cases, since locomotor ataxia is a disease which generally proves fatal and whose treatment demands our most intelligent effort, coupled with the strictest persistence and regimen, which must be maintained with mathematical precision. The diagnosis of a well advanced case of locomotor ataxia can be easily determined by even an intelligent layman. No disease presents such a sadly pathetic sight and is so characteristic in its leading symptoms. It is in the early stages of this disease, when the clinical picture is obscure, that most of us have erred in our diagnosis.

It is to the diagnosis of this so called preataxic stage that I wish to briefly direct your kind attention. Early diagnosis of any disease is of vast importance and this is especially true in the condition under consideration.

While our knowledge of the organic lesions underlying the symptoms which comprise the clinical picture of locomotor ataxia and which are,

* Read before the fourteenth annual convention of the American Electrotherapeutic Association, at St. Louis.

perhaps, as definite and well established as any associated with spinal pathology in the early stages of the disease, these changes are not clearly apparent, but revelations made by competent German and French observers and investigators seem to point to the fact that the rudimentary and primary destructive process occurs in the posterior columns with their roots and ganglia taking a longitudinal instead of a transverse direction.

To Duchenne belongs great credit for the clearness and precision with which he describes his remarkable investigation of progressive locomotor ataxia. He in fact supplied us the basis of our present pathological knowledge of the disease.

It is not incumbent on me to dwell upon the pathological anatomy of a disease with which you are by virtue of your special work so familiar, but in order to substantiate some statements that are to follow, I cannot entirely overlook this phase of the subject.

The portion of the spinal cord lying between the posterior nerve roots, as is well known, is altered in color, consistence, and dimensions. It becomes gray instead of white, hard instead of soft, and reduced in size. The grayish color predominates in the lumbar and lower dorsal regions. The posterior roots themselves are often atrophied and firmer in consistence and darker in color than in health. On making cross section of the cord it is found that the gray discoloration extends inward, involving the posterior columns.

Under the microscope we find the connecting elements of the cord are nearly destroyed and their place is usurped by a firm connective tissue made up of wavy bundles, enclosing here and there a few atrophied axis cylinders. The blood vessels participate in the morbid process; they become sclerotic, their lumen is contracted, while the adventitial sheath is hypertrophied and enveloped by a nucleated, fibrillar connective substance. It is evident that the increase of connective tissue in the posterior columns is the result of actual proliferation.

It is an established fact that the sclerosis of

areas of the spinal cord which are affected, is preceded by a stage of granular degeneration, itself due to morbid molecular disturbances of nutritional as well as functional morbid processes to which the spinal cord is subject. The nerve or its cells suffer all degrees of structural degeneration culminating in actual death, with an associated increase of connective tissue.

Morton, in discussing the pathological changes occurring in diseases of the spinal cord, pertinently states that in an extreme instance, after complete section of the nerve, the internodal nuclei increase in size, their protoplasm increases and becomes granular and compresses the myelin, ultimately separating into small fragments, which are soon absorbed, leaving only the mere sheath of the nerve. Atrophy of the cell or its axis cylinder and hypertrophy of the imbedding matrix are synchronous events. Nutrition, which is in abeyance in the former, is in a high degree of activity in the latter. There is evidently an interdependence of nutritional life between the two, for, the more rapid the loss of vitality of nerve elements, the more rapid the adventitious growth of the matrix.

You can readily judge from this short résumé of the pathology of locomotor ataxia, that the treatment must consist in restoring the destroyed nerve cells almost as it were from its ashes, stimulating its functional activity, and at the same time diminishing the nutritive activity of the connective tissue.

Electricity, in its diverse modalities, has long been looked upon as the only natural force that traverses the tissues to their innermost depths, and excites their irritability whether protoplasmic, as in the individual cell, or organic, as in the nerve structure.

The electric treatment in locomotor ataxia, should, therefore, always be central as well as peripheral.

Centrally, I use the ultraviolet ray. Peripheral treatment, as I exhibit it, consists of static electricity with the Morton wave current or the application of the wooden brush for ten or fifteen minutes daily.

After hearing Dr. Piffard's paper on radio-praxis, read at the Academy of Medicine, March, 1903, suggesting local cataphoric de-hæmatization before applying the ultraviolet ray, it appealed to me as a promising remedy in various diseases of the cord and I decided to try it. I have now treated 36 cases of locomotor ataxia with the following result:

Males, 34; females, 2. Ages range from 24 to 63 years. Four of these patients have been

restored to good health and are now able to resume their usual vocations. Twelve have been greatly benefited, the power of coordination has been restored, pain abolished, and the ability to use the upper and lower limbs without any assistance established. All are able to rise, dress, and undress themselves without any help and are sometimes able to perform such delicate operations as fixing the necktie or tying their shoes in a stooping position. In eighteen cases, the disease is apparently arrested with hope of further improvement and final restoration of different functions. Two died during treatment, one from lobar pneumonia, the other of erysipelas capitis.

These cases had for years received different forms of treatment, as the Matchkovsky modified Weir Mitchell suspension method, entire and partial body hot air treatment, hydrotherapeutical treatment, as well as the Franklin method. While some improvement had followed from these methods, none of them had made such gratifying progress as since submitting to the ultraviolet ray treatment.

For the purpose of de-hæmatizing I use the cataphoric electrode (with a round piece of lint) saturated with adrenalin chloride (1-1000). A pad (Fig. 1) with zinc plate is applied to the ab-

FIG. 1.—Pad used in de-hæmatizing the tissues. a. Made of unbleached muslin stuffed with cotton. b. Zinc electrode. c. Holder.

domen, leaving it on for 3-5-10 minutes. I use my static machine for exciting the ultraviolet lamp with the large Leyden jars as condensers. The lamp is connected by its conducting cords to the outer surface of the jars.

The question arises and I imagine I hear some of you asking how the ultraviolet ray cures these intractable and universally considered hopeless cases?

Perhaps we do not know, but a word as to its probable action will not be out of place. Little or almost nothing has been written on the phys-

biological effects of ultraviolet ray on living tissues and in all my research I failed to find a single article on the physiological effects of ultraviolet ray on the tissues underlying the skin. Probably the reason being that the ultraviolet rays are absorbed by the skin. But since dehæmatization permits the ultraviolet ray to traverse the skin, it opens a new field of study for this particular part of the spectrum, where its action was formerly especially investigated in superficial diseases of the skin. Freund, in his excellent and elaborate article on phototherapy, goes into the description of the physical properties of the ultraviolet ray, but says not a word on its physiological effect on the tissues.

We do know that the ultraviolet ray light is of a short wave length and of very high rate of vibration (more than 800 billion vibrations a second) and like other invisible forms of vibration, has its physiological effects on animal tissue, which can only be understood by clinical manifestations.

With this clinical experience of ultraviolet ray in 36 cases of locomotor ataxia, and about 20 other cases of nervous diseases, I still feel myself not competent enough to present to you a positive statement of the influence of ultraviolet ray on the protoplasmic cell. I can only suggest a theory of action, namely, that its powerful stimulating effect induces more activity in the natural healthy cell and diminishes the nutrition of connective tissue setting up a more active local metabolism.

Another hypothesis, resembling that advanced by Professor Sajous as to the rationale of the curative action of the Röntgen ray, is equally applicable to the ultraviolet ray, namely, that it induces a local accumulation of heat energy and a congestive process through which neutrophile leucocytes are caused to immigrate into the vicinity of the degenerated cellular elements into normal and healthy cells.

And in this connection I desire to record my conviction that to facilitate this result it is all important to maintain the normal alkalinity of the blood and secretions throughout the entire treatment.

While the dispute among chemists and physicists is still in vogue as to whether the ultraviolet ray traverses the dehæmatized tissue, the fact remains that when applied in a proper and cautious manner, it exercises a remarkable tonic effect upon all underlying tissues, and acts as a restorative to the different portions of the nerve structure as have been partly destroyed eventually restoring their function.

The application of the ultraviolet ray to dehæmatized tissues should be made with great care

FIG. 2.—X ray taken of left foot, proving faulty diagnosis of flat foot.

and judgment. In my opinion it is a very powerful remedy and should never be applied to more than two localities at each séance, and the area should be varied so that every day a different region of the cord is treated. I divide the spine into three regions, cervical, lumbar, and sacral, treating these alternately or in rotation.

One characteristic and almost invariable effect of the treatment with the ultraviolet ray in combination with the electric stimulation of the peripheral nerves and their end organs, is the improved general nutrition of the patient. They all make a rapid increase in weight and improve in general health.

Complications associated with these reported cases of locomotor ataxia: 8 had secondary and tertiary syphilis; 3 had pulmonary trouble; 29 were victims of marked anæmia; 7 had cardiac lesions; 2 had diabetes; and 34 showed excess of phosphates and uric acid. This excess amounted from 8 to 14½ grains to the ounce.

The first case treated by me with ultraviolet ray began in March, 1903.

The routine treatment to which I have adhered in locomotor ataxia consists of:

- (1) A warm half bath at night before going to bed, with light massage.
- (2) Ultraviolet rays in sittings of ten to thirty minutes, three times a week.
- (3) Static electricity by means of the Morton wave current or wooden brush daily, fifteen to twenty minutes.

CASE I.—Charles K., aged 56 years, merchant. I saw him first in 1900, in consultation with another physician and diagnosticated the case as locomotor ataxia, which diagnosis was ridiculed by another consultant later on. Did not see him again until the early part of 1902, when he was brought to the office by a guide. All his symptoms showed him to be a typical case of locomotor ataxia. Treated him until August, 1903, by x ray, also using hydrotherapeutics and massage. Improvement, if any, very slight.

August 12, 1903, first application of ultraviolet ray to lumbar region (where the most pain occurs at night). Pain diminished that night and could sleep four hours at a stretch. Raying continued 10 to 20 minutes daily.

September 16, 1903, he was able to use right hand to grasp objects. Right leg showed some responsive reflex. Felt better in general.

February 10, 1904, came to the office with a guide and using only one cane in the right hand. Reads better. Left hand and leg were improving. Received ultraviolet ray three times a week.

July 15, 1904, was able to go down to his place of business, but still unable to write a letter. Had been signing checks for the last four months. Coordination then perfect. Pains have entirely disappeared.

CASE II.—J. C., builder, June 21, 1902, 39 years of age, well proportioned. This is the most typical preataxic case I have ever seen; this opinion was corroborated by several of my colleagues who examined the patient.

Five years ago the patient was exposed for seven or eight hours to wet and cold, during a storm, and was unable to procure change of clothing for some hours. The next day was unable to get out of bed, owing to pain in the legs and back. Had chancroid twenty years ago, but no constitutional symptoms. Was treated for rheumatism until he applied to me.

Called June 21, 1902, with complaint of rheumatic pain in lumbar region. Examination disclosed lack of coordination, but this could be noticed only when having his eyes closed. He could lift either leg steadily into any position, or stretch out his arms and keep them out, or touch his nose with the forefinger of each hand in turn, while he was allowed to see what he is doing, but if his eyes were shut, his limbs at once became uncertain and unsteady in their movements, and comparatively powerless.

Complained of severe stabbing, boring, and lightning like pains in the lower lumbar region extending to the feet along the outer side of the metatarsal bones of the little toe.

Was treated with static electricity in connection with general medication, with no particular improvement until end of one month. After sixteen applications, this pain was much relieved, while coordination and the eyesight began to improve. Functional activity of bladder and bowels began to be noticed.

February 26, 1904, had had 186 applications of ultraviolet ray. He came to office with a guide, went down town to his business for a week and was able to attend to same. Coordination was improved; no pain; bowels and bladder controlled.

July 20, 1904, had received 258 applications. Walked along the street without either guide or support. Only by careful examination could I find some tenderness in any part of lumbar region. Other symptoms had almost entirely disappeared. Attended to his business daily for five to six hours. Appetite good. Had gained 19 pounds since February last. Case discharged and considered cured.

CASE III.—J. F., 28 years old, United States

cutter by occupation. Eight years ago after extreme exposure to wet and cold, was laid up for nineteen months. All this time he was treated for rheumatism. Had pain in the lumbar region, extending to the left leg and down to the heel. Was sent to an orthopaedic surgeon, who advised him to wear arch supporting plates.

The interesting feature in this case was the arthropathic condition of the ankles of both legs, more marked in the left, and accompanied by a bursa. Eight or nine years ago he was exposed to extreme wet and cold for six or eight hours and was unable to get out of bed next morning. Two days after was able to go down to his business. Being a cutter, was forced to stand much on his feet. After a few hours' work was brought home in a cab and was "laid up," as he said, for nineteen months, being all this time treated for rheumatism. He was sent to Mount Clemens, Mich., and to Hot Springs, but obtained no material relief. Was then advised to see an orthopaedic surgeon, who diagnosed the case as rheumatism in combination with flat foot, and advised arch supporting foot plates. He was from time to time under treatment by several competent physicians in this city, all agreeing in the diagnosis of rheumatism. One orthopaedic surgeon was quite frank in stating that he could not make a proper diagnosis, but if permitted to open the joint, he would be able to diagnosticate the case properly and to treat it accordingly. There was no specific history. The patient had had gonorrhoea several years before. One young surgeon was quite insistent as to the necessity of removing the bursa, and the patient was, therefore, recommended to me for this operation. On examination, I found an enlarged left ankle joint with synovial sac situated behind the tendo achillis. There was no pain on pressure, but the patient suffered severe boring, lightning like pain from the hip down to the heel, so severe that for the purpose of relief he had to lift the heel almost two inches from the ground while walking. Romberg's symptom was absent. Status on the right foot was better than on the left foot. Westphal's symptom (knee jerk) was entirely absent in the left, and diminished in the right knee. There was boring, lightning like pain in the left leg and slight pain in the right. Extreme numbness and drawing pain were present in the left leg, but very little in the right. If we added the Argyll Robertson symptom in combination with disturbances of micturition and peculiar numbness around the waist, the picture of locomotor ataxia was complete.

According to Virchow, atheromatous changes occurring in tabetic joints, due to a predisposition of the bones to faulty cellular metabolism, resulting from nervous disease of the cord, are not very rare. Charcot observed them in 107 cases; in the knees in 78; hip, 31; shoulder, 21; tarsus, 13; elbow, 10; ankle, 9 times.

This inflamed joint symptom misled some very competent practitioners in their efforts to make a correct diagnosis, and possibly led those who had made the right diagnosis to consider the case hopeless. Flat foot was tested for by impression method and x ray (Fig. 2). X ray of the arch

FIG. 3.—Showing edematous condition of legs and ankle joints.
A. Situation of bursa.

of the left leg proved flat foot to be a faulty diagnosis.

The synovial sac and the whole left ankle (Fig. 3) were treated with the galvanic current, and after one month's treatment the bursa or synovial sac disappeared; the joint diminished in circumference fully $1\frac{1}{4}$ inches (Fig. 4).

The ultraviolet ray was applied to lumbar region from the first day, from ten to fifteen minutes, three times a week; there was also peripheral treatment with static electricity daily.

March, 1904; had now received six months' treatment. The joint was perfectly normal and the patient had discarded the instep support. He had no pain, and stood on his feet seven or eight hours a day. Coordination was restored. The Argyll Robertson symptom still persisted. The knee reflex was now present, is perfect in the right, but still diminished in the left leg.

July 20, 1904; the patient had no pain. All symptoms of locomotor ataxia were gradually disappearing. The patient worked steadily seven to eight hours a day, standing on his feet.

CASE IV.—Miss A. L., 42 years of age, unmarried, lady of leisure; corpulent, weight 156 pounds, was brought to my office July 16, 1903, in an invalid chair, and complained of severe pain in the lumbar region and hips, extending down the legs below the patella. She attributed this condition to a fall in the cellar that occurred four years previously. Nine years before, she was laid up in bed for four weeks with rheumatism, due to severe exposure to cold and wet while driving in the Catskill mountains. Menstruation was irregular and painful. There was a specific his-

tory with constitutional symptoms, dating back twelve years.

Examination showed marked anæsthesia below the waist and down to the legs, also in the upper limbs. All the important symptoms of locomotor ataxia, as Argyll Robertson, Romberg, and Westphal symptoms were distinctly present. Treatment was begun at once. The ultraviolet ray was applied alternately with the x ray to the lumbar and cervical regions, and peripheral treatment with static electricity was used daily.

In this case attention was paid to reduction of superfluous adipose tissues through muscular exercise in the limbs, with massage and gymnastics. After one month's treatment the patient lost 12 pounds, and was able to walk two or three blocks.

February 13, 1904, pains in the limb were felt only once in a great while, and the reflex in the knee reappeared. The Argyll Robertson pupil persisted, although the incoordination diminished.

By July 20, 1904, the patient had received 146 ultraviolet ray applications. She was able to come to the office from her home, a distance of 14 blocks, was able to use her hands to dress herself, the Romberg's symptom was much less apparent, she had perfect control of bladder and rectum and suffered no pain.

In an overwhelming majority of these cases the disease manifests itself in the lumbar and sacral region, being thus limited for a long period, then advancing slowly upwards. The peculiar tired feeling, occurring mostly in the knees and ankles, and that is not relieved by rest, is present in all the cases in combination with the lightning like pains of such severity that usually the patient is forced to cry out. It is for the physician to dif-

FIG. 4.—Showing condition of legs and ankle joints a few months later.—Note distinct lines of tendo achillis and entire absence of bursa.

ferentiate between the tabetic and rheumatic pains. Tabetic pains are paroxysmal and the intermissions are complete; tabetic pains are neither aggravated by motion nor relieved by rest, while rheumatic pains are. Tabetic pain is usually relieved by pressure, while rheumatic pain is thus aggravated. Hyperæsthesia is usually present with tabes, and almost always absent with rheumatism. The patient's description of the tabetic pain, comparing it to tearing, boring, and the jumping of a violent toothache, is of great significance. That peculiar form of illusive sensation known as the girdle constrictor, is found in various situations, according to the level of the diseased part of the cord, whether low or high.

The following are helpful guides in the diagnosis:

Romberg's Symptom: Swaying of the body and inability to maintain the erect position with eyes closed; always present.

Argyll Robertson Symptom: Loss of pupil reflex to light, but reaction to accommodation retained.

Westphal's Symptom: Absence of patellar reflex, if carefully tested, can always be found.

Another and a very important symptom in the diagnosis of locomotor ataxia in its earliest stages is Frankel's hypotonia.

A few words as to its ætiology. Excluding all predisposing nervous and specific causes (syphilis being no more prolific in causing this than any other exhaustive disease, even excessive venery). I am quite disposed to consider severe and sudden exposure of cold and wet as a prominent ætiological factor. Feinberg has demonstrated that cold applied to the cord of animals may produce myelitis.

If excessive venery was as frequently a cause as is generally believed and confidently asserted in our textbooks, our large cities would be literally overrun with atactics. On the other hand, our male population would indeed be in a very deplorable state if masturbation and venereal excesses alone would produce locomotor ataxia.

In conclusion, it may be set down that not all, but some cases of locomotor ataxia readily respond to a judicious and persistent application of the ultraviolet ray, while others are decidedly obdurate and will try our skill to the utmost. The success thus far attained warrants us in holding out hope in all cases not too inveterate or too complicated. And, if in the incurable cases we can succeed in relieving or at least greatly mitigating the severe pains, in partially or wholly restoring the power of coordination and overcoming the ocular disturbances, we shall win the unmeasured gratitude of our suffering patients, and the supreme satisfaction of self absolution and self approval.

But let no one who intends to utilize this particular modality of electricity flatter himself that he can succeed, except by exercising eternal vigilance as to the thoroughness of his methods, the scientific perfection of his technique, and his constant exercise of his professional discretion, learned from the most painstaking clinical observation. If inclined to fall into haphazard methods which have heretofore been only too common, it were far better that he should never attempt the treatment.

If this brief and by no means exhaustive paper shall be the means of stimulating further investigation and of arousing some reasonable hope in many cases where hitherto there has been no hope, the author's highest ambition will have been realized.

THE PATHOLOGY OF CEREBELLAR TUMORS.*

By T. H. WEISENBURG, M. D.,

PHILADELPHIA,

INSTRUCTOR IN NEUROLOGY AND NEUROPATHOLOGY IN THE UNIVERSITY OF PENNSYLVANIA; ASSISTANT NEUROLOGIST TO THE PHILADELPHIA GENERAL HOSPITAL.

(Concluded from page 283.)

It may be impossible, as in Spiller's second case, to make a correct diagnosis in sarcomatosis of the brain and of the pial covering. Extensive alteration may cause few clinical symptoms, because the soft tumor masses grow in the pia and about the cranial nerves and spinal roots, and may produce little or no compression or destruction of the nervous tissue. Spiller insists upon the importance of remembering this fact, for when evidences of sarcomatosis are found, the case is an inoperative one.

Occasionally the process may invade the brain substance, while the nerve roots may escape. It is, according to Spiller, because of this escape of the nervous tissue in many cases that a correct diagnosis of the extent of the process may be impossible.

The infiltration of the pia may resemble that

* From the Neuropathological Laboratory of the University of Pennsylvania.

caused by syphilis or tuberculosis. Again, as in Nonne's case, the macroscopical examination may be normal.

Sarcomatous tumors, according to Westphal, occur more often in the young. When tumors occur in the posterior cranial fossa they have a predilection for the cerebellopontile angle and the internal auditory meatus.

Isolation of the sarcomata whether of the cerebellum or of any other region of the brain are, next to fibromata, among the most favorable forms of tumor for surgical removal. Of course the question of multiple sarcomatosis must always be carefully considered when deciding upon operation. With regard to surgical procedure the hard non-infiltrating sarcomata are the most favorable. Experience shows, however, that a sarcoma which appears to be infiltrating when the brain and tumor mass are first exposed, is often separable from the brain substance.

Syphilitic Growths.—Gummata are rarely found post mortem, although they are possibly the most common cranial growths. They are especially rare in the cerebellum. The resemblance between this growth and tuberculoma has already been discussed. In a recent article Mills recorded two cases in which the diagnosis of a tumor in the cerebellopontile angle was made. At the necropsy no tumors were apparent, but microscopically in the first case a diffuse syphilitic basal meningitis was found and in his second case besides a meningitis at the base, there were numerous areas of softening throughout the brain, extending from the gray into the white matter. These areas of softening were yellowish red in color, soft in consistence, and were well defined from the surrounding brain substance. Microscopically, there was an intense round cell infiltration about the blood vessels and within the tissues.

These cases illustrate well the nature of syphilitic new growths. It is well known that a syphilitic basal meningitis, or meningoencephalitis, may attack any cranial nerve or combination of cranial nerves, but according to Mills they show a predilection in favor of the nerves from the second to the seventh inclusive, of these the fifth perhaps most frequently escaping.

Syphilitic growths are rapid in development, but it must be remembered that the various pathological conditions which lead on to these growths have been long present.

Fibromata.—These tumors are rare, but they are relatively more frequent in the cerebellum than in the cerebrum, and especially in the cerebellopontile angle. This has been better recog-

nized within the last few years, because of the relatively successful surgical removal of tumors growing in this area.

A fibroma invading the cerebellopontile angle may be only a part of a general neurofibromatosis; this, however, is rare, or, what is more common, it may be the only expression of this process, a central neurofibromatosis. The growth is slow, and generally is unilateral, although in rare instances it may be present on both sides. Henneberg and Koch pointed out that these tu-

FIG. 2.—Fibroma growing from the left acoustic nerve compressing slightly the left lateral lobe of the cerebellum and the lower surface of the left temporal lobe.

mors are more often found on the left side in the ratio of three to two. In the cases reported by Dr. Mills, the pathological reports of which are here given, the neoplasms were on the left side. In an examination of the tumors situated in the pons, medulla oblongata and the cerebellum, we found that the majority were on the left side. It seems, therefore, that tumors of these areas are more prone to grow on the left side.

The fibroma may be as small as a cherry or the size of a large egg. The growth is firm, hard, nodular, and has a distinct capsule surrounding it. It is loosely attached to the brain by an atrophic nerve trunk, a few blood vessels or a meningeal process, and these attachments may be easily ruptured. These tumors are in organic relation, especially with the acoustic nerve, and more rarely with the trigeminus and facial nerves. They nearly always grow from the endoneurium

and rarely from the peri- or epineurium. Consequently we may find medullated nerve fibres either in the periphery of the tumor or in its centre. As a rule, if the process involves the other cranial nerves, we have a general neurofibromatosis.

The fibroma may undergo a cystic, fatty, or myxomatous degeneration. Very often in its advanced stages it may assume a sarcomatous tendency. Histologically we find a connective tissue structure with entire absence of nerve elements, except sometimes a few medullated nerve fibres either in the periphery or its central part. These are remnants of the nerve on which the fibroma grows and should not be mistaken for a part of the new growth. Most writers persist in calling these tumors neurofibromata. The best example of a true neurofibroma is the amputation neuroma, therefore, a fibroma would be a better term for these growths.

In a number of cases of fibroma of the acoustic there were associated cortical changes. Henneberg and Koch reported hyperplasia and hypertrophy of the glia cells of the cortex, especially of the deeper layer, and in another case endoelioma and psammomata of the dura mater. Fraenkel and Hunt made a similar observation. In another case reported by these authors there were protrusions and minute herniæ attached to and sometimes perforating the dura. Histologically, these consisted of large cells of the spindle type and of glia cells.

At times the fibromatous process may involve the whole of the intracranial portion of the acoustic. In a case of Alexander and v. Frankl-Hochwart, an anatomical examination of the labyrinth showed a degenerative atrophy of the cochlear nerve, the spiral ganglion, the organ of Corti, and the striæ vasculares.

These tumors compress greatly the lateral lobes of the cerebellum, the pons, and the medulla oblongata. In one of Dr. Mills's cases the temporal lobe was compressed. Because of the slow growth and the nature of the tumor, clinical symptoms may not appear at all, or only late in the disease. In one of Dr. Mills's cases there were no symptoms of such a growth, the tumor being found at necropsy.

The following pathological report of two cases of fibroma in the left cerebellopontile angle are from the service of Dr. Mills. They are referred to by him in the discussion of tumors of the cerebellopontile angle, the first extensively, the second briefly. The clinical report of the second case is appended:

CASE I.—A tumor 3 cm. wide and 2½ cm. in

length anteroposteriorly was found in the left cerebellopontile angle, compressing slightly the forward part of the left lateral lobe of the cerebellum and the under surface of the temporal lobe. The pons and medulla oblongata were not compressed. There was marked internal hydrocephalus. Microscopical examination showed it to be a fibroma.

CASE II.—A tumor (Fig. 3) 5 cm. wide and 3 to 4 cm. in length anteroposteriorly was found in the left cerebellopontile angle. The tumor was very firm and nodular, and compressed considerably the under surface of the left lateral lobe of the cerebellum and the left side of the pons. At no place did the tumor infiltrate the brain tissue, and it could be entirely enucleated. Microscopical examination showed it to be a fibroma.

Cysts.—Cystic degeneration of gliomata and sarcomata are very common, especially if they are situated in the cerebellum. This has been discussed when speaking of sarcoma. Other tumors, as fibroma and carcinoma, are prone to undergo cystic change, but more rarely. Some authors believe that the whole tumor may disappear and only a cyst remain. In other cases only a microscopical examination will detect a small tumor mass in the walls of the cyst. Spiller has pointed out that the wall of a congenital cyst may be the starting point for a neoplasm, and this possibility should not be ignored.

The most common cystic changes found in the brain are due to parasitic growth, the cysticercus cellulosa and the echinococcus. These, however, are so rare in this country that they will not be here discussed.

Cysts due to traumatism are recorded, but their genesis is by no means clear. Congenital

FIG. 3.—Fibroma growing in the left cerebellopontile angle compressing the lower surface of the cerebellum and the left side of the pons.

cysts are rare. They are probably offshoots of the primary cerebral vesicles. Dermoid cysts have been recorded as occurring in the cerebellum in several instances.

Carcinoma.—Carcinoma of the cerebellum is rare. This form of neoplasm is always secondary and grows from the dura or in the substance of the brain. Saenger recorded infiltration of the cerebral pia with cancer cells. The possibility of toxic changes must be considered, as it is not improbable that through intoxication caused by a carcinoma elsewhere in the body, symptoms of brain tumor may be present.

Osteoma.—In several instances an osteoma has been described as occurring in the cerebellum. It is probable that these growths are not primarily of bone formation, but are the result of calcification of such tumors as tuberculoma, fibroma, sarcoma, and even lipoma. Other neoplasms, as adenoma, lipoma, angioma, psammoma, and cholesteatoma are hardly ever found in the cerebellum, so they will not be discussed. It must also be remembered that aneurysm of the vertebral or basilar artery may give symptoms of cerebellar growth.

The Influence of Cerebellar Growths.—At the operation when the dura is removed there is nearly always increased tension and the parts may bulge. The surface of the cerebellum is flat and the fissures may be abolished. The pia covering the neoplasm is generally poor in its blood supply. The tissues near the growth may be softened. If the tumor is in the lateral lobe of the cerebellum it may compress the fifth, seventh, and eighth cranial nerves. The occipital lobes may even be compressed through the tentorium. If the cerebellar tumor is large it may compress the corpora quadrigemina, pons, and the medulla oblongata, and these structures may be flattened or deformed. Pressure may also be exerted upon the cranial nerves at the base of the brain. The influence of cerebellopontile growths upon surrounding structures has already been discussed.

The cerebrospinal fluid is almost always increased in cases of cerebellar tumor, because pressure is exerted upon the communication between the lateral ventricles and the fourth ventricle, or upon the veins of Galen, which convey the blood from the chorioid plexus to the sinus rectus. Because of this internal hydrocephalus undue pressure is brought to bear upon the different cranial nerves, as the optic and olfactory. The optic chiasm may be directly compressed through pressure from the third ventricle.

Alterations in the posterior roots and the posterior columns of the spinal cord have been re-

corded as occurring in conjunction with tumors of the brain. Such changes have been also found by Dr. Spiller. According to Batten and Collier they are especially present in cerebellar growths, and are due to the increased pressure. Dinkler and Becker believe that toxic or nutritional changes are at fault.

Tumors of the Fourth Ventricle, Medulla Oblongata, Pons, and Chorioid Plexus.—It is not in the province of this paper to consider *in extenso* neoplasms of these areas, but inasmuch as these growths sometimes give symptoms of cerebellar involvement, they will be briefly considered.

Tumors of the fourth ventricle and of the medulla oblongata may give no appreciable clinical symptoms. They may either be cystic or hard, and may grow in the substance of the medulla oblongata. This is especially true of parasitic and congenital cysts. Hunt recorded two congenital cysts of the fourth ventricle in which the cerebellum was greatly compressed and yet there were no cerebellar symptoms.

Neoplasms growing within or upon the corpora quadrigemina nearly always compress the middle or the lateral lobes of the cerebellum. They also cause internal hydrocephalus. Two such specimens are in our collection.

Tumors of the pons may cause pressure symptoms upon the cerebellum, or the growths may involve the middle cerebellar peduncles. Growths of the chorioid plexus, as in a case of Arnold's, where a psammoma of the size of an apple was found, may compress the pons, medulla oblongata, and the cerebellum.

Tumors in the Cerebrum Giving Symptoms of Cerebellar Growth.—Ascherson recorded an instance in which a sarcoma was found in the centrum ovale of the left side in the upper motor area. This neoplasm measured $1\frac{1}{2}$ by $2\frac{3}{4}$ inches, and could easily be enucleated. It caused a compression of the lateral ventricle in the same side. This author cites Raymond as having recorded an almost similar case. Ascherson is of the opinion that the cerebellar symptoms were due to pressure exerted through the lateral ventricle, and he emphasizes the importance of early symptoms before those of pressure are apparent. In this connection the fact that tumors of the post-parietal cortex or subcortex, may give unilateral ataxia should be borne in mind. The diagnosis between post parietal and cerebellar tumors is given in the paper of Dr. Mills.

Abscess.—Chronic otitis media is the most frequent cause of abscess in the cerebellum. It may be due to such other causes as traumatism or may be a part of a general pyæmic process,

but these instances are uncommon. The abscess occurs mostly in the anterior outer part of the cerebellum, and is generally single. It may involve also the adjoining temporal lobe. The abscess may be encapsulated or it may keep on forming pus. Surrounding it, œdema and softening of the brain substance are found. Pus may travel along the facialis and acousticus, and cause extradural abscesses. Hydrocephalus, sinus thrombosis, and thrombophlebitis are frequent complications.

Internal Hydrocephalus.—This condition is most often caused by a brain tumor, but it may be congenital or acquired. Spiller recorded an instance in which the symptoms were those of cerebellar tumor, and at the necropsy the cerebral ventricles were much distended, but the fourth ventricle was of normal size. The aqueduct of Sylvius was almost entirely occluded when examined, and the occlusion must have been congenital or have occurred early. Byrom Bramwell recorded a similar case, but here a localized meningitis caused a closure of the foramen of Magendie. The possibility of internal hydrocephalus should always be kept in mind when a cerebellar growth is considered.

Symptoms of Cerebellar Tumor Without Lesions.—In a very important paper, Nonne called attention to those cases in which the majority of the symptoms of brain tumor were present, and in which either spontaneously or under mercurial treatment the symptoms disappeared, leaving, perhaps, a partial optic nerve atrophy. There was no reason in any of the eight clinical cases he reported to suspect syphilis.

He also records three similar cases with necropsy, in two of which symptoms of a tumor in the posterior cranial fossa was diagnosed. At the necropsy in the first case, internal hydrocephalus was found. On the floor of the fourth ventricle, opposite the posterior medullary vulum, there was a hard, long, yellowish white structure, which obstructed the flow of the cerebrospinal fluid. Microscopically this was found to be a fibroma. In his second case, internal hydrocephalus was also found, this being caused by a sarcoma of the ependyma of the floor of the fourth ventricle.

He further records three cases with necropsy in which there was no internal hydrocephalus. Nonne also reports cases of internal hydrocephalus which gave largely basal symptoms due to various causes, and which terminated either in death or recovery. He leaves us in doubt as to what is the cause of such a condition.

Dr. Spiller has very kindly given me the records of such a case occurring in his service.

Woman, 44 years of age, domestic, past history unimportant. Two and one half years ago the patient began to have violent headache in the left cerebellar region. This headache became more severe and became localized in the left parietal region, where there was also great tenderness to pressure. She had an ataxic, drunken gait, and would fall to the left or backwards when walking. Extreme vertigo was also present, especially when she was lying on her left side or walking. Power was diminished in the lower limbs and sensation was also somewhat impaired. The patellar jerks were absent. There was no albumin in the urine.

Dr. Roberts operated at the point of great tenderness in the left posterior parietal region. There was nothing abnormal found and the brain appeared to be in a healthy condition.

The patient's symptoms steadily disappeared, the pain in the head became better and in a short time she seemed almost well.

Another case was studied by me repeatedly.

This woman was in the nervous wards of the Philadelphia General Hospital in the service of Dr. Spiller. She was 52 years of age, denied venereal history, and her past history was unimportant. Five years ago she began to have violent vertical headache, which has persisted more or less since. One year ago she began to have objective vertigo, and convulsions, Jacksonian in type, which always involved the left side of the face, and the left arm and leg. Sight also became poor at that time, and her memory was not as good as formerly. In my examination she showed a paresis of the left arm and leg, these being spastic, and the reflexes were exaggerated. The Babinski sign was present on this side. There was also a paresis of the lower distribution of the left seventh nerve, and a paralysis of the left abducens and the left fifth nerve, both in its motor and sensory distribution. Optic neuritis was present in both eyes.

On protruding her tongue she had a clonic to and fro movement which became apparent on talking or moving the tongue. She became steadily worse and finally was comatose. The urine examination was negative. She rallied, however, her symptoms steadily disappeared and she was discharged from the hospital four months afterwards, the only remaining symptom being a dimness of vision.

These two cases are similar to those recorded by Nonne. No adequate explanation for them can be given.

Lesions of the Cerebellum Without Symptoms.—These lesions may be either congenital, acquired early in life, or may be tumors. It is not surprising that injuries to the cerebellum early in life or that tumors of slow development which occur in the same period give no appreciable symptoms, because the functions of the cerebellum in such cases have probably been assumed by other parts of the brain. Lesions of the lateral lobes of the cerebellum are less liable to cause symptoms than when they implicate the

entire cerebellum. Spiller recorded three cases of lesion of the cerebellum in which there were no symptoms, and he also reviewed the literature upon this subject. In his first case one cerebellar lobe was smaller than the other, and it was sclerotic. In the second case there was a tumor upon the corpora quadrigemina in which the lateral lobe of the cerebellum was compressed. The third was one of tumor within the vermis.

Cases are recorded in which tubercles involved an entire lateral lobe and gliomata and cysts occupied the middle lobe, and yet there were no symptoms. Oppenheim refers to a case of Putnam's, where the only symptom for years was an optic nerve atrophy, in which at necropsy a cyst of the cerebellum was found. He also refers to Bramwell's case, where in a thoroughly studied case no symptoms were apparent, while at necropsy four tumors were found.

It can readily be understood why symptoms may not be apparent in a gliomatous tumor, because of its infiltrating character, and in tubercles, in which the axis cylinders are retained; but it is difficult to explain the absence of symptoms in the other instances.

The notes of the case of cerebellopontile tumor, as shown in the illustration, Fig. 3, and Case II of this paper, were furnished by Dr. Mills. The patient was seen by Dr. Mills in consultation with Dr. W. W. Keen; she was also examined in consultation by Dr. W. G. Spiller. The tumor sprang from the eighth nerve, and the chief focal symptoms were one sided deafness, tinnitus, facial monospasm, hypæsthesia of one side of the face, nystagmoid movements, slight paresis of right abducens, and vasomotor and cardiac disturbances. Severe headache, nausea, vomiting, and optic neuritis were also present.

This patient was a married woman, 30 years of age, five of whose maternal relatives had died of cancer. Four years before coming under observation the ossicles of her left ear were removed, on account of an annoying tinnitus, but without the desired result. About one year later she began to suffer from severe headache. The next year slight optic neuritis was observed in both eyes, the neuritis going on to atrophy and blindness, which was complete in less than two years. Headache, nausea, vomiting, and depression were recurring symptoms, and taste and smell were impaired. During two or three years she was treated for various complaints as anæmia and neurasthenia, and both Graves's disease and interstitial nephritis were suspected. About six months before coming under observation she had a convulsion with loss of consciousness, this being followed by several others of a similar kind.

The patient was having at somewhat frequent intervals attacks beginning with pain in the head, which was referred to the forehead and eyes. In these she became nauseated and then vomited, becoming pale or even cyanosed, with loss of consciousness. The vomiting was preceded or accompanied by marked facial monospasm, in which the mouth was drawn forcibly to the left and the eyelids were drawn together. Only the left side of the face was involved in the seizure. Examination showed that she had no ataxia of station or gait. Hearing on the right side was good, on the left side it was abolished. The mouth deviated slightly to the left when opened widely. Hypæsthesia to pain was present on the left side of the face and head, and sometimes appeared to be present in the left hand. The patient was not mentally impaired, but was easily exhausted mentally, and was at times irritable and depressed as the result of her sufferings. During the time she was under observation she had frequently recurring headaches, usually severe, sometimes accompanied with nausea or even vomiting, and sometimes with the facial spasm already described. Irregular nystagmoid movements occurred when the patient turned the eyeballs to the extreme right or left. She had complete loss of smell, and loss of taste on the left side of the tongue. On one occasion it was thought that the facial spasm was accompanied by some spasmodic movements of the left hand, but this was doubtful, and even the observer thought it may have been a voluntary movement.

The question of the existence of exophthalmic goitre was one which arose for diagnostic discussion several times during the history of this case. The diagnosis of this affection was first made a year or two before coming under our observation. It was also considered and favorably regarded by some of those who saw her in consultation late in the case. Her eyes had somewhat the staring expression of the blind; they were rather large, but her relatives stated that she had always had prominent eyes, and the exophthalmos was apparent rather than real. The enlargement of the thyroid was so doubtful as to cause some disagreement among those who examined her as to its existence. A slight enlargement of the gland on one side seemed sometimes to be present. Her pulse frequently, perhaps usually, was between 100 and 110, and sometimes rose above the latter point. It was a pulse such as is not infrequently seen in the late stages of an exhaustive intracranial disease. Graves's disease was finally excluded. In the light of the post mortem findings, it is not improbable that some of the symptoms simulating this affection were due to the tumor, from its position, causing vasomotor and cardiac disturbances.

Ocular and ophthalmoscopic examinations were made by Dr. W. C. Posey, who reported as follows: Ocular movements good in all directions, except externally to the right, where there is a slight limitation of movement, the right eye not being brought as far as normal into the external canthus. On fixation in the median line, and below, the eyeballs are quiet. Marked lat-

eral nystagmic movements appear, however, as soon as the eyes leave these primary positions, the nystagmus being most marked on extreme outward rotation to the right and to the left. The pupil in the right eye is round, and is 5 mm. in size; that in the left eye is oval, 3 by 4 mm., with its long axis at 50°. The irides do not respond to light or accommodation stimuli. The ophthalmoscopic examination reveals clear media in each eye, with the signs of regressive optic neuritis. The swelling of the nerves, however, is still very marked, both papillæ projecting into the fundi to the extent of 2 or 3 mm. The nerves are gray and succulent looking, and the retinal arteries and veins are tortuous and cord like. One nerve is not more swollen than the other. There are no extravasations or hæmorrhages, or traces of either of these in the fundi. The patient is totally blind.

Other examinations were made by Dr. Posey, but they did not demonstrate anything different from what is above recorded.

Eventually an operation was performed in this case by Dr. W. W. Keen, by whom the patient was seen in consultation with Dr. Mills. Although a tumor at the base was considered, it was thought for several reasons that lesion was probably in or beneath the facial centre. In the first place sufficient consideration was not given to the tinnitus and deafness. Owing to the fact that a peripheral operation had been performed early for the relief of the latter, it was supposed that the impairment and disturbance of hearing were due to causes which were at least in part peripheral. The facial monospasm was much like that which is observed in the case of subcortical or cortical growth. It is interesting to note that some disease of the cortex was present at the position of the trephining, as demonstrated at the necropsy, but no tumor was found here. The patient died a few hours after the operation.

THE DIAGNOSIS OF TUMORS OF THE CEREBELLUM AND THE CEREBELLOPONTILE ANGLE, ESPECIALLY WITH REFERENCE TO THEIR SURGICAL REMOVAL.

By CHARLES K. MILLS, M. D.,

PHILADELPHIA,

PROFESSOR OF NEUROLOGY IN THE UNIVERSITY OF PENNSYLVANIA; NEUROLOGIST TO THE PHILADELPHIA HOSPITAL.

(Concluded from page 270.)

CASES ILLUSTRATING PAPERS OF DR. MILLS AND DR. FRAZIER.

CASE I.—Tumor of the left lateral lobe of the cerebellum; operation; recovery.

L. P., white, single, aged twenty-three years, was admitted to the Hospital of the University of Pennsylvania December 7, 1903. Her family history was negative. She was strong and well until the beginning of the illness, which brought her to the hospital.

In February, 1903, she began to have severe headaches with attacks characterized by vertigo, especially when standing and walking, but occasionally when lying down. She also at times early in the attack had a series of visual and ocular phenomena, including temporary hemianopsia; scotoma either early or late; light flashes sometimes lasting throughout an attack; subjective images, especially about the time of her coming to the hospital, when she saw dogs, cats, mice, bugs, spiders, etc.; and diplopia in which one image would be in advance of the other, this being especially constant in the left eye. Nausea preceded, accompanied, or came on late in the attack. Vomiting generally appeared late in the attack and gave the patient some relief.

Her headache was located in the forehead or at the base, or more commonly in both regions at the same time. From February, 1903, to September, 1903, the patient had suffered from these attacks once every five days, with the exception of two weeks in July. About the middle of August, 1903, and in October, 1903, her gait became staggering. During the latter part of November up to the time of admission to the hospital she had been unable to walk more than a few steps without support. Since August, 1903, the headaches had been more or less constant. On admission to the hospital she complained especially of nausea and of severe frontal headache, of pain in the back of her head and neck, and in her back. This patient was admitted to the University Hospital under the care of Dr. J. D. Steele, and was later transferred to the service of Dr. Mills. Careful examinations were made by Dr. Steele, but with negative results, except as regards her nervous system, and the existence of patches of brown

pigmentation over the entire body. Examinations of both urine and blood were negative.

Later repeated examinations were made by Dr. Mills and also by Dr. Spiller in consultation. The results of these examinations can be summarized, as but little change took place until the time of operation, except for the worse as regards particular symptoms, like optic neuritis, headache, nausea, and ataxia. The patient exhibited marked ataxia of station. The incoordination in standing was usually not increased by closing the eyes. Numerous examinations showed a tendency of the patient to deviate, pitch, or fall to the left in standing and walking; exceptionally the tendency was in the other direction. Testing the extremities separately, fairly marked ataxia was present on the left, and to a slighter extent on the right. On several examinations the patient showed distinct asynergia in the left lower extremity. The symptom was not, however, uniformly present, and on at least one occasion some asynergia seemed to be present in the right. The Babinski response was present on the right; both knee jerks were absent and the tendon and muscle jerks in the upper and lower extremities were generally depressed. Apparently the movements of both external straight muscles were at times impaired, although the report of Dr. de Schweinitz showed abducens weakness only on the left. On the negative side nystagmus was absent, as were also involvement of the fifth, seventh, or other cranial nerves, and of disturbances of sensation. The patient continued to suffer greatly from headache, vertigo, nausea, and vomiting, the optic neuritis increasing and becoming of the highest grade.

Eye examinations were made by Dr. G. E. de Schweinitz, who reported as follows: December 8, 1903, the vision of each eye equals hand movements. The pupils react sluggishly to light and convergence. There is a history of diplopia and there probably is paresis of the left external rectus, but the double images cannot be elicited, and this is inferred only from the failure of rotation in the line of the direction of the action of the left externus. The ophthalmoscope reveals the following conditions: in the right eye there is a high grade of papillitis (choked disc), the apex of the swelling being 7 D. It is intensely injected, and the sloping margins of the elevation are thickly infiltrated with hæmorrhages. In the left eye there is an exactly similar condition, and in addition a typical macular figure resembling that seen in albuminuric retinitis. Careful testing of the visual field indicates that while it is contracted there is no hemianopic defect.

December 17, 1903, Dr. Frazier operated. An incision was made, following and a little above the superior curved line from the mastoid process to the occipital protuberance, and thence downwards in the median line for a distance of 4 cm. The opening in the skull was made with the chisel and enlarged with the rongeur forceps. The dura was normal in appearance and seemed thinner than usual, and seemed unusually tense. A dural flap was reflected and the surface of the hemisphere inspected. Failing to determine the

presence of a tumor by the sense of sight or touch, an incision was made in the left cerebellar hemisphere, which revealed a small encapsulated tumor of about the size of a hazelnut; the tumor was easily shelled out. The protrusion of the cerebellar tissue was so great that it was necessary to remove, in addition, about one fourth of the cerebellar hemisphere in order to be able to close the dural wound. The patient reacted promptly from the operation, and convalescence was uninterrupted.

The following reports were made by Dr. de Schweinitz after the operation:

December 20, 1903.—The changes evident to the ophthalmoscope are almost exactly those which have been recorded, with the exception of some fresh hæmorrhages which have appeared on the nasal halves of the swollen nerve heads.

January 4, 1904.—The ophthalmoscopic appearances noted by Dr. Shumway are double optic neuritis, plus 6 D. The vision of the right eye is doubtful light perception. The left eye is absolutely blind. A repetition of his examination on the following day by Dr. de Schweinitz confirmed the observations. No changes were noted at the next examination, on the 7th of January.

Examination, January 17, 1904.—There is marked subsidence of the swelling of the discs, the apices of which are not more than 3 D., and the edges of the disc margins are beginning to appear. The macular figure noted before is very marked, and is now evident in both eyes. The retinal vessels are beginning to shrink and atrophy is rapidly supervening. There is no light perception. This examination was repeated on January 25th, with practically the same results, possibly still further diminution of the swelling of the discs. Some weeks later, after the patient was dismissed from the hospital, the ordinary signs of postneuritic atrophy were present. The eyes were divergent, the pupils large and not responding to light.

This patient who presented the typical symptoms of a tumor involving in large part one lateral lobe of the cerebellum, and therefore one of the most desirable cases for operation, was greatly benefited so far as the focal symptoms of a cerebellar tumor and the general symptoms of an intracranial growth were concerned. Her headache, nausea, vomiting, and vertigo disappeared in spite of her almost total blindness; her ataxia was also almost entirely relieved. The optic neuritis had advanced to such a degree, even before she was admitted to the hospital, that operation did not save her from blindness, although surgical procedure was adopted about ten days from the time of her admission.

CASE II.—Tumor of left lateral lobe of the cerebellum; operation; recovery; relapse.

F. M., ten years old, was referred to the University Hospital by Dr. D. J. McCarthy, with a diagnosis of tumor of the cerebellum, and was admitted to the wards of Dr. Frazier, March 7, 1904. After admission to the hospital he was seen in consultation by Dr. William G. Spiller and also by Dr. Mills.

One point of interest in the family history was

the fact that one brother of the patient had some pulmonary disease, chronic in character. The patient, up to the time of his present illness, had been a healthy child, had gone to school at the age of six years, and had been able to keep up with his classmates.

Toward the end of December, 1903, the mother noticed that the boy was not as lively as before, and that he stayed in the house in preference to going out of doors. She took him to the Episcopal Hospital, where he was treated for a cough. At this time he had lost some weight and was generally run down in health. After treatment he improved, gaining weight, but he was unsteady in walking.

About the middle of January, 1904, the boy began to suffer from severe headaches, apparently causeless, these being accompanied by vertigo. At this time the patient held his head up straight and avoided stooping, fearing increased dizziness. During two or three weeks vomiting had been added to his other symptoms, this occurring two or three times a week. Evacuation of the contents of the stomach did not bring relief.

At about the time of his admission it was noted that he had not had any convulsions, that his hearing was unaffected, that he had not complained of interference with vision, that a gradually increasing ataxia was present, and also that his headache, vertigo, and vomiting were augmenting.

The analysis of his urine showed no albumin, casts, or sugar, and a specific gravity of 1.018, the examination being practically negative.

Examination showed that his mental state was distinctly that of lassitude; he was drowsy, took little notice of his surroundings, and manifested when examined, a degree of impatience which was almost irritation. General physical examination of heart, stomach, and other viscera showed nothing of special importance, except of the lungs as given below.

The respiratory excursions were of fair amplitude, apparently equal on both sides. The percussion note showed an impairment over the left apex down to the third rib. Over this area faint crepitant râles were heard on inspiration. Expiration was prolonged, somewhat blowing. Fremitus, both local and tactile, were slightly increased. Various examinations showed ataxia, this present to some extent in the upper extremities as well as markedly present in the lower. No Romberg sign was noted. The examination by Dr. Spiller given below covers, however, the important points in his neurological symptomatology. His pupils were dilated and there was a suggestion of photophobia.

The patient complained of severe headache, locating the pain in the frontoparietal region. Tapping with the finger elicited pain all over the head, this being especially marked over the temporo-parietal portion on the left. No scars or other evidences of injury were discovered.

Shortly after admission while suffering from severe headache, the patient's pulse became exceedingly irregular, both as to volume and rhythm, and its rate was greatly decreased and weakened.

Eye examination of the patient was made by Dr. G. E. de Schweinitz and Dr. John T. Carpenter. The examination made March 8th showed the following: V. of O. D. $\frac{6}{75}$, of O. S. $\frac{6}{75}$. The amplitude of accommodation of each eye is 12 D. The pupils are round and the irides react promptly to light and accommodation and convergence. With the exception of a slight esophoria, there is no defect of muscle balance and no diplopia. The ophthalmoscope reveals the following conditions: Right eye papillitis (choked disc), the apex of the swelling being 4 D., the vessels on the surface of the disc $1\frac{1}{2}$ D. higher. The nerve edges are entirely obscured. The surrounding retina is not involved. In the left eye there is an exactly similar swelling of the disc, with the exception that its nasal edge is more involved. There is a moderate concentric contraction of each visual field, more marked upon the left than upon the right side.

Examination by Dr. Spiller on March 9th showed the following: The tenderness of the scalp to percussion formerly noted had disappeared. He held his head retracted, because he said it caused him pain to hold it straight. There was no distinct rigidity of his neck; movements of the head were free in all directions; passive movements caused headache. The movements of the eyeball were free in all directions; some nystagmoid movements were present when looking to the extreme right or left. The fifth and seventh nerves were not involved on either side. The tongue showed a slight tendency to deviate to the right when protruded; no distinct fibrillary tremors of the tongue were noted.

The grasp of each hand was fair and equal on both sides. The finger to nose test did not reveal distinct ataxia. The upper limbs were slightly but not distinctly atrophied. The biceps, triceps, and wrist reflexes were not distinct on either side. The voluntary movements of the upper limbs were normal. There was no loss of sensation to touch or pain. The muscles of the trunk were fairly well developed.

The voluntary movements of the lower limbs showed normal muscular power and no wasting. The patellar reflex was lost on both sides; even when sitting on the edge of the bed with reinforcement there was no response. The Achilles jerk was not present on either side; the Babinski reflex could not be obtained on either side; there was no ankle clonus. The heel to knee test did not reveal ataxia. Sensation for touch and pain was normal. At the time of this examination the gait was not ataxic with eyes open; it was slightly so when the eyes were closed. There was no sway when standing erect, either with the eyes open or closed. No hemiasynergia was present on either side; Koenig's sign was also absent on both sides. The operation was performed by Dr. Frazier on March 13, 1904. The bone overlying the left lobe of the cerebellum was very thin and the dura was unusually tense. Immediately after the dura was opened the hemisphere protruded to a much greater degree than usual. No adhesions were found either between the skull and dura or between the dura and cerebellum. The latter did not pulsate. A thorough exploration of the left

hemisphere failed to reveal the presence of a tumor. As a palliative procedure one third of the cerebellar hemisphere was removed. The patient's condition immediately after the operation caused some anxiety, but after intravenous injection and mild stimulation the patient improved rapidly and spent a comfortable night. The wound healed by first intention. On March 27th the patient's condition was noted as being greatly improved. His whole disposition had changed; he was bright and cheerful and complained neither of headache nor vomiting.

In November, 1904, the patient returned to the hospital, because of recurrence of some of the symptoms. On the following day an incision was made, following the line of the old cicatrix, and an infiltrating tumor of about the size of a walnut was found in the hemisphere, apparently taking its origin from some point near the cerebellopontile angle. The patient reacted promptly after the operation, the wound healed by first intention throughout, and convalescence was uninterrupted. The tumor was a glioma. After the notes of the case were sent to the press the patient relapsed, showing that the growth was probably infiltrating and had not been fully removed.

Eye examination made after the operation by Dr. G. E. de Schweinitz and Dr. J. T. Carpenter, March 14th. The condition of the right disc is unchanged. On the left side there has been a subsidence of the swelling, which is now 3 D. in place of 4 or 4½ D.

CASE III.—Tumor of the cerebellum, probably of the vermis and left lateral lobe; operation; tumor not found; recovery from operation, with relief of symptoms.

J. H., forty-one years old, was admitted to the University Hospital March 6, 1902, under the care of Dr. Mills and Dr. Frazier. No history of nervous or tuberculous disease or of tumor could be ascertained, but an aunt had suffered from cancer of the face, probably dying from this affection. The patient denied syphilis.

About two years before admission to the hospital he began to have headache, most marked behind the eyes and in the temporal regions. His sight also began to fail at this time, and his gait became unsteady, he tending to totter or fall to the right side. His headache improved under treatment, but his sight and gait remained the same.

In May, 1901, he had a crisis of vomiting, which lasted for about a week; he vomited almost daily, immediately after eating, there being little retching or straining accompanying the vomiting. The left leg at this time seemed weaker than the right. His bowels were constipated, and were moved by laxatives daily for two years before he came to the hospital. He had no pain in the anus or in the legs. He was not paralyzed and had no vesical symptoms. There was no history of vertigo; his hearing was not disturbed and his memory was good. On rising in the morning he had on a few occasions attacks of faintness or weakness, but he had never lost consciousness.

Examination of the urine two days after admission to the hospital was negative.

Several examinations of this patient, made by Dr. Mills and Dr. Spiller shortly after admission, gave the following results: Vertical nystagmus was present when the eyes were at rest or when they looked upward or downward, the nystagmus becoming lateral when the eyes were turned to the right or left. The patient in walking took short, unequal steps, showing a lack of confidence; at times he exhibited a tendency to go to the right. In standing the feet were kept wide apart, as he swayed greatly and would have fallen if not supported when the feet were together. The sway was not distinctly increased by closure of the eyes. Ataxia was present in the left upper extremity, and doubtfully in the right. Speech and mental response were both slow. The tongue was protruded straight and without fibrillary tremor. The knee jerks were prompt, the left distinctly exaggerated. The Achilles jerk was present on each side. Ankle clonus was not present on the right, but was slightly indicated on the left. The Babinski reflex was not present on either side, the movement of the toes being that of slight flexion on both sides.

An eye-examination was made by Dr. Howard Mellor, March 7th, the date of his admission. Visual acuity and the amplitude of accommodation were not recorded. He reported the following: The pupils are equal in size and the irides react promptly to light and in convergence. The ophthalmoscope reveals the following conditions: A low grade neuritis with involvement of the surrounding retina (neuroretinitis), which is most marked in the left eye. There is very distinct vertical nystagmus when the patient looks directly forward, and extremely marked lateral nystagmus on looking to either side. When the gaze is directed upwards or downwards, the vertical nystagmus increases. The rotations of the eyeballs are normal in all directions.

The patient left the hospital and was readmitted on October 9, 1902. His difficulty in walking had gradually increased until he was able to walk only a few steps with a cane, and at times he fell. When assisted he walked by raising the leg and foot high, and bringing it down heavily. His feet were always wide apart. Ataxia was marked. He had not vomited since leaving the hospital. The nystagmus was the same as on the first admission. A twitch of the orbicular muscle in the left eye was noticeable at times. He could hear a watch at three feet, on the right side, on the left he could hear it at a distance of two inches. He had no tinnitus or other abnormal sounds. He complained of no trouble with the bladder or rectum. He had no astereognosis.

Examination by Dr. de Schweinitz, October 9, 1902.—V. of O. D. $\frac{1}{22}$, of O. S. $\frac{1}{22}$. The patient reads J. 2 at 33 cm. with each eye. The pupils are equal and respond promptly to light and convergence. The nystagmus recorded in the previous examination continues unchanged. The ophthalmoscope reveals the following conditions: The right optic nerve is beginning to be atrophic, the vessels being reduced in calibre, and there is an area of atrophy of the chorioid surrounding the nerve head. In the left eye a moderate neuritis with indications of beginning atrophy is evident.

No atrophy, rigidity, contractures, or spasticity was present in the lower extremities on either side. Late in the case the muscles of mastication were normal on the right, and distinctly weak, although not paralyzed fully, on the left. When the mouth was opened the jaw tended to go slightly toward the left. Sensation was unimpaired everywhere. No hemiasynergia was present on either side.

The prominent symptoms in this case just before the operation were secondary optic atrophy, headache and vomiting, nystagmus, cerebellar gait, exaggerated reflexes, deafness on the left side, weakness of the left motor fifth, and probably some weakness of the soft palate on the left side.

October 25, 1902, the patient was operated upon by Dr. Frazier. Upon the left side of the head a horseshoe-shaped flap was reflected, the incision beginning at the tip of the mastoid process following the superior curved line, and terminating in the median line of the neck, opposite the spinous process of the second cervical vertebra. The skull was opened as usual with a chisel and mallet, and the opening enlarged with a rongeur forceps. There was an escape of a moderate amount of cerebrospinal fluid. Inspection and palpation of the cerebellar hemisphere revealed no abnormality. There was no thickening of the meninges, no alteration in color or consistency of the cerebellar tissue. It was deemed inadvisable to make any further inspection and the wound was closed. The patient recovered from the effects of the operation, and declined any other intervention, although Dr. Mills and Dr. Frazier advised an exploratory operation upon the opposite side.

CASE IV.—Tumor of the cerebellum or cerebellopontile angle; tumor not found, but lateral lobe partly excised with great benefit.

G. E., twenty-three years of age, was referred to Dr. Mills for opinion and treatment. When the patient presented himself to the hospital he was suffering from most distressing headache, which was almost constant, and from vertigo and ataxia, to such an extent that it was impossible for him to walk alone or without support. Nor could he even stand alone, unless leaning against some stationary object. His vision was so affected that he could not see gross objects, and examination of his eye grounds revealed the presence of very marked choked discs and optic neuritis.

The patient was suffering to such an extent that it did not seem justifiable to postpone operation for further and more elaborate study of the case. Accordingly within a week of his admission to the hospital a left cerebellar craniectomy was performed by Dr. Frazier. The dura was noted to be unusually tense, and upon reflecting the dural flap a considerable portion of the cerebellar hemisphere protruded through the opening. It was found to be almost impossible on account of the protrusion of cerebellar tissue to make further exploration, so the operator proceeded to remove from one third to one half of

the lateral lobe. After this was accomplished exploration was continued, but to no avail. No tumor could be seen or be felt in any portion of the left cerebellar fossa. The postoperative record of this patient is one of unusual interest, because of the remarkably rapid improvement which followed. Within one week of the operation the patient's headache had entirely disappeared, his vision was restored so that he could see minute objects on the ceiling as he lay in bed, and his vertigo and ataxia had almost entirely disappeared. At no time during the convalescing period was the patient's condition such as to give any concern. He was kept under observation in the hospital for a period of two months, and inasmuch as there was not the slightest return of symptoms he was allowed to go home with the understanding that he would return to the hospital if any of his cerebellar symptoms recurred.

CASE V.—Tumor probably of the cerebellum involving the vermis and right lateral lobe; operation in two stages planned; death from hemorrhage from bony sinuses twelve hours after first operation.

J. C., fifteen years old, was referred by Dr. Samuel Freeman and Dr. Frank V. Cantwell, of Trenton, N. J., to Dr. Mills for opinion and treatment. He had a history that fifteen months before coming under observation he had begun to suffer with headache, this having been preceded by dizziness; he also began to suffer from vomiting six months before, and exhibited a staggering gait one month later. The attacks of headache, dizziness and nausea and vomiting increased in frequency and in severity, and the uncertainty of gait became steadily more and more marked.

When the patient was first examined it was found that he was suffering intensely from headache, which was almost continuous, while his dizziness, nausea, and vomiting were of frequent occurrence.

The eye examination made by Dr. G. E. de Schweinitz, July 5, 1904, resulted as follows: V. of O. D. $\frac{4}{8}$, of O. S. $\frac{4}{8}$. Amplitude of accommodation markedly defective, the patient being able to read only D. = 1 at 18 cm. The pupils are large, but their reactions are normal. There is paresis of the left external rectus muscle, and lateral nystagmus develops, when the eyes are directed to the left, that is to say, in *lævo*version. The ophthalmoscope reveals the following conditions: In the right eye papillitis, the apex of the swelling being 3 D. It is vascular in the extreme, but the centre of the disc is not markedly filled in. The veins are full and carry very dark-colored blood. There is no macular figure. In the left eye the papillitis is greater than on the opposite side, the apex of the swelling being 5 D. with decided engorgement, and the appearance to which the name choked disc is ordinarily given. The veins are even fuller and darker than upon the other side. The peripheral visual field for form of each eye is normal. There are no scotomas.

Comment.—The double optic neuritis (choked disc), together with paresis of the left external

rectus muscle and lateral nystagmus, especially when the eyes are directed towards the left, are ocular signs frequently seen in cerebellar diseases.

At one examination it was noted that in standing or walking the patient was markedly ataxic and asthenic, always tending to the right, and that ataxia, less marked, was present also in the upper extremities as determined by having him touch his nose with the finger and in other ways. This ataxia was doubtfully more marked on the right. Hemiasynergia was not present.

His mental condition was good, except in so far as he was irritated, depressed and worried by the pain.

His muscles were flaccid and atonic. There was no distinct paralysis of the extremities, but his head showed some tendency to drop backwards, especially when he would look upward. This was probably due to weakness of the supporting muscles of the neck.

At a second examination a few days later it was noticed that he swayed markedly to the right, standing with eyes shut and considerably with eyes open. He invariably staggered or tended to the right in walking, his gait being somewhat titubating. There was some ataxia in both arms, possibly a little more on the right. No hemiasynergia was present. Tremor was marked in both upper extremities, a little more so on the left; it was coarse, jerky and increased by action. The muscular sense was preserved, as was also stereognostic perception. The right side of the face was apparently hypæsthetic, as were also the arm and leg of the same side. This symptom, however, seemed variable or doubtful, as the patient did not always answer in the same way as regards the impression made. The head was not carried towards either shoulder, but, as stated above, sometimes it had a tendency to droop or fall backwards. Both knee jerks were plus. The Babinski response was absent on each side. Incontinence of urine or feces was not present.

Paresis of the left external rectus, with nystagmoid movements when the eyes are turned far to the left, was present; no such movements were shown when the head was turned to the right upwards or downwards. When the patient followed the finger with his eyeballs von Graefe's sign was very distinct. About $\frac{1}{8}$ inch and possibly even more of the white of the eyeball was seen between the iris and the upper lid on each side.

The knee jerks were slightly plus; the ankle jerks about normal; the muscle jerks a little below normal. The tongue was protruded straight and was not atrophied. It exhibited no fibrillary tremor.

Speech was a little peculiar, but the patient said that it had always been the same as it was at this time.

According to Dr. B. A. Randall's report, the patient had nearly normal ears in appearance and function with possibly a trace of tympanic reduction of hearing; the auditory nerves seemed to be in perfect condition.

There was no thyroid or other glandular enlargement of the neck. The thorax was small, narrow, and poorly shaped and developed; the supraclavicular and infraclavicular spaces were prominent; the expansion was poor. In front and back of the lungs the breath sounds were clear but faint. The action of the heart was regular; there were no murmurs. The abdomen was flat.

The patient came under observation July 6, 1904, and was admitted the same day to the University Hospital, where he was seen by Dr. Spiller in consultation with Dr. Mills. The diagnosis of tumor of the cerebellum probably involving the right lateral lobe, was made.

The operation was performed by Dr. Frazier July 9, 1904, with the object of exposing the right lateral lobe of the cerebellum. The usual incision was made and the skull opened in the customary way. Upon reflection of the musculocutaneous flap, two large anomalous sinuses were exposed, making their exit at a point about 2 cm. from the occipital protuberance and a little below the superior curved line. The blood poured out from these sinuses in great quantities, and every attempt which was made to control the hemorrhage by pressure, Horsley's wax, etc., failed, until some small plugs of wood, made from swab sticks, were driven into the bone. By this time the patient had lost considerable amount of blood, and was evidently suffering from its effect. Stimulation was resorted to; a hypodermic of strychnine was given and a pint of 1 to 50,000 adrenalin salt solution was administered intravenously. By this time the blood pressure had fallen to 55, and for the next fifteen minutes remained at 50. It then fell to a point too low to estimate, and another pint of 1 to 50,000 adrenalin salt solution was given intravenously. In twenty-five minutes the blood pressure rose to 100, and the adrenalin was discontinued. The blood pressure began to fall again and resort was had again to intravenous injections of adrenalin. Owing to the excessive hemorrhage it was decided to postpone the actual exploration for the tumor until the patient had fully reacted. The operation was performed at 2 p. m., and from that on to 1 a. m. on the following morning the patient's condition gradually improved. At 1 a. m. his pulse was only 96 and of fair volume. His color good and his respirations were 15. At 1.15 a. m. his pulse was 98, and his respirations were 14. At 1.30 a. m. his condition was reported as unchanged, with the exception that his respirations had dropped to 11. At 1.40 a. m., without any warning, the pulse suddenly shot up to 120, respirations dropped to four. The patient became cyanotic and died at 1.45 a. m. No autopsy was permitted.

It is difficult to account for the death of this patient. One can hardly attribute it to the excessive hemorrhage at the time of the operation, although this may have been a contributory cause. The condition of the pulse and blood pressure showed that the patient had almost fully reacted soon after the operation. The slow respiratory rate suggests the possibility of an in-

jury to the respiratory centre, although this would hardly have been inflicted by any step in the operation, inasmuch as no attempt was made to explore the cerebellar fossa.

CASE VI.—Cerebellopontile operation for tumor of pons; probable second lesion in parietal lobe; cyst evacuated; permanent disappearance of severe headache and facial neuralgia.

This patient, a woman, about forty-five years old, first came under the care of Dr. Mills in November, 1902. One year before coming under observation she had an attack of vertigo without unconsciousness and after this partial paralysis of the left third nerve was observed, ptosis, dilated pupil and paresis of the internal rectus being present, according to the physician then in attendance. She also appeared from the history to have had temporary paralysis of the left side of the face. She had subsequent similar attacks, some of these shortly before coming under observation. In one of the recent seizures she was found in the cellar, pacing up and down with her hands above her head, eyes dilated and apparently struggling against suffocation. She was taken upstairs and put to bed; she tried to speak, moving her jaws without uttering any sound; her face was pale, her eyes were open. At the time of the first examinations she had paresis of the left side of the face, partial ptosis, pupils equal and responsive, the superior rectus not being as active on the left side as on the right.

In the fall of 1902 the patient was under the care of Dr. Mills in a private hospital. During this period her chief symptoms were occasional headache, general nervousness, and at times slight mental confusion. The partial palsies of the third and seventh nerves as above noted were present.

In the summer of 1903 she went to a mountain resort, and while there she had an attack of convulsions, after which she had partial paralysis in the right half of the body. The physician called in to see the patient because of the attack of spasm, wrote to me as follows regarding his observations:

"When I saw the patient she was in a semi-comatose state, and from superficial observation and the history given I thought that I had a hysterical condition. A dose of potassium bromide aroused her from the stupor following the convulsions, which, with the stupor, had lasted eight or ten hours. The spasms had not been especially pronounced, and had subsided some three hours previous, with the exception of some twitching around the mouth. From the account given, the contractions were alike on each side, and at the time of my visit no paralysis was present, although it was stated that at some previous time she had had left-sided paralysis, but not in this attack. Mentally she was unbalanced. She seemed to grasp the purport of a question, but generally gave meaningless answers. She was hunting for some imaginary thing which she had lost, and every moment or two earnestly asked the time of day. On attempting to arise in the morning, she fell from the bed, prone, evidently the commencement of

her convulsive attack. Inquiry elicited the fact that there had been some previous brain lesion, which I could not definitely locate, but the knowledge of which, with the other symptoms, excluded the idea of hysteria."

When seen shortly after this, in addition to the symptoms already noted, she also showed some amnesia for names, and some mental change or weakening hard to describe and complained much of headache. Ophthalmoscopic examination made about this time by Dr. S. D. Risley showed no optic neuritis, but bad eye grounds, probably due to eye strain.

An eye examination was made by Dr. G. E. de Schweinitz on September 10, 1903, who reported as follows: V. of O. D. $\frac{5}{6}$, of O. S. $\frac{5}{6}$. Amplitude of accommodation, 4 D. The pupils are round and react normally to light, accommodation and convergence. There is slight ptosis of the left eye and paralysis of the left inferior rectus muscle. The ophthalmoscope reveals the following conditions: Both optic nerves are round, their nasal and upper edges being veiled. The central lymph sheaths are fuller than normal and the veins somewhat overdilated. This is particularly true of the lower temporal vein of the left side. The veiling of the disc edges is evident, as well by indirect as by direct method of ophthalmoscopy, and taken into consideration with the overcapillarity of the disc surface, may be regarded as indicating a congestion of the nerve heads. Actual neuritis is not present, as there is no swelling of the papillæ. The visual fields are normal.

The patient was examined by Dr. Mills, Dr. Dercum, and Dr. Spiller in consultation on September 11, 1903. Resistance to passive movements in the lower limbs was about equal. Knee jerks were much exaggerated on both sides; ankle clonus was easily obtained and persistent on the right; it was faint and not persistent on the left. Her station was erect and normal with eyes open. She swayed distinctly with eyes closed, the sway being greater towards the right. Her gait was a little uncertain, much more so with the eyes closed. She showed a slight tendency to drag the right foot as if it stuck to the floor. In walking backward with her eyes closed she put the left foot backward and drew the right foot to it. The Babinski reflex was doubtfully present on the right side, but was not obtained at all on the left, the toes responding by plantar flexion. When a pencil was laid lengthwise or crosswise on either foot she was unable to give the correct position; the position seemed to her usually as being across the toes. Touch was felt everywhere, but distinctly better in the upper and lower limbs on the left side and on the left side of the face than in the corresponding parts of the right side. Pain stimulus was felt everywhere, but like tactile sensation was more distinct in the left upper and lower limbs and left side of the face. Sensation for cold and heat was everywhere normal.

The grasp of the right hand was distinctly weaker than that of the left. The fingers of the right hand were kept partially flexed at the junc-

tion of the second and third phalanx, the thumb extended. She could fully extend the fingers, with the exception of the middle one. Apposing the thumb to the little finger on the right hand was very difficult. Triceps tendon jerks and wrist reflexes were exaggerated on each side, distinctly more so on the right than on the left. The palm of the right hand was a little puffy, but not distinctly cedematous. She could raise the right upper limb to the full extent above the head; resistance to passive movements was much impaired in the right upper limb. She experienced difficulty in placing the first finger of the right hand on the nose, usually carrying it to one side of the nose. She was uncertain as to the position of her little finger when it was raised, usually saying it was the ring finger; she knew the other fingers on the right hand when they were raised. Stereognostic perception was greatly impaired on the right hand and not on the left. She could not, for instance, recognize a knife, pencil, or other object in the right hand, but recognized them promptly in the left. The sense of position of the toes of both the right and the left foot seemed to be preserved. She exhibited a slight weakness in drawing up the right corner of her mouth, but drew the left side up better. She closed her eyelids firmly on each side, and wrinkled her forehead well and equally on the two sides. The tongue was protruded straight and showed fibrillary tremor. She said that her tongue had felt numb and stiff for two days before the examination. The masseters and temporals contracted firmly on each side. She heard a low ticking watch only when it approached to within about two inches of either ear, the hearing seeming to be the same in each ear. Sugar and salt were tasted promptly on each side of the tongue.

Dr. J. W. McConnell examined the patient on September 12, 1903, and reported that subsequent to the above examination she had an attack of twitching of the right arm and the right leg with unconsciousness. There were no changes from the examination of the previous day. She complained of intense pain in the left parietal region, and also said that she had some numbness in the left arm and leg.

After this she was seen from time to time by Dr. Mills, and on several occasions for him by Dr. T. H. Weisenburg, who made a few notes as follows: September 14, 1903. Paresis of the left internal rectus was present. Astereognosis was not present in the right hand, and the sense of position of the right hand was normal.

September 16, 1903.—She had a left-sided peripheral facial palsy, also a paresis of the left external rectus and of the internal rectus. No sensory changes were present on the left side.

The patient was again examined by Dr. Mills and Dr. Spiller on September 22, 1903. The left side of the face was paralyzed in the entire distribution of the seventh nerve. She complained of much pain, confined to the left side of the face and in the distribution of the fifth nerve. The masseter and temporal muscles contracted well in chewing on each side. No distinct objective disturbance of sensation on the left side of the

face was made out. The left external rectus seemed to be the only external ocular muscle distinctly paretic. Astereognosis in the right hand was almost complete.

She complained of much pain on both sides of the forehead, extending down the left side of the face to the lower border of the lower jaw. The pain did not extend below the median line of the lower jaw; it extended to the mastoid process, but not beyond this on the left side; it did not extend into the neck. She had constant pain in both temples, but it was greater in the left than in the right. All points of exit of the fifth nerve were painful to pressure; as much so on the right side as on the left. Sensation for touch and for pain on the two sides of the face seemed to be normal; she felt a touch or pin prick as well on the left side of the face as on the right. In such instances as when chewing a hard crust of bread, the left masseter contracted, but not so well as the right; in opening the mouth the lower jaw did not deviate distinctly. She complained of a sense of numbness in the left side of the face; this involved the entire distribution of the fifth nerve and extended up on the left to the temple, but not far beyond the border of the hair. There was considerable improvement in the paralysis of the orbicularis palpebrarum. There was complete paralysis in the lower distribution of the left facial nerve. The right side of the face was normal.

She did not have any nausea and seldom had spells of vertigo, although formerly the latter occurred frequently. She showed a tendency at times to fall backwards or towards the left, but did not stagger as much as formerly; closing the eyelids did not affect the gait very distinctly. Hemiasynergia was not present on either side.

As the patient was slowly getting worse and was suffering extremely with pain in her head and face, it was finally decided to remove her to the University Hospital for the purpose of having an operation, which might at least be palliative. Her pain increased until it became torturing, and for days before the operation it was necessary to keep her continuously under the effects of morphine or codeine. No change of any moment occurred in her focal symptoms after the above recorded notes.

The operation was performed by Dr. Frazier on October 14, 1903, under ether anesthesia. A musculocutaneous flap together with the periosteum was reflected and an opening was made in the skull with the chisel and enlarged with Rongeur forceps. Nothing abnormal as regards pulsation nor consistency of the left lateral lobe of the cerebellum was noted. The dural flap was reflected; at one point this flap was adherent to the underlying brain. Cerebellar tissue bulged only moderately through the wound. On exploring with the index finger in the region of the cerebellopontile angle some adhesions were separated on the lateral aspect of the cerebellum. This was followed by a gush of fluid which had evidently been walled off by adhesions. After the evacuation of the cyst the bulging subsided immediately and with a brain retractor it was

possible to inspect the region of the cerebello-pontile angle and to demonstrate to those present at the operation, the fifth, seventh, and eighth cranial nerves. It was noted on the blood pressure chart that when the dura was opened the blood pressure dropped thirty points, and that upon introducing gauze packing or upon compressing the brain with the retractor that the blood pressure rose forty points. The patient's condition was not depressed to any considerable degree by the operation; upon her return to bed her pulse was 145; respirations were 40, and blood pressure was 115.

The interesting feature of the case was the ease with which the cranial nerves were exposed after the cyst had been evacuated.

The patient reacted well after the operation and passed a fairly comfortable night. There was very profuse oozing of blood and cerebrospinal fluid, necessitating frequent reinforcement of dressing. The patient was much nauseated, vomiting curds of milk and bile stained fluid. She complained of pain in her temples. A hurried examination showed that sensation was present on both sides of the face and no inequality of pupil was noted.

On October 15th the wound was dressed; it was found in good condition; the drainage was removed; there was a free flow of cerebrospinal fluid.

An examination by Dr. Mills and Dr. Spiller on this date (October 15th) resulted as follows: No cutaneous anæsthesia was present on either side; not even any hypæsthesia on the left. There was great impairment of the motor division of the fifth nerve, the masseter and pterygoid muscles being tested. Complete paralysis in the muscles supplied by both the upper and lower branches of the seventh nerve was present. She was completely deaf in the left ear. Slight paralysis in the right upper extremity was noticed. Astereognosis or pseudoastereognosis was present in the right hand. Anæsthesia for both touch and pain and hyperæsthesia were absent. She had had no pain in the face or head since the operation, and had required no anodynes.

On October 19th the wound was again dressed and the stitches were removed; the wound was all healed, with the exception of one angle; a small piece of gauze was inserted for drainage. The patient's general condition had been very good. Her pupils were now normal.

On October 24th the surgical condition was entirely satisfactory; the wound was all healed, with the exception of one spot, which was rapidly granulating. The patient's general condition had rapidly improved since last noted. She was regaining strength, had been sitting up and was quite comfortable.

On October 29th the patient was discharged, the surgical condition left nothing to be desired; the wound was completely healed; there was no bulging of the flap, no signs of inflammation or edema of the scalp. The patient had not had any pain in the head or ears; the only discomfort had been some irritation of the conjunctiva of the left eye, which was probably due to facial palsy.

This patient has continued under the observation of Dr. Mills and Dr. Frazier from the time of operation until that of writing (December, 1904). From the time of operation until the present she has not had any pain in the head, although as previously stated, the pain for some time before the operation was of the most intense character. In other respects, her general condition has been good. She still, however, continues to be partially paralyzed with astereognosis and sensory changes on the right side, and still has paralysis in the distribution of the left seventh nerve. It is altogether probable that a lesion of some sort is still present; not improbably she has more than one lesion, as the symptoms point both to the pons and to the left parietal lobe. The case is especially interesting as showing how in some cases the cerebellopontile angle can be exposed and how pain and other symptoms of brain tumor are sometimes relieved even when full success is not obtained.

REMARKS UPON THE SURGICAL ASPECTS OF TUMORS OF THE CEREBELLUM.

By CHARLES H. FRAZIER, M. D.,

PHILADELPHIA,

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF PENNSYLVANIA; SURGEON TO THE UNIVERSITY HOSPITAL.

(Concluded from page 280.)

RESULTS.

To speak first of the results of the cases which have come under the author's observation: During the past twelve months, six patients have been subjected to operation at the University Hospital: five of them were patients of Dr. Mills, and one was a patient of Dr. McCarthy. The records of these cases appear below, but the results may be expressed briefly in the following table:

TABLE I. — CASES UNDER AUTHOR'S OBSERVATION DURING PAST TWELVE MONTHS.

Case 1.	Cranlectomy.	Tumor found and removed.	Recovery.
Case 2.	Cranlectomy.	Tumor found and removed.	Recovery.*
Case 3.	Unilateral cranlectomy.	Tumor not found.	Recovery from operation, without improvement. Patient would not consent to further exploration.
Case 4.	Cranlectomy.	Tumor not found; one-third of hemisphere removed.	Striking improvement. Restoration of vision, relieved of headache, vomiting, and vertigo.
Case 5.	Cranlectomy; 2 stage operation planned.	Dura not opened.	Death, sudden and unaccountable, twelve hours after first stage.
Case 6.	Cranlectomy.	Cyst found and evacuated.	Recovery from operation; great relief of headache and other symptoms.

* Since this writing there has been a recurrence of the growth.

Still further condensed the results were as follows: Of 6 cases: 1 died after first stage of operation; 2 recovered after removal of tumor; 1 relieved

after evacuation of cyst, no recurrence more than a year after operation; 1 considerably improved after palliative operation; 1 no-improvement; tumor not found.

My personal experience with this series of cases leads me to believe that the dangers attending cerebellar operations have been somewhat exaggerated. The present generation of surgeons has inherited the traditional fear of operations within the cranial cavity. It was not very long ago that operations upon the Gasserian ganglion were regarded as desperate undertakings, when it was a case of kill or cure, whereas at the present time the operation is undertaken with no especial concern except upon individuals, who on account of their advanced years might be unfavorable subjects for any major operation. And so it is with tumors of the brain generally and especially with regard to tumors of the cerebellum. Physicians put off the question of operation until the patient's condition becomes critical and the surgeon undertakes the operation with fear and reluctance. It was not so long ago that Oppenheim classed all tumors of the cerebellum as inoperable, but in the last editions of his book (1902) he frankly confesses that his opinion on this point is in need of revision.

The dangers and risk peculiar to this operation lie in the proximity of the medulla and pons to the field of operation and the traumatism to which they may be subjected in the course of the operation. It is on this account that stress has been laid upon the advisability of approaching the cerebellopontile angle from the lateral aspect in order not to injure these structures. In a case of Woolsey's previously referred to, the autopsy revealed a hæmorrhage in the pons which the operator attributed to the traumatism to which it was subjected while he was removing piecemeal a tumor of the auditory nerve. If in the fatal cases a careful examination of pons and medulla had been made we believe that in a majority some evidence of traumatism would have been found. *It is only in the avoidance of every possible source or degree of traumatism to these vital structures that surgeons can hope to obtain better results.* In this connection we refer again to the impunity with which a considerable portion of one cerebellar hemisphere can be removed, since by so doing the operator not only can explore and expose the tumor, but also remove it without the necessity of exerting undue traction or pressure directly or indirectly upon the pons. This of course applies especially to tumors that were not within the hemisphere.

We have been struck especially with the comparatively slight depression attending operations upon the cerebellum and with the rapidity with which reaction ensues. In one of our cases the pa-

tient lost a large quantity of blood in a very short time, but recovered promptly from the effects, after the administration of appropriate remedies. This patient died twelve hours after the operation suddenly and unexpectedly, but ten minutes before he died his general condition was reported as excellent. Our experiences, however, we believe to be exceptional, as there are recorded in literature many cases in which the patients died on the table or a few hours after the operation.

We have noted, however, that the gravity of the operation does not seem to have been affected by the act of removing the tumor; whether the operation was solely exploratory or palliative, or whether a tumor was removed, the effect upon the patient was the same.

STATISTICAL STUDY OF 116 CASES OF OPERATION UPON THE CEREBELLUM, COLLECTED BY FRAZIER.

The following statistics were compiled from the 116 cases of cerebellar tumors found in the appended table, pp. 334 to 337:

	Per cent.
Tumors found.....	45
Tumors not found.....	55
Removal with recovery.....	15
Removal with improvement.....	13.9
Removal without improvement.....	0.9
Improvement without removal.....	13.9
No improvement without removal.....	13.9
Death when tumor was removed.....	12.9
Death when tumor was not found and not removed.....	28.7

A COMPARISON OF THE STATISTICS OF SUCCESSIVE DATES, SHOWING AN INCREASE IN THE PERCENTAGE OF RECOVERIES AND IMPROVEMENTS, AND A REDUCTION IN THE MORTALITY.

Results.	Frazier's table.—1904. Per cent.	Duret's table.—1903. Per cent.	Oppenheim's table.—1902. Per cent.
Recovery	15	14	7.5
Improved	28	25	7.5
Unimproved	15	..	13
Mortality	42	60	71

A COMPARISON OF THE STATISTICS OF TOTAL NUMBER OF CASES IN FRAZIER'S COLLECTION WITH THE STATISTICS OF THE LAST FIVE YEARS, SHOWING A MANIFEST IMPROVEMENT IN THE RESULTS.

Results.	Total number of cases. Per cent.	Cases reported during past five years, 1899—1904. Per cent.
Recovery	15	24
Improved	28	28.5
Unimproved	15	11
Mortality	42	35.8

From a review of these tables one is struck at once with the progress that has been made in this field of surgery from every point of view. The percentage of tumors found is yearly growing larger, the percentage of partial or complete recoveries is larger and the mortality has fallen from 70 per cent. to 38 per cent. We believe that the results of surgical intervention upon the cerebellar hemisphere will continue to improve, if not generally, at least in the hands of those who are giving this subject especial thought and attention.

FRAZIER'S TABLE OF 116 CASES OF CEREBELLAR TUMORS IN WHICH OPERATIVE TREATMENT WAS RESORTED TO.

No.	Authors.	Age, Sex.	Nature and Position of Tumor.	Tumor Found or Not Found.	Results.
1	Albert. <i>Wien. med. Woch.</i> , 1895, No. 1.	39 years. M.	(Autopsy) Endothelioma of tentorium, penetrating left lobe	Not found.	Improvement. Death December 6th.
2	Annandale. <i>Edinburgh Hosp. Rep.</i> , 1895, p. 127.		Sarcoma of right lobe.	Removed	Improvement after two months.
3	Azais. Montpeller thesis, 1900-1901, No. 31.	37 years. M.	Sarcoma in substance on superior aspect.	Not found.	No relief, pain worse; death in two weeks.
4	Beck. Thèse de Paris, 1896, p. 221.	42 years. F.	(Operated on at the age of 27 for tumor of breast.) Carcinoma of pons.	Not found.	Death, third day after operation.
5	Bennett. <i>Lancet</i> , May, 1887, p. 768.	7 years. M.	Tubercle of right lobe.	Removed	Death from shock several hours after.
6	Von Bergmann. <i>Berl. klin. Woch.</i> , 38, p. 219.		Cyst	Removed.	Recovery.
7	V. Bergmann. <i>Deutsche Med.-Zeit.</i> , 1901.	1 years. F.	Cyst under tentorium, arising from gliomatous tumor.	Removed.	Recovery.
8	Devor-Ballance and Lunn. <i>Brain</i> , 1897.		Fibrosarcoma, anterior right cerebellum	Removed.	Recovery.
9	Birdsall. <i>Med. News</i> , 1837.		Spindle cell sarcoma, left side; medulla compressed	Not found.	Death after two months; metastasis into neck.
10	Borelius. <i>Neurol. Centralbl.</i> , 1897, p. 1063.	23 years. M.	Fibroma, size of goose egg in right fossa.	Not found; no distinct local symptoms	Death shortly after operation.
11	Bradford and Knapp. <i>Jour. of Ment. and Nerv. Dis.</i> , 1892, p. 97.	28 years. M.	Glioma of left lobe.	Not found.	Improvement as to headache; death several weeks later.
12	Brewer. <i>Med. News</i> , 1899, 26 years.	M.	Tumor, situated near median line	Removed	Improvement; recurrence; death in two months after second operation.
13	Bruce. <i>Edinburgh. Lancet</i> , 1899, p. 159.	34 years. M.	Central tumor, including pons and vermiform process.	Not found.	Sudden death three days later.
14	Bullard and Bradford. <i>Boston Med. and Surg. Journal</i> , 1891, I, 231.		Tubercle of cerebellum.	Not found.	Death during operation; hemorrhage from wound of superior longitudinal sinus.
15	Carracciolo. <i>R. Polichinico</i> Vol. IX, Fasc. 12.		Tumor of R. cerebellar lobe with compression and displacement of bulb.		
16	Chipault and Raymond. <i>Cliniques</i> , 1898, VIII Lesson	25 years. F.	Tumor (perhaps tubercle) probably situated inside and below left lobe.	Found, but not removed	Improvement; cerebral hernia; reappearance of symptoms after two months.
17	Chipault and Raymond. <i>Cliniques</i> , 1898, VIII Lesson	28 years. F.	Tumor of anteroinferior portion of both lobes, including peduncles	Not found.	No improvement; death several weeks later.
18	Churton. <i>Brit. Med. Jour.</i> , 1899, I, 1098.	30 years. M.	Doubtful tumor (ataxia, headache, etc.)	Not found.	Rapid recovery.
19	Collins and Brewer. <i>Med. Rec.</i> , 1897, May 15.	28 years. M.	Tubercle of right lobe (autopsy)	Removed	Sudden death during second operation, after recurrence.
20	Cuneo. <i>Congr. de chir. It.</i> , 1899.	32 years. M.	Sarcoma of left lobe.	Removed	Death on twentieth day, meningoencephalitis.
21	D'Almeida et Sajanti. <i>Riform. med.</i> , 1896.	19 years. M.	Cystic gliosarcoma of entire cerebellum	Puncture of cyst; tumor not removed	Death on eighth day.
22	Deansley. <i>Lancet</i> , 1901.	14 years. M.	None discovered.	Not found.	Improvement.
23	<i>Ibid.</i>	20 years. M.	Not found.	Not found.	Slow and slight improvement.
24	<i>Ibid.</i>	18 years. M.	Not found.	Not found.	Almost complete relief.
25	Descos. <i>Lyon méd.</i> , XCII.			Not found.	Death.
26	Deaver and Mills. <i>Boston Med. and Surg. Jour.</i> , 1892, II, 221.	11 years. M.	Pulsating tumor of occipital region. Autopsy: diffuse glioma of 4th ventricle and of both lobes	Not found.	Death after several months.
27	Dercum and Heath. <i>Phila. Hosp. Rep.</i> , 1890, I, 270.		Tumor; hydrops of ventricle.	Not found.	Death on fifth day.
28	Diller. <i>Pittsburgh. Med. Review</i> , 1892, 292.	39 years. M.	Autopsy: gumma about as large as a pigeon's egg in right lobe, including the vermiform.	Not found.	Death forty-eight hours after, without return of consciousness.

No.	Authors.	Age, Sex.	Nature and Position of Tumor.	Tumor Found or Not Found.	Results.
29	Durante. <i>Chir. nerv. Chi- pault</i> , Vol. 1, 1902....	11 years. F....	Glioma of median lobe.....	Not found.....	Death twenty minutes later. Enormous dilatation of ven- tricles and aqueduct of Syl- vius.
30	Durante. <i>Ibid.</i>	37 years. F....	Tumor of right lobe.....	Removed	Death one hour afterward from shock.
31	Duret. <i>Congress fr. de chir.</i> , 1903.....	45 years. M....	Sarcoma of left lobe.....	Not found.....	Operative recovery; death six- teen days afterward.
32	Ferrier and Burghard. <i>Brain</i> , 1901.....	12 years. M....	Fibroendothelioma of right lobe.	Removed	Recovery.
33	Fischer. <i>Journal of Nerv. and Ment. Dis.</i> , 1895, 544.	30 years. F....	Glioma of right lobe (autopsy).	Not found.....	Death in the third week (infection).
34	Fison and Luckham. <i>Lancet</i> , 1900, II, 329.....	16 years. M....	Tubercle of left lobe.....	Not found.....	Death four hours after opera- tion.
35	Frazier and McCarthy. <i>N. Y. Med. Jour. and Phil. Med. Jour.</i> , Jan. 22, '04.	10 years. M....	Glioma of right hemisphere....	Removed	Symptoms relieved, improve- ment continuing two months after operation.
36	Frazier and Mills. <i>Ibid.</i>	23 years. F....	Sarcoma of left hemisphere, about size of hazel nut.....	Removed	Recovery.
37	Frazier and Mills. <i>Ibid.</i>	41 years. M....	Tumor not found.....	Not found.....	Recovery from operation, no im- provement; patient declined further operative interven- tion.
38	Frazier and Mills. <i>Ibid.</i>	F.....	Cyst	Cyst evacuated..	Recovery.
39	Frazier and Mills. <i>Ibid.</i>	Adult, M....	Tumor not found.....	Not found.....	Recovery from operation, im- mediate relief from headache, vomiting, vertigo, and dim- ness of vision.
40	Gerster. <i>Am. Jour. of the Med. Sc.</i> , May, 1896....	Tumor	Not found.....
41	Gherardo, Ferreri. <i>Ann. di medicina navale</i> , Feb., 1900. <i>Gaz. heb- dom.</i> , 1900, p. 357....	18 years. F....	Myxosarcoma	Removed	Death in coma some days after operation.
42	Gibson Hildebrandt. <i>Jah- resbericht</i> , 1895.....	25 years. F....	Cystic fibrosarcoma of right lobe	Removed	Recovery.
43	Grainger Stewart. <i>Edinb. Med. J.</i> , 1894.....	Adult, M....	Tumor	Not found.....	Death.
44	Guldenarm. <i>Hermanides. R. S. Weekblad.</i> , 1895, p. 302.....	31 years. M....	Tumor of vermiform, enroach- ing on right lobe.....	Not found.....	Improvement for three months.
45	Guldenarm. <i>Edin. Med. Journal</i> , 1894.....	53 years. F....	Sarcoma of left lobe.....	Removed	Death, the day after operation.
46	Guldenarm and Winkler. <i>Chir. nerv. Chipault</i> , Vol. 1, 1902.....	Endothelioma attached by a pedicle to right tentorium.....	Not found.....	Temporary improvement; death three months later.
47	<i>Ibid.</i>	29 years. M....	Endothelioma of left lobe.....	Removed	Patient greatly relieved; sud- den and unaccountable death.
48	Guldenarm and Ziegen- weidt. <i>Ibid.</i>	41 years. M....	Fibrosarcoma between hemi- sphere and tentorium.....	Not found.....	Death, nine days after operation.
49	Guthrie and Stansfield Col- lier. <i>Brit. M. J.</i> , 1899, II, 1289.....	9 years. M....	Gliomatous cyst of median lobe.	Evacuated	Results perfect after eighteen months, except for persistence of headache.
50	Hedra. <i>Texas M. News</i> , 1902, 380.....	32 years. M....	Tumor, combined with abscess; character of tumor not de- termined	Abscess evacu- ated; tumor not found	Died about eight weeks after first operation.
51	Heldenhain. <i>Arch. f. klin. Chir.</i> , 64, p. 848.....	12 years. M....	Sarcoma, non-encapsulated, me- dian line between superior and inferior vermiform processes.	Not found.....	Died suddenly in collapse night after operation.
52	Herw. <i>Brit. M. J.</i> , 1893.....	Large tumor.....	Not found.....
53	Horsley. <i>Brit. Med. J.</i> , 1887, 818.....	Tumor affecting median lobe....	Two operations; Not found.....	Temporary improvement; death eighteen months later.
54	Hudson. <i>Amer. Jour. of the Med. Sc.</i> , Sept. 1903.	9 years. F....	Cyst of right hemisphere.....	Cyst found and evacuated	Considerable improvement, mod- erate cerebellar hernia; no re- currence.
55	<i>Ibid.</i>	M.....	Tumor, size of pullet's egg, one inch below surface in hemi- sphere	Removed	Patient developed serious diar- rhea, and died from exhaus- tion on eleventh day.
56	Iterson in <i>Hermanides. R. S. Weekblad.</i> , 1895, p. 302.....	13 years. M....	Cyst of left lobe in centre.....	Removed	Recovery, with hernia of cere- bellum.

No.	Authors.	Age, Sex.	Nature and Position of Tumor.	Tumor Found or Not Found.	Results.
57	Jaboulay (Soc. of med. sc. of Lyons, 1899). <i>Progr. inc. méd.</i> , 1899, p. 321.	30 years. M....	Tumor as large as nut in right lobe	Not found.....	Death one hour after second operation.
58	<i>Ibid.</i> , 1901.....	26 years. M....	Chronic tuberculous mastoiditis. Tubercle of right lobe (histological examination)...	Not found.....	Death in coma, nine days later.
59	<i>Ibid.</i> and Lyon <i>méd.</i> , August 11, 1901.....	34 years. M....	Glioma of left lobe.....	Removed	Recovery with persistent deafness in left ear and amblyopia (four and a half months after operation).
60	Jaboulay and Destot. <i>Ibid.</i>	30 years. M....	Fibrocereous tubercle in right lobe	Not found.....	Sudden death after second operation.
61	Jaboulay. <i>Lyon méd.</i> , 1902.	40 years. M....	Glioma, principally in left lobe.	Removed	Disappearance of headache and vertigo; improvement of vision.
62	Jaffe. <i>Deutsche. med. Woch.</i> , 1897, No. 5....	52 years. F....	Fibrosarcoma of right lobe.....	Not found.....	Collapse on table; death twelve hours afterward.
63	Janz. <i>Schmidt's Jahr.</i> , 1897	4 years. M....	Tumor	Not found.....	Death immediately after operation.
64	Janz. <i>Schmidt's Jahr.</i> , 1897	21 years. M....	Tumor	Not found.....	Death immediately after operation.
65	Keen. <i>Am. Jour. of the Med. Sci.</i> , 1894, 38....	14 years. M....	Cystic neuroglioma on floor of third ventricle.....	Not found.....	Death after nine hours.
66	Keen. <i>Am. J. of the Med. Sc.</i> , 1894.....	31 years. M....	Tumor, left hemisphere.....	Removed.....	Immediately after operation considerable aggravation; after 4½ months some improvement.
67	Korteweg and Winkler. <i>Ibid.</i> <i>Trans. Med. and Clin. Soc., Edinburgh</i> Vol. XV.....		Cyst of left lobe.....	Evacuated	Recovery.
68	Krause. <i>Deutsche med. Woch.</i> , 1902.....	11 years. M....	No tumor, internal hydrocephalus	None present...	Very much improved; lived three years.
69	Krause. <i>Deutsche med. Woch.</i> , 1902, No. 51, p. 367	18 years. F....	No tumor, internal hydrocephalus	None present...	Died suddenly, one week after operation.
70	Lamplasi in Lobella (<i>La Psichiatria</i> , 1891, VIII, 261)	2 years.....	Solitary tubercle of left lobe; dilatation of the ventricles...	Not found.....	Death after four days.
71	Lamplasi-Hildebrandt. <i>Jahresbericht</i> , 1895....	45 years. M....	Small tumor		Death thirteen hours after operation.
72	Lloyd, Suckling. <i>Lancet</i> , 1887, II, 863.....	12 years. F....	Glioma affecting whole left lobe and part of vermiciform.....	Partially removed	Collapse after twelve hours; death after forty-eight hours.
73	Macewen. <i>Brit. Med. J.</i> , 1893, II, 1367.....		Tubercles	Two tubercles removed	Improvement; reappearance of symptoms seven months later; death nine months (small tubercle in wall of fourth ventricle).
74	<i>Ibid.</i>		Tumor	Not found.....	Improvement, except for amaurosis.
75	<i>Ibid.</i>		Tumor	Not found.....	Improvement; death in fourth month (pulmonary tuberculosis).
76	Maudsley and Fitzgerald. <i>London Med. Record</i> , 1890	28 years. M....	Tumor of left lobe.....	Removed	Recovered from operation, but remained blind and deaf.
77	Maudsley. <i>Internat. Med. Congress of Australia</i> , 1899	30 years. M....	Glioma	Removed	No return of pains or attacks of vomiting.
78	Mannsell. <i>New Zealand Med. J.</i> , 1899.....	18 years. M....	Hydatid cyst of meninges under tentorium, involving left lobe	Removed	Recovery, with persistence of blindness.
79	Moran and Kerr. <i>Virg. Med. Semi-Monthly</i>		Cyst	Removed	Improved.
80	Munn. <i>Internat. J. of Surg.</i> , 1895, 40.....		Diffuse glioma of right lobe.....	Removed	Improvement immediately following operation; death thirty-six hours later.
81	Murri (of Bologna). <i>Lancet</i> , 1897, I, 291.....	17 years. M....	Fibrosarcoma of left lobe.....	Partially removed	Improvement after one month.
82	Newton. <i>R. E. Australas. Med. Gaz.</i> , 1903, XXII, 219	42 years. M....	Hydatid cyst, containing about 6 drachms, in left hemisphere.	Evacuated	Vomiting and headache relieved at once; nearly all other symptoms subsided.
83	Nota. <i>Chippault. Chir. nerv.</i> , Vol. I, 1902.....	7 years. M....	Tubercle	Not found.....	Death.
84	O'Kynzie. <i>Tuffier. Soc. d'anat.</i> , 1902.....	18 years. M....	Large tubercle of right lobe...	Not found.....	Death on day following second operation.

No.	Authors.	Age, Sex.	Nature and Position of Tumor.	Tumor Found or Not Found.	Results.
85	Parkin. <i>Lancet</i> , Dec. 1896	3 years. M.	Diffuse glioma of vermiform and surrounding parts of median lobe	Removed	Recovery; no recurrence after 2½ years; persistence of optic neuritis.
86	Parry. <i>Glasgow Med. J.</i> , 1893, II, 36.	15 years. M.	Tubercle of posterior part of left lobe.	Removed	Death.
87	Perashing. <i>Med. News</i> , 1898		Glioma	Removed	Death.
88	Portempski. <i>Arch. della Soc. Ital. di chir.</i> , 1892, 21	22 years. M.	Tumor	Not found.	Partial relief.
89	Rotgans and Winkler. <i>Ibid.</i>	21 years. M.	Cyst	Evacuated	Recovery.
90	Saenger. <i>Munch. med. Woch.</i> , 1899, 845.	47 years. F.	Gliosarcoma of base, affecting left auditory and trigeminal nerves	Not found.	Improvement (oozing of cerebrospinal fluid for several weeks); death nine months later.
91	Saenger. <i>Neurolog. Centralbl.</i> , 1899, p. 1117.		Tumor between pons, medulla and cerebellum.	Tumor found; not removed.	Slight improvement.
92	<i>Ibid.</i>			Tumor found; not removed.	Partial recovery.
93	M. Schede. <i>Deutsche med. Woch.</i> , 1900, 477.	Adult. M.	Encapsulated glioma of right lobe	Removed	Recovery.
94	M. Schede. <i>Deutsche med. Woch.</i> , 1900, 477.	17 years. M.	Cystic glioma of right lobe.	Evacuated	Temporary improvement; sudden death several days later.
95	Schönborn (Hirsch). <i>Inaug. Dissert. Würzburg</i> , 1891	24 years. F.	Cystic myxosarcoma of right hemisphere and cuneus.	Tumor found(?)	Temporary improvement; death on eighth day.
96	Springthorpe. <i>Austral. M. J.</i> , 1890, 509.	13 years. M.	Glioma	Not found.	
97	Allen Starr. <i>Brain Surgery</i> , 1893, case XXII.	30 years. M.	Gliosarcoma of left lobe, including pons	Not found.	Death on twelfth day (coma).
98	Starr. <i>Brain</i> , 1893.	10 years. M.	Cystic glioma of right hemisphere	Partially removed	Temporary improvement; death on eleventh day.
99	Starr and McBurney.	7 years. F.	Cystic gliosarcoma of vermiform process, extending to both hemispheres.	Not found.	Death on sixth day.
100	Starr. <i>Brit. M. J.</i> , 10-16, 1897		Glioma, right hemisphere.	Not found.	Improvement; death on eighth day.
101	Starr. <i>Ibid.</i>		Tumor	Not found.	Unimproved.
102	Allen Starr. <i>Brain Surgery</i> , 1893.	(?) F.	Gliosarcoma, subcortical of vermiform, with central cyst.	Not found.	Death on sixth day (convulsions).
103	<i>Ibid.</i>	10 years. M.	Gliosarcoma of right lobe.	Removed	Temporary improvement; death on fourteenth day.
104	Stef. Personall. (<i>Riv. med.</i> , 1900). <i>Revue de neurologie</i> , 1901, 408.	(?) M.	Tumor of lateral lobe.	Removed	Extreme emaciation; meningitis; death.
105	Stieglitz. <i>Journal of Nervous and Mental Disease</i> , 1895, 729.		Gliosarcoma (size of large nut) of right lobe (autopsy).	Not found.	Death (infection, purulent meningitis).
106	Suckling. <i>Am. Jr. Med. Sci.</i> , 1895.	12 years. F.	Glioma, left lobe.	Removed	Death in collapse.
107	Syme. <i>Internat. Colonial Med. J.</i> , 1899.	47 years. M.	Tumor of left lobe.	Not found.	Sudden death from respiratory failure following operation.
108	Tanton. <i>Bull. et mém. de la Soc. anat.</i> , Paris, 1903, III, 584.		Colloid tumor.	Not found.	Death about two months afterward.
109	Terrier in Aubray. <i>Th. de Paris</i> , 1896.	Adult. M.	Tumor of left lobe.	Not found.	Temporary improvement; death two months later.
110	Thomas and Lund. <i>Boston M. and S. J.</i> , 1905.	5 years. M.	Tumor of vermiform.	Not found.	Patient died following morning
111	<i>Ibid.</i>	8 years. M.	Glioma of vermiform with large hydrocephalus	Not found.	Death on fourteenth day.
112	Tricomi. <i>Riforma med.</i> , 1899	9½ years. F.	Glioma of petuncle and quadrigeminal lobe.	Tumor not found	Death on the following day.
113	Von Voss. <i>Deutsche Zeitschrift f. Nervenheide</i> , 1902, XXI, 48.	35 years. F.	Gliosarcoma, left hemisphere.	Not found.	Died in convulsions three days after operation.
114	Weir. <i>Annals of Surg.</i> , 1887, I, 506.	26 years. F.	Tumor	Not found.	Death two months later.
115	Wyman. <i>Med. News</i> , 1890, I, 134.	Adult. M.	Small tumor in left lobe.	Not found.	Death during operation.
116	Ziegenwilde. <i>Psych. en neurol.</i> , 1899.		Suspected in cerebellum on autopsy found between right cerebellum, tentorium, and pons	Not found.	Death.

REPORT OF THREE CASES OF RUPTURED
TUBAL PREGNANCY.

By F. ALAN G. MURRAY, M. D.,

MOUNT SAVAGE, MD.

The following three cases of ruptured tubal pregnancy occurred in my practice within two months of one another. They are the first cases, as far as I can find, that were ever diagnosed in this town, and physicians who have practised twenty years in this region say that they have never had a case in their practice. I used Fowler's position in all three of these cases and also vaginal drainage. I believe that the position and drainage are the only things that saved the patients from developing general peritonitis, as they were all operated on at a few hours' notice, in their own houses, and the rooms in which the operations were done were most decidedly dirty.

In the first case the tube had ruptured thirty-six hours before I saw the patient and she was almost moribund. In the second case the tube had ruptured about six hours before I saw it, and in the third case the tube had ruptured about twelve hours before I saw it.

All patients complained of the same symptoms, a sudden sharp pain in the abdomen, and either fainting or a feeling of faintness and nausea. In the first case the pregnancy was advanced about four weeks, and ruptured in the right fallopian tube about three quarter inch from the uterus. The rupture went through both sides of the tube.

In the second case the pregnancy was about two months advanced and the rupture was in the fimbriated extremity of the right tube. The sac with the foetus in it was about the size of an orange. In the third case the pregnancy was of about five weeks and the tube had partially ruptured several times, as there was some organized clot and strong adhesions existed in and around the left tube. The right ovary in this case was cystic, so I removed it.

The treatment in all the cases was the same. The abdomen was opened in the median line, the blood and clots were cleaned out, the tube and broad ligament tied off in sections, then cut off and the peritonæum was sewed over the stump with a running silk suture. The abdomen was washed out with hot salt solution, an incision made through the posterior wall of the vagina into the cul de sac and a gauze drain about eight inches long pushed through. The abdominal cavity was filled with hot normal salt solution, and the peritonæum brought together with a running silk suture, the muscles with silk worm gut mattress suture and the skin with subcutaneous silkworm gut suture. The patients were put to bed with the head of the bed raised fifteen inches higher than the foot and kept

in that position for ten days. This position caused all blood clots to gravitate to the pelvis and the gauze drain insured free drainage of the broken down material. This position also relieved the patients from nausea and vomiting, as there was no pressure on the stomach by the distended intestines. For the first three days the patients received nothing by mouth, but an eight ounce rectal stimulant injection was given every six hours and strychnine and morphine were administered hypodermically as required. The gauze drain came away in the third week, the drainage ceased, and the vaginal vault healed promptly. Vaginal douches of hot salt solution were given twice a day, beginning the day after operation, and were continued until the drainage ceased entirely. All three of the cases did well and recovered promptly.

CASE I.—November 10, 1903.—Mrs. J. M. Patient had had some uterine bleeding since October 29th; her last regular menstrual period was from October 10th to 14th. On the evening of November 8th she was suddenly taken with a very severe pain in the right iliac fossa and fainted. During that night and the next day and night she had severe pains and fainting spells. I was called in the morning of November 10th and found her in great pain, her pulse 130 and thready, temperature 98°, face pale, black circles under eyes, abdomen distended and tympanic anteriorly, with dullness in both flanks. Severe pain on pressure in right iliac fossa, tongue dry and glazed, vomiting occasionally. On vaginal examination I found a boggy mass in the pelvis very tender on pressure, os patulous, uterus not much enlarged, and some bloody discharge. I called in Dr. Cobey, of Frostburg, who agreed with me as to diagnosis of ruptured right tubal pregnancy. I operated at once with the assistance of Dr. Cobey and two trained nurses. The abdomen was opened in the median line from the umbilicus to the pubes and was found to be filled with blood and clots. I pulled up the right tube and ovary and found blood spurting from a hole which had ruptured through both sides of the tube about three quarter inch from the uterus. The tube and broad ligament were clamped and tied off in sections, then cut off with the ovary, and the stump was reinforced with a running suture and covered over with peritonæum. The abdominal cavity was then thoroughly washed out with hot salt solution, an incision made through the posterior vaginal wall into the cul de sac and a gauze drain inserted. The abdominal cavity was filled with hot salt solution and the peritonæum brought together with a running silk suture, the muscles with silkworm gut mattress suture and the skin with silkworm gut subcutaneous suture. Patient took the chloroform well. Pulse when she came off the table, 130. Gave her strychnine one thirtieth grain, and morphine one quarter grain, hypodermically at once, also one and half pints of salt solution per rectum. The head of the bed was raised fifteen inches. The after treatment consisted of eight ounce nutrient enemata every six hours and strychnine and morphine hypodermically as she needed it. November 11th, patient's

temperature reached 104° and her pulse 160; from this time on her pulse and temperature gradually came down until they reached and stayed normal from November 22d on. During this time there was free drainage from the cul de sac of bits of broken down and disintegrated blood clot. She was douched twice a day. On the fourth day after operation she had her first nourishment by mouth. November 23d, removed skin suture and found the line of incision perfectly healed and firm. November 30th, allowed patient to sit up in a chair. December 10th, made a vaginal examination and found everything healed well; discharged patient cured.

CASE II.—December 23, 1903.—Mrs. G. K. Patient had been sick about one week, complaining of pain in the right side of her abdomen. I saw her several times, but found no marked symptoms of any kind. December 23d, I was called hurriedly to see her and found her with very severe pain in the right iliac fossa, extreme tenderness on pressure, muscles rigid, abdomen distended, pulse 110 and bad, expression anxious, respiration hurried, temperature 97.5°. Immediate operation advised. I called in two trained nurses and a non-medical friend to assist in the operation. One of the nurses administered the chloroform and the friend and other nurse assisted me. I made an incision five inches long and found the abdominal cavity full of blood and clots; on pulling up the ovary and tube a ruptured sac with about a two months foetus showed itself. The sac with the foetus was in the fibrinated extremity of the right tube, and was about the size of an orange. I clamped the tube and broad ligament, tied them off in sections, cut them off with the ovary, and then reinforced the stump with a running silk suture and buried it under the peritonæum. The abdominal cavity was thoroughly flushed out with hot normal salt solution, an incision made through the posterior vaginal wall into the cul de sac, and a gauze drain inserted. The abdominal cavity was then filled with hot salt solution and sewed up, the peritonæum with running silk suture, the muscles with silkworm gut mattress suture, and the skin with silkworm gut subcutaneous suture. Patient reacted well from the operation. Gave her strychnine one thirtieth grain and morphine one quarter grain, hypodermically, also one and one half pints of hot salt solution per rectum on putting her to bed. The head of the bed was raised fifteen inches, three hours after the operation. December 24th: Patient rested fairly well during night. Abdomen distended. Morning temperature 101°, pulse 108, respiration 24. December 25th: Vomited dark green matter several times during night and passed a good deal of flatus with assistance of rectal tube. Morning temperature 100°, pulse 160, respiration 26. From this time on patient gradually improved and on January 6, 1904, the suture was removed from the skin, and the scar found to be firm. January 16th, removed rest of vaginal drain. January 22d, discharged patient, well.

CASE III.—January 9, 1904.—Mrs. C. H. Patient had been sick about two weeks, complaining of cramps in her left side, low down in the pelvis. She

had had some uterine bleeding off and on for the last ten days. Prior to this time she had not menstruated for six weeks. Vaginal examination during this time showed some tenderness over both ovaries and tubes, and the uterus slightly enlarged. During night of January 8th patient was taken with very severe cramps in the left side. January 9th, Dr. Quarles and I saw her together and found her very pale, suffering severe pain, abdomen distended, very tender on pressure and considerable uterine bleeding. Temperature 98°, pulse 120 and small. Diagnosis, ruptured left tubal pregnancy. Prepared patient for operation at once. On opening the abdomen it was found full of blood and clots. Pulled up the left tube and ovary. They were adherent to the intestines everywhere and the tube was ruptured and bleeding freely. The tube and broad ligament were tied off in sections and the adhesions broken up, then they were cut off with the ovary, and the stump was reinforced with a running suture and buried under the peritonæum. The right ovary was cystic, so, together with the tube and broad ligament, was removed. The abdominal cavity was flushed out with hot salt solution, an incision made through the posterior wall of the vagina into the cul de sac, and a gauze drain inserted. The abdominal cavity was then filled with hot salt solution, the peritonæum brought together with a running silk suture, the muscles with silkworm gut mattress suture, and the skin with a silkworm gut subcutaneous suture. Patient took the chloroform fairly well. Pulse 150 at close of operation. Gave her strychnine one thirtieth grain and morphine one quarter grain hypodermically, also one and half pints of hot salt solution per rectum. Elevated head of the bed fifteen inches. Patient was desperately ill for the first five days after the operation, then she gradually became convalescent and was discharged, well, February 26th. She drained very freely from the cul de sac up to February 24th and if the discharge checked at all she would have fever and pain. Suture removed from line of incision January 22d, and the scar found to be firm.

On Auxiliaries of Climatotherapy.—I. Benney Yeo, in the *Practitioner*, for December, 1904, refers to a previous statement by him that "care without climate is better than climate without care," and that "it is possible to make bad use of a good climate and good use of a bad one." In other words, something more than unaided change of climate is necessary in the treatment of tuberculosis and hence arose the method of treating this disease in sanatoria.

The care in such institutions means strict attention to the smallest details of a patient's life. This rigid care which is exercised over tuberculous patients ought also to be exerted over patients who are sent to sanatoria for the treatment of chronic gastric catarrh, early hepatic cirrhosis, diabetes, albuminuria, chronic rheumatism, chronic paludism, and many other forms of chronic disease. With suitable regulation of diet, baths, exercise, and amusements many troublesome cases that are now neglected might be cured.

REPORT OF A CASE OF FIBROMATA OF
THE VULVA.*

By THOMAS S. BURR, A. B., M. D.,

SOUTH BEND, IND.,

FORMERLY ASSISTANT IN SURGERY AND DEMONSTRATOR OF
GYNAECOLOGY AND OBSTETRICS IN THE UNIVERSITY
OF MICHIGAN.

I wish to report the case here cited, not because it offers any features of spectacular interest, or presents a solution of any surgical problem, but because the condition is one which but seldom comes to the attention of the profession. Benign neoplasms of the vulva are rarely encountered. In consulting the gynaecological records of the University Hospital, I have not found a recorded case of fibroma of the vulva among some 5,000 gynaecological conditions observed. Forty-two essays bearing upon this subject have been collected from the literature, and of these I have been able to study eighteen. The paucity of reported cases seems to bear me out in the statement that such growths are rare, though the fact that small tumors of the vulva are easily dealt with makes it possible that the condition is met with by the general practitioner more frequently than reported cases would lead us to believe.

Just why the vulva should be so exempt from the development of fibroma and other tumors, is not easily apparent. Certainly the tissues of the vulva are rich in mesoblastic elements. There is an abundance of connective tissue and smooth muscle fibres, and the structures are singularly liable to traumatism which in other localities are often sufficient to inaugurate cellular new growth. The life history of the labial tissues is in no essential different from that of similar tissues in other parts of the body. The same phenomena of development maturity and atrophy pertain here as elsewhere, and the same ætiological factors should be operative here as in other localities, where fibromata are more commonly found.

The tumors described by the writers to whose articles I have had access, range from small sessile circumscribed growths, in some cases partaking of the nature of elephantiasis, to very large pedunculated masses, reaching in one case (Holzman), from the right labium majus to the knee, and weighing 6,850 grammes. Most of the tumors reported, however, were small, ranging from the size of a walnut to that of a goose egg. In two cases the age of the patient ranged from 35 to 52

years; in three cases the age was from 22 to 28, and one case was reported in a girl of 18 years. With one exception the patients were married and had borne children. In six cases the growth originated from the right labium majus; in eight, from the left labium majus; in one, from the left labium minus; and in one, from the right labium minus. In two cases the location of the growth was not noted. In nine cases the tumors were pedunculated. The duration of the growth varied from ten months to nine years, all but one, however, having endured for more than four years. Pathologically there were 5 fibromata dura, 3 fibromata mollia, 6 fibromyomata, 2 fibromyxomata, and 2 cystofibromata. Of these two were so closely upon the border line of sarcoma, that the diagnosis was doubtful. In two of the cases reported, ulcerative changes had occurred in the skin.

The history of these cases had no apparent bearing upon the condition of which the patient complained. Surgical relief was sought because the growths were inconvenient by reason of their location. In several cases the history states that at the time of menstruation the growths became congested, and in some instances quite swollen and painful.

The case which I wish to report was admitted to the University Hospital August 25, 1902.

The patient was an American, 42 years old. She had been married twenty-one years, and had had four children and three induced abortions. Aside from the local trouble the history was otherwise negative. The patient first noticed a growth upon the vulva eighteen years ago. This growth, the size of a bean, was situated in the upper third of the left labium majus. The lump rapidly grew to the size of a walnut. It remained thus for six years when it was removed. Six years later the patient noticed another growth similar to the first one, but situated lower down in the lower portion of the left labium majus. Five years later, one year ago, two smaller growths appeared, one immediately above the one just described, and the other still higher up, in the upper portion of the labium majus, just to the left of the clitoris, in about the same position as the original growth which had been removed. These tumors gave no symptoms other than those of annoyance by reason of their position. The last two growths developed more rapidly than either of the others.

Examination showed the growths located as described. The upper, as large as a hickory nut, apparently developing from scar tissue, presented a median furrow and was fixed. The middle nodule, a little larger, was slightly movable, non-sensitive, and rather soft. It was smooth, well outlined, and seemed to be connected with

* Read before the Michigan State Medical Society, at Detroit, June 8, 1903.

the larger mass below. The third growth, the lowest, was the size of a large walnut. It was firm, somewhat bosselated, and non-sensitive. All three of these tumors seemed to have their origin in the tissues of the labium majus, but the lower two encroached somewhat upon the labium minus and the perinæum. The pelvic organs were practically normal.

The patient was operated upon August 26, 1902. The middle and lowest fibroids were enucleated through a median incision, shelling out very readily. The upper tumor was removed by an elliptical incision, which included the surrounding scar tissue. The wound was closed by sutures of silkworm gut, deeply placed so as to obliterate all spaces. The closed incision made a continuous linear wound, placed between the left labia majus and minus. The wound healed per primam, and the patient was discharged September 10th. Eighteen months later there had been no recurrence of the growths. The pathologist, Dr. Ralph Morse, reported the tumors to be fibromata mollia.

Although the number of cases reported is too small to serve as a basis for the establishment of hard and fast conclusions, still an analysis of them may be of interest. It will be seen that from the standpoint of ætiology, the age and social condition of the patient are of importance. In the majority of the cases cited, the tumors appeared from the thirty-fifth to the fifty-second year in women who were married and had borne children. Veit, in discussing the ætiology of fibromata of the vulva, lays considerable stress upon the irritation of the tissues due to coition, and the facts in the cases reported bear out his observations. Veit also states that in many cases the initial condition is one of elephantiasis, the connective tissue elements and muscle cells subsequently taking on more active growth, and the tumor resulting from this cell proliferation. The fact that wide lymphatic spaces, sometimes sufficiently extensive to be classed as cysts, are occasionally found in vulval fibromata forms the basis of this assertion. Fibromata may develop from the fascial structures, from the round ligaments, or from other connective tissue elements in this region. The left labium majus was most often the seat of development in the cases which I have reported, and the labia minora were less frequently involved. The tumors were pedunculated in 50 per cent. of the cases. In but one case, that of Kirchoff, were multiple growths reported.

The diagnosis of fibromata of the vulva should not be difficult. Small growths may be differentiated from elephantiasis by the fact that the fibroid is sharply outlined and more or less movable under the skin. Elephantiasis vulvæ is a condition of diffuse thickening due to inflamma-

tion and hypertrophy of the lymphatic channels. Cysts of Bartholin's glands are thin walled, globular shaped structures, and give the peculiar movable fluctuating feel characteristic of retention cysts. It is especially important to recognize carcinoma of the vulva, which is also a rare condition. Carcinoma is characterized by rapidity of growth, early infiltration of the surrounding tissue, tendency to early ulceration, and involvement of the neighboring lymphatics. Pain, a prominent symptom in carcinoma, is absent in these fibroid growths. Lipomata of the vulva are rather more common than fibromata. They are usually larger, softer, and are perhaps oftener pedunculated. From a clinical standpoint their differentiation is unimportant. Inguinal hernia descending into the labial structures may produce a mass resembling a new growth. It is to be differentiated by the history of the patient, by the possible presence of distensile expansion on coughing, by the percussion note if the hernial sac contains gut, and by its possible reducibility. The diagnosis between hernia and new growth may be difficult as in a case reported by Tuttle, in which incision for fibroid revealed a structure resembling a hernial sac. Careful investigation showed it to be a cystic fibroma, having its origin in the tissues of the round ligament. The importance of recognizing a hernia in this location is apparent. The diagnosis between fibroma molle and sarcoma, can usually be made only by the microscope, and in at least two of the cases studied even the microscope failed to make a satisfactory distinction. The border line between the two conditions is exceedingly shadowy.

The only treatment of fibromata of the vulva is surgical. Benign growths of the vulva are no menace to the life of the individual; but as malignant tumors and especially sarcoma in their early stages often simulate innocent growths, prompt removal of any neoplasm is indicated. Mesoblastic growths are easily enucleated. If a capsule is present it should be removed. Pedunculated growths are best dealt with by making an elliptical incision around the base of the mass, and ligating the pedicle with catgut. Hemorrhage is usually slight, but should be thoroughly controlled, especially in those tumors originating in the inguinal canal. Sutures should be deeply passed to close dead spaces. In every case the material removed should be submitted to the pathologist, and if the tissue is found to be malignant, radical measures should be instituted. The employment of the microscope in diagnosing these conditions cannot be too strongly urged.

In case of doubt, treat the patient for the more serious condition.

The case which I have reported is interesting from the fact that three distinct tumors were present, one of which occurred at the site of removal of a previous growth. The fact of recurrence, with the pathological evidence in the case, might lead to the suspicion that these growths were sarcomatous, but up to the present time there has been no recurrence.

A CASE OF MANIA A POTU AND EPILEPSY.

By HENRY F. COLLINS, M. D.,
FRANKLIN, ME.

The following case of a young unmarried woman, with a history of chronic alcoholism in the father, may prove of interest from the fact that mania a potu and epilepsy were coexistent and because of the manner in which the one morbid condition affected the other.

L. M., female, aged 29 years, height five feet, eight and one half inches, unmarried, and of robust and intelligent appearance. The patient gave the following family history: Remembered nothing of her grandparents on either side of the family; her father used alcoholic beverages "moderately," and died from "disease of the liver" at the age of forty-seven years. Her mother was still living and had had good health until two years previously, since which she had suffered from a heart lesion giving rise to attacks of faintness. She had three sisters, all of whom had "fits," such as she had, and a brother who had good health.

The subject did not remember of any illness during her childhood, but at about the age of fifteen years she began to have "fits." They usually occurred at the menstrual period, but not at every period. They became less frequent under treatment, and for about two years she was free from seizures. They returned, however, and though the menstrual function was normal, the attacks nearly always occurred a day or two before menstruation began.

About five or six years before, she began the use of alcoholic beverages, principally whiskey and mixed drinks. She had continued their use steadily, but seldom became drunk. Had at times drunk cologne and once about seven months ago had delirium tremens.

For two days before the present attack the patient presented symptoms of great mental depression and threatened suicide, apparently because of a great disappointment. She began drinking heavily, and in about twelve hours the first epileptic convulsion occurred. This was severe and when I arrived she was in coma, which lasted about fifty minutes, when she became restless, began muttering, and then talked incessantly of beautiful flowers, hideous faces, frogs, mice, snails, and finally of a deep pit into

which she thought she was falling. She begged piteously to be saved from the fall, then with the cry that she was going, another violent convulsion came on. The seizure lasted for about five minutes, followed by a period of coma of forty minutes, which in turn was followed by hallucinations. These epileptic seizures alternating with periods of mania recurred until she had had five attacks of *grand mal*, growing less violent and at longer intervals when she lapsed into coma with muttering and jactitation lasting for ten hours. She then became conscious, asked for water, recognized those around her, and then for a space of about fourteen hours was extremely restless and sleepless. During this time her temperature ranged from 101° to 102° F. Following this she lapsed into quiet slumber for several hours, and on awaking complained of heaviness and pain in the head, soreness and pain in the muscles, and great weakness. The tongue was badly bitten during the first seizure, and I may add that a silver tablespoon placed between her teeth during that first convulsion was pierced by one of her canine teeth. Afterward a piece of wood wrapped with gauze was used.

One interesting feature of the case was that the mania terminated each time in a convulsive seizure with a sensation of falling. The pulse was rapid and soft, except during the convulsions, when it was slower and full. The urine was voided involuntarily during the epileptic attacks.

Five weeks after this illness the patient moved to a distant place and was lost sight of, but during that time she had no more seizures and seemed to be in normal health.

The treatment consisted in the administration of sulphate of morphine hypodermically in $\frac{1}{4}$ grain doses, chloral in starch water per rectum, and the use of the ice cap and small amounts of liquid nourishment at frequent intervals.

How to Cook Rice.—Physicians and others who have eaten rice cooked by a Hindoo, a Chinaman, or a Southern dinky, must have remarked the difference between the results obtained by these artists and those of the benighted cooks of the North. We learn from an authoritative source that the secret lies in the following recipe: The rice should be carefully washed and placed in a kettle of boiling water, which should be set on the back of the range over a low fire, where the rice should simmer slowly until done. Stirring is not only useless but harmful. If there is any water left, it should be drained off carefully and the rice should then stand in a hot place for some time. Nothing should be added during the cooking; no salt, sugar, milk, or butter. If the cooking has been done properly, each grain of rice will stand out by itself, plump, dry, and beautiful. Served very hot at the table the rice should then be reverently treated with cayenne pepper and butter, after which will be revealed to the consumer one of the secrets of the success of the Japanese army.

REPORT OF A CASE IN WHICH A BULLET CAUSED NINE PERFORATIONS OF BOWELS: OPERATION AND RECOVERY.

By J. B. BOUCHER, M. D.,

HARTFORD, CONN.,

SURGEON TO ST. FRANCIS'S HOSPITAL.

July 4, 1904, I was called to see John R., aged 15 years, with the following history:

While celebrating the Fourth about 10 a. m. with a companion, the latter aimed at patient a revolver, supposed to contain a blank cartridge. The result was a perforating wound about two inches to the left of and below the umbilicus. The wound was large enough to admit a lead pencil, the skin being burnt and black in a circle about the wound.

I saw the patient about 4 p. m. He had then a temperature of 103, pulse 120, extreme pain in abdomen, and the appearance of a very sick boy.

I ordered his removal to St. Francis's Hospital for operation. At 6 p. m. same day, the patient, having been prepared, we dissected out the wound in the abdominal wall expecting to find the bullet. Removing the entire tract down to the peritonæum, we found a perforation of the latter, which was apparently not larger than a pin head. We then decided to enlarge the incision and investigate further.

When the abdomen was opened we found a perforation with black and burnt margins extending through the omentum. This would admit the little finger. The wound was carefully dissected, when we found the bullet had passed through the mesentery of the small bowel, about one eighth inch below its attachment to the gut.

We noticed the contents of the bowels free in abdominal cavity. Examination of the bowels revealed nine different perforations in the small intestines, three pairs where the bullet passed through both sides of the bowel and three single perforations, extending over a distance of several feet. These were repaired by turning in the bowel and using a double Lembert with silk. Several gallons of hot saline solution were used, washing out the cavity thoroughly. Gauze drainage was inserted and the wound closed.

The following day the temperature dropped to 100° and the second day to normal. The patient made an uninterrupted recovery and left the hospital in four weeks. He is now attending school and perfectly well.

One of the deceptive points about this case was the absence of perforation through the peritonæum. The small opening of which I wrote could not be detected until the peritonæum was raised with forceps and looked at from the side. Even then there was no indication of the burnt margin noticed in the other perforations. The bullet was not found.

25 CHARTER OAK AVENUE.

Therapeutical Notes.

Terpin Hydrate in Cough.—*Revue française de médecine et de chirurgie*, for December 12, 1904, gives the following formulæ for the administration of terpin:

- B Terpin hydrate.....5 centigrammes ($\frac{3}{4}$ grain); Venice turpentine.....enough to make one pill.
- M. Two to six pills daily.
- B Terpin hydrate / of each.....5 centigrammes
Sodium benzoate / ($\frac{3}{4}$ grain);
Extract of aconite.....1 milligramme ($\frac{1}{100}$ grain).
- M. Two to six pills daily.

Treatment of Warts.—Kaposi is cited in *Nouveaux remèdes*, for January 24, 1905, as advising:

- B Mercury bichloride.....1 gramme (15 grains); Flexible collodion......30 grammes (1 ounce).
- M. Paint the warts once daily.

Mercurial Treatment of Leprosy.—De Luca, in the *Revue de thérapie*, for October 1, 1904, states that he has investigated in seven cases of tuberculous, nervous, and mixed leprosy the action of mercury employed as intramuscular injections of calomel and intravenous injections of sublimate. The ulcers healed rapidly under this treatment, but leprous nodules which were not ulcerated were not affected. A certain amount of improvement occurred in two cases of nerve leprosy. Injections of calomel especially had a rapid action on the cicatrization of ulcerations, but the effect was not permanent. The author attributes this to interruption of treatment, and proposes to continue these for longer periods.

Influence of Cold on the Heart.—In *Berliner klinische Wochenschrift*, for April 28, 1904, is an article by Dr. W. Krebs, on The Influence of Local Applications of Cold on the Force of the Heart. As the result of a series of observations, the author arrives at the conclusion that: (1) In many cases in which weakness of the heart is present, whether this be of nervous or organic origin, the local application of cold acts favorably. This favorable influence is manifested by an improvement in quality of the pulse, by elevation of arterial pressure, and regularity of pulse frequency; (2) the best results are obtained when the apparatus for the local applications of cold is made use of in conjunction with strict repose on the part of the patient; (3) in other cases, beyond a certain subjective influence, no objective action results; (4) but the results obtained by this mode of treatment cannot be compared with those due to the action of digitalis.

Removal of the Crystalline Lens in Myopia.—H. Dickson Bruns is cited in *Médecine orientale*, for September 25, 1904, as stating that this operation is contraindicated in young myopes where there is no pathological change of the fundus, and even in young and middle aged myopes with considerable lesions. It is valuable only in selected cases of very advanced myopia in subjects from ten to thirty-five years of age, and should be performed on one eye first. The result should be carefully noted before operating on the other eye.

NEW YORK, SATURDAY, FEBRUARY 18, 1905.

CIVIL SERVICE EXAMINATION AND MUNICIPAL
MEDICAL SERVICE.

The city of New York has had some recent experience which, it seems to us, ought to have some effect on those of its citizens who have thus far been able to see nothing but unalloyed benefit in the civil service examination system. It is but a few months since the board of trustees of the Bellevue and Allied Hospitals were balked by the system in an attempt to place an important executive office in the hands of a certain gentleman whom we all know to be peculiarly qualified for the efficient performance of its duties. Not long thereafter we were informed that the city Health Department was "up against" the same obstacle in its very laudable purpose of giving some pecuniary compensation to a special advisory board consisting of a number of eminent physicians, because some of them, not being residents of New York, were giving a portion of their valuable time in visits to the city incident to the high functions that they had generously consented to assume. And now comes the information that Health Commissioner Darlington is encountering the same impediment in his policy of going beyond the civil service list in quest of a desirable person to appoint to a new office calling for exceptional qualities on the part of its incumbent.

Commissioner Darlington recently appeared

before the civil service commissioner to ask for the creation of an office that he wished to fill "without competition and practically at his own discretion." He stated specifically that he wished to appoint "a gentleman with whom he was intimately acquainted, in whose character and ability he had the greatest confidence, and who had for some years performed like duties in the Finance Department." He required a thoroughly trustworthy man, as the appointees furnished to the commissioner from the eligible list of the Civil Service Commission needed careful watching by some one in whom he had implicit personal confidence. Dr. Darlington stated that while the men recommended from the commission might be well fitted for the tasks to which they were assigned, those tasks were of such a character as to require more than an ordinary degree of confidence in the integrity, capacity, and tact of the appointees, and that the personal element was so large a factor in the fitness of the appointee that the restriction to the list furnished by the Civil Service Commission was a marked disadvantage to the department. Dr. Darlington was quoted as stating that he was unable to check many of the evils prevailing in his department which had grown up out of this limitation of his powers of selection.

In discussing this matter with a representative of the *New York Medical Journal*, Dr. Darlington said that he appreciated fully the able, honest, and efficient cooperation which he received from the professional members of his staff, and that he regretted that the newspaper reports might tend to create an impression that he was in antagonism to these men, to whom the department was so greatly indebted, but notwithstanding the efficiency of these professional assistants, Dr. Darlington was pronounced in his antagonism to the present method of selection which was imposed upon him by the Civil Service Commission. The *New York Times*, in commenting on this incident, says: "As to the exemption from competition of the inspector whom Dr. Darlington desires, it would seem that the doctor's friend ought to be able with his ability, training, and experience to get to the head of any reasonable eligible list." Whatever saving grace there may be in the word

"reasonable," we doubt if the admirable Crichton himself could get to the head of such a list; moreover, we hope never to see the day when a man whose services are sought for will so far lower himself as to submit to a competitive examination at the hands of a civil service commission.

STERILITY AND THE X RAY.

It would have been amazing if there had not come up something more serious than burns to check what may be called the triumphal progress of the Röntgen rays in medicine. That something seems at last to have been encountered, at least if there is final truth in what has recently been put forward concerning the influence of the rays upon the sexual glands. They are said to destroy the power of the testicles to elaborate potent spermatozooids and that of the ovaries to produce ovules susceptible of fertilization. In other words, they blot out the reproductive power in an individual, male or female, whose sexual glands come under their influence. Whether this blasting effect is lasting or only temporary does not appear to have been settled as yet, even if we may set it down as absolutely established that it occurs at all in the great majority of cases.

At all events the impression that exposure of the testicles or ovaries to the action of the Röntgen rays is destructive of their procreative function has to a great extent taken possession of medical men, and it is sure to spread to the laity. What is to be the result? As regards the testicles, probably it will be of little consequence. In the case of the ovaries, however, fear of injuring their power of ovulation, both on the part of the physician and on that of the patient, seems likely to interfere materially with the availability of the rays for diagnostic purposes so far as the pelvic contents in women are concerned. Moreover, this dread may work moral disaster, for we fear it cannot be doubted that there is many a woman who would eagerly destroy within herself the potentiality of maternity if she thought she could accomplish her object by so simple an expedient as exposure to a subtle agency that would not give her pain or endanger her life or leave upon her a physical stigma that would lay her open to the suspicion of having resorted to such

an unworthy device. On these accounts it is to be hoped that our present impression of the danger to fertility of exposing the sexual glands to the action of the Röntgen rays may prove to have been hastily formed.

VARICOCELE IN SOLDIERS.

A discussion has arisen among some of the medical officers of the British army as to the extent to which varicocoele may properly be considered as a bar to the enlistment of an otherwise acceptable recruit. It seems that the regulations governing recruiting allow of the acceptance of a young man who is the subject of varicocoele, provided the varicose condition is of moderate (but not precisely indicated) degree. Varicocoele is so common in young men, so rarely gives rise to serious trouble, and not infrequently becomes so unproductive of symptoms as middle age is approached that a priori we should be inclined to regard its existence in a healthy young man as constituting at most no more than a minimum objection to the man as a recruit.

One of the contributors to the discussion, as it has thus far been published in the *Journal of the Royal Army Medical Corps* for February, is Captain Robert J. Blackham, who may be presumed to have considered the disease with exceptional carefulness, as he states that his own admission into the army was made conditional on his undergoing an operation for its cure; and it seems to us that the conclusions he has arrived at with regard to its being a bar to military service are mainly such as are supported by general observation. Varicocoele, says Captain Blackham, works a disability from which the patient may recover spontaneously, but it generally becomes aggravated until middle age is reached. It is often the cause of intense neuralgia, and sometimes produces profound depression of spirits and other nervous symptoms. Therefore it is right to look upon it as a bar to enlistment, though it is almost always curable by means of a simple operation. Illogical as it may seem, his implied advice to accept the subjects of varicocoele for enlistment and then submit them to a curative operation in a military hospital—illogical, that is to say, on the ground that a technically unallowable enlistment must be allowed before recourse to the

military hospital becomes possible—seems worthy of being followed. "Likely recruits," he says, "whose only bar to enlistment is a moderate degree of varicocele might be passed into the service on the understanding that they submit to an operation as soon as possible after enlistment." If such an understanding is susceptible of enforcement, we see no objection to it.

THE TEACHING OF THE HISTORY OF MEDICINE.

It will, I believe, be admitted that the average physician of to-day, although he knows much more about disease and is far better equipped to treat human maladies, is possessed of much less culture and refinement, and occupies a position much lower in the regard and esteem of his fellow citizens, than the physician of fifty or a hundred years ago. This condition of affairs is largely due to the tendencies of modern education. There is a very general movement toward abbreviating the so called undergraduate studies of students who seek a medical education, in order that more and more time may be given to strictly professional work. It seems to be taken for granted by those in charge of general educational affairs that it is important to make it easier for a young man to acquire a medical education, and the natural result of this will be that more and more of the young men of the future will take up the study of medicine. Were there a dearth of physicians in our communities there might be some reason for encouraging young men to study medicine, but there being, as is well known, many more physicians in nearly all of our communities than are needed, it seems to me that a medical education should be made more difficult instead of easier to obtain. I believe, too, that we should have better physicians and that our profession would stand higher in the public esteem if more attention were given to the study of those subjects which make for the general culture of the individual, not only in undergraduate life, but during the years of professional training as well. It is true that the horizon of medicine is constantly widening and that the hours of medical study are lengthening and becoming more and more crowded with the new details of anatomy, pathology, diagnosis, and treatment which he must master. These facts, however, do not seem

to me to be good reasons for shortening either the term of preliminary education or the term of medical education, but rather, in view of all the facts, I should consider them good reasons for lengthening both terms. True, if we make it more expensive and more difficult to obtain a medical education, we shall have fewer aspirants for the medical degree. This, it seems to me, would be a more desirable condition of affairs than exists at the present time. We need to educate fewer physicians and we need to educate them more broadly and better. It is not sufficient for our medical schools to turn out men who are masters of the human machine, as a machine, but we need cultured, educated physicians with a breadth of mind which will make them students of human nature as long as they live and which will enable them to stand as leaders among men. Men so educated should have a knowledge, not only of the medicine of to-day with some foresight into the medicine of the future, but also a knowledge of the medicine of the past and of the lives and struggles of those who have made the medicine of to-day what it is. Therefore I would have the history of medicine taught as a part of the curriculum of all of our medical schools.

There is no department of education which does so much to broaden the individual and give character to culture as the study of history, and no branch of human knowledge can be mastered in the broadest sense of the word without studying the history of the lives and struggles of those who have previously labored as pioneers in the same field. As a profession we do not cherish and honor as we should the heroes of medicine, and if we ourselves are ignorant of the traditions and history of our science and pay little heed to them, is it any wonder that others not of our profession should have little knowledge of them? The names of those who have achieved great deeds in other walks of life are sung by the poet, written by the story teller, or recorded with reverence by the historian, and their names are writ high upon the tablets of the Halls of Fame. Why should the names of the masters of medicine be forgotten and neglected? It is because we neglect them ourselves. Students of medicine are elaborately instructed concerning all the special branches of medicine and surgery, but they gain no knowledge as to who were the pioneers along the

special lines they are studying, as to who first recognized and described certain diseases, who first devised and performed certain surgical operations, or who first discovered and accurately described the structure and functions of certain organs. Names, to be sure, are often used, but more as adjectives than as proper nouns, since many diseases, surgical operations, and anatomical structures have been given the names of those who first described them, but nothing is taught as to who these persons were, when or where they lived, or what their influence was upon the science of medicine. Those who have not had their taste stimulated by at least a brief sketch of the wonderfully fascinating story of the history of medicine are deprived of a very great pleasure, the pleasure of knowing where to look and how to look and of wanting to look for more knowledge about the early history of some special department of medicine in which they are especially interested.

I am not advocating an exhaustive and elaborate course of study on the history of medicine, such as is given in our universities on general history, but it is rather a brief account of the different periods of medical history, with sketches of the lives of the leading men in each period, and a more or less detailed description of the great discoveries which have made epochs in the history of medicine, which should form a part of the broad education of every physician. Open the volume here and there and give the student a taste of its interesting contents, and he will eagerly turn to the pages himself in later life with ever increasing pleasure and profit. There has been of late years an awakening of interest in the subject of medical history, but as yet it has not reached our medical schools, except here and there, and so far as I know there are but two regular courses of lectures given upon this subject in the United States. I feel sure, however, that the time is not far distant when the importance of broader medical education, an education which will tend to produce medical men of deeper learning, of more culture, and of greater refinement, will be recognized, and when in the broader curriculum of the future there will be included a systematic course of teaching on the history of medicine.

BURNSIDE FOSTER.

ANOTHER UNIVERSAL LANGUAGE.

We have received from A. Maloine, of Paris, a volume containing a grammar, exercises, and a dictionary of Spokil,¹ another of the fashionable "universal" languages. We have little faith in any attempt to impose upon the world, even the credulous scientific part of it, a hastily manufactured language, and Spokil seems to us, if anything, a trifle more barbarous than its congeners, resembling nothing in the heavens above, the earth beneath, or the waters under the earth. If people wish to study other languages than their own, why not undertake one that possesses a literature to reward the pains taken? Mediæval Latin and modern Greek seem to have qualifications as a universal language that none of these hastily compacted makeshifts can ever acquire.

THE POSSIBLE PERIL OF STATING A SCIENTIFIC FACT.

We learn from the *Progrès médical* for January 28th that a widow lately brought a suit for damages against the publisher of a graduation thesis entitled *De l'imprégnation de la mère*. It seems that the thesis presented the subject of indirect atavism, and that the widow's fiancé, horrified at the idea, derived from reading it, that his future progeny might inherit the traits of the woman's deceased husband, broke the engagement. We fancy she will not recover damages.

THE HATFIELD PRIZE.

We would particularly call our readers' attention to the notice, published in our news columns, of the Nathan Lewis Hatfield prize for original research in medicine, to be awarded by the College of Physicians of Philadelphia. The subject announced, The Clinical and Pathological Diagnosis of Sarcoma, is one that may well interest clinical and laboratory investigators, and the amount to be awarded is large enough to repay a man for extensive research.

THE MEDICAL GEWALT.

This amusing annual, supposed to have some occult connection with the alumni of Mt. Sinai Hospital, has recently been received at this office. We are lampooned in it, in company with several others of the editorial guild, but its sallies are so good-natured that we have derived the usual pleasure from their perusal.

¹ *Spokil, langue internationale*. Par le Dr. Ad. Nicolas, médecin consultant à la Bourboule. Paris: A. Maloine, éditeur.

News Items.

Society Meetings for the Coming Week:

MONDAY, February 20th.—New York Academy of Medicine (Section in Ophthalmology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, February 21st.—New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, February 22nd.—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society; New York Dermatological Society (private); Auburn, N. Y., City Medical Association; Berkshire, Mass., District Medical Society (Pittsfield).

THURSDAY, February 23rd.—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; New York Celtic Medical Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Mass., Society for Medical Improvement (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, February 24th.—New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, February 25th.—New York Medical and Surgical Society (private); Harvard Medical Society, New York (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending February 11, 1905:

	February 11.		February 4.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	201	3	185	8
Diphtheria and croup.....	275	42	311	49
Scarlet fever.....	246	14	233	15
Smallpox	3	1	1	1
Chickenpox	101	..	135	..
Tuberculosis	368	181	343	180
Typhoid fever.....	28	4	32	10
Cerebrospinal meningitis.....	..	29	..	33
	1,222	274	1,240	296

A Mistake Regarding the Site of a Fire.—We are requested to state that the William Street fire of February 11th did not affect the Empire State Engraving Company, which has much of this *Journal's* half tone work on hand, but a firm of somewhat similar name.

Cerebrospinal Meningitis has gained such prevalence during the last month, especially among children of this city, that a return of the epidemic which swept over the city a year ago and which was checked only after hundreds of deaths had been recorded, is feared. Three boys died on February 10th in Bellevue Hospital from the disease, a record which the worst days of a year ago did not equal.

The New York Skin and Cancer Hospital.—The governors of the New York Skin and Cancer Hospital announce that Dr. L. Duncan Bulkley will give a special course of four lectures on *The Relation of Diseases of the Skin to Internal Dis-*

orders in the out patient hall of the hospital on Wednesdays at 4.15 p. m., commencing March 1, 1905. The course will be free to the medical profession. William C. Witter, chairman of executive committee.

The Medical Library and Historical Journal, of 1313 Bedford Avenue, Brooklyn, N. Y., owing to the almost total destruction by fire of the establishment of its printers on February 13th, begs to ask the kind indulgence of its subscribers and advertisers for delayed publication of the January, 1905, number. Fortunately, duplicate copies of all important communications were made before sending them to the printer, so the heavy loss incurred by the *Journal* will not be shared by its contributors or readers. The editor desires to announce that immediate steps have been taken for the making of new plates and duplicating the entire number which was in press, and that this issue will be published at the earliest possible date.

The Oppenheimer Institute.—We have been requested to publish the following announcement:

The undersigned, who have hitherto allowed their names to be used as approving of the Oppenheimer Institute, are constrained hereby to withdraw their endorsement. While there is much of which they approve in the method of the Oppenheimer treatment, the character of the advertisements used, based as are some of them on unproved assertions and especially the exploiting of a philanthropic as a commercial enterprise; the unusual means that have been employed in the issue of stock; all make them unwilling that their names should longer appear as endorsing an enterprise for which they are unable to assume any responsibility.

HENRY C. POTTER,
C. H. PARKHURST,
ROBERT COLLYER,
L. D. KENNEDY.

New York, February 15, 1905.

The New York State Medical Association, New York County.—A stated meeting of this association will be held on Monday, February 20th, at 8 p. m. Programme: Presentation of clinical cases or reports, pathological specimens, new instruments, etc.; A Memorial to Dr. M. L. Maduro, by Emil Mayer, M. D.; "Symposium" on Alcohol; Alcohol in Health, by Professor Russell H. Chittenden, of Yale University, New Haven, Conn.; Alcohol in Disease, by George L. Peabody, M. D.; Wood Alcohol, by Mr. J. P. Atchinson, chemist to the New York Board of Health; Legislative Aspects of Alcohol, by the Honorable Maynard Y. Clement, New York State Deputy Commissioner of Excise; Substitutes for Alcohol, by Charles B. Fitzpatrick, M. D.; discussion by Professor Graham Lusk, Dr. Crothers, the Honorable De Lancey Nicoll, Dr. Mason, and others.

Brooklyn Branch of the Board of Health.—Health Commissioner Darlington and Dr. T. L. Fogarty, the assistant sanitary superintendent for the borough of Brooklyn, are now actively engaged in looking for a site on which to build headquarters for the board of health in that borough. When such a site is secured the board of estimate will be asked for \$100,000 for the erection of a modern building. The officials have been driven to activity by the unsanitary and rundown condition of the quarters in Clinton Street that are

now used by the department. They were condemned by the last grand jury. Commissioner Darlington has several sites in mind, but it is said that he favors one that will be more centrally situated than the downtown section of the borough.

Academy of Medicine.—The section in ophthalmology will meet on Monday, February 20th, at 8.15 p. m. Order: Presentation of Patients; (a) Wood Solinter Ten Weeks in the Anterior Chamber, with Encapsulation and Accompanying Iritis, and Consequent Removal, by A. Wiener, M. D.; (b) Case of Retraction Movement of the Eyeball, by A. Schapring, M. D.; (c) Epithelioma of the Conjunctiva and Cornea, by the chairman. Presentation of New Instruments: Model of a New Bifocal Glass, by George S. Dixon, M. D. Reports of Cases: A Clinical and Pathological Report of a Case of Annular Scleritis, by Edward L. Oatman, M. D. Paper, The Advantages of Röntgen Ray Diagnosis in Ocular Injuries from Foreign Bodies, with Demonstration of Method of Localization, by William M. Sweet, M. D., of Philadelphia; discussion by Dr. C. T. Kipp, Dr. T. R. Pooley, Dr. E. Gruening, Dr. P. A. Callan, Dr. F. M. Wilson, and others; paper, Unilateral and Other Unusual Forms of Nyctagmus, by Alexander Duane, M. D. Wilbur B. Marple, M. D., chairman; Herbert W. Wootton, M. D., secretary, 35 West Forty-fifth Street.

The section in medicine will meet on Tuesday, February 21st, at 8.15 p. m. Order: Presentation of Cases and Specimens; Clinical Reports: An Unusual Case of Chorea, by William B. Noyes, M. D.; papers with discussions, (a) Contribution to the Alcohol Question, by S. T. Beebe, Ph. D.; (b) The Treatment of Renal Inadequacy Complicated by an Apparent Nephritis, by W. J. Pulley, M. D. Charles H. Lewis, M. D., chairman; E. E. Smith, M. D., secretary, 26 East Twenty-ninth Street.

The section in laryngology and rhinology will meet on Wednesday, February 22nd, at 8.15 p. m. Order: Presentation of Cases; (a) Adenocarcinoma of Nose; Radical Operation, by J. J. McCoy, M. D.; (b) Peculiar Laryngeal Cough (barking) in a Young Girl, by George B. McAuliffe, M. D.; (c) Melanosarcoma with Local Manifestations in the Upper Air Passages, by Wendell C. Phillips, M. D. Paper, (a) Report on the Use of Stovaine, by C. G. Coakley, M. D. Discussion of the Forms, Pathology, Diagnosis, and Treatment of Non-Malignant Growths of the Larynx, to be opened by Dr. C. H. Knight, Dr. D. Bryson Delavan, Dr. C. C. Rice, and Dr. W. Kelly Simpson. (Members having cases of this class are requested to present them at this meeting.) Specimens and New Instruments: (a) A Chair for Rhinologists and Laryngologists; (b) A Nasal Septometer, by Henry Wallace, M. D. Lewis A. Coffin, M. D., chairman; Lee Maidment Hurd, M. D., secretary, 15 East Forty-eighth Street.

The section in obstetrics and gynecology will meet on Thursday, February 23rd, at 8.15 p. m. Order: Presentation of Specimens. Paper, Is Craniotomy on the Living Child Ever Justifiable, by Simon Marx, M. D.; discussion will be opened

by Dr. E. H. Grandin, and continued by Dr. E. A. Ayers, Dr. M. McLean, Dr. Austin Flint, Jr., Dr. J. O. Polak, Dr. J. D. Voorhees, and others. Charles F. Adams, M. D., chairman; Arnold Sturmdorf, M. D., secretary, 51 West Seventy-fourth Street.

PHILADELPHIA.

American Oncologic Hospital.—At a meeting of the trustees, held last month, Dr. G. Oram Ring was elected consulting ophthalmic surgeon to this hospital.

Personal.—Dr. Alfred Gordon has been appointed chief of the clinic of nervous and mental disease at Jefferson Medical College and examiner of the insane at the Philadelphia General Hospital.

The Ladies' Auxiliary of the Mount Sinai Hospital opened a bazaar at 507 South Eighth Street on the evening of February 10th. The proceeds will be devoted to the needs of the hospital, which is to be dedicated in the near future.

License of a Lying-in Establishment Revoked.—On February 2nd the board of health revoked the license of Mrs. Matilda Hughes for the maintenance of a lying-in establishment at 503 North Sixth Street, because of irregularities which were reported to the board by the coroner.

Appointed to the State Board of Medical Examiners.—The Governor of Pennsylvania sent to the Senate on February 1st the names of W. D. Hanaker, of Meadville, and M. P. Dickson, of Glen Riddle, as his appointees on the Pennsylvania State Board of Medical Examiners for three years.

Annual Dinner at Southern Dispensary.—The directors of the Southern Dispensary, 318 Bainbridge Street, held their annual dinner at the hospital, at which they entertained the twenty-five members of the staff. The directors are: John Thompson, Charles Thompson, John Middleton, Dr. William H. Hickman, and Paul J. Fields.

German Hospital Trustees Organize.—The trustees of the German Hospital organized for the year on January 31st with the election of the following officers: President, Hermann Hessenbrück; vice-president, M. Richards Muckle; secretary, Reverend F. Wischan; treasurer, Edmund R. Teubner; solicitor, Joseph G. Rosengarten.

Concert for the Benefit of the University Hospital.—On Thursday afternoon, February 9th, the Philadelphia Orchestra gave a concert of popular music in Horticultural Hall for the benefit of the men's medical ward of the hospital of the University of Pennsylvania. Refreshments were served during the concert, which lasted from 3.30 to 6.

Infallible Cure for Tuberculosis.—At the meeting of the Philadelphia County Medical Society on January 25th, Dr. Henry N. Fisher complained that two licensed practitioners of medicine were obtaining money from poor Italians in the south-eastern part of the city by professing to have an infallible cure for consumption. The matter was referred to the censors.

Officers of the Neurological Society.—The following officers were elected at the meeting of the Philadelphia Neurological Society on December 24, 1904: President, Dr. Joseph Sailer; vice-presidents, Dr. Charles S. Potts and Dr. William Pickett; secretary, Theodore H. Weisenburg; treasurer, Dr. J. H. W. Rhein; council, Dr. Charles K. Mills, Dr. William G. Spiller, Dr. D. J. McCarthy.

State Hospital for Tuberculosis.—In the State legislature, Representative Hutt, of Philadelphia, introduced a bill on February 1st, for the selection of a site and the erection of a State hospital for the treatment of incipient tuberculosis. The institution is to be located within the limits of the State forestry reservation in Franklin county, of which from 500 to 1,000 acres are set aside, and an appropriation of \$200,000 is provided by the bill for the accomplishment of its provisions.

Polyclinic Hospital.—The following is a statement of the work done at the Polyclinic Hospital and College for graduates in medicine during January, 1905: Patients admitted to house, 124; patients discharged, 104; new patients treated in dispensary, 1,597; total visits to dispensary, 7,513; accident ward, 593. The week beginning February 6th was devoted to special clinics, lectures, and demonstrations of diseases of the ear, nose, and throat.

Publishers Fined.—Judge McPherson, in the United States Circuit Court, fined the Historical Publishing Company \$10.00 and costs for sending by express a medical book containing an immoral paragraph. The book was one of the class of family medical works, known as "medicology," of which the company claims to have sold 400,000 copies. The paragraph, which caused the prosecution and which is said to have been written by a reputable medical man, dealt with the prevention of pregnancy. The objectionable paragraph has been expunged from the book.

Scientific Society Meetings for the Week Ending February 25, 1905.—Monday, February 20th, Medical Jurisprudence Society; Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, February 21st, Section in Ophthalmology, College of Physicians; Dermatological Society; Academy of Natural Sciences. Wednesday, February 22nd, Philadelphia County Medical Society. Thursday, February 23rd, Pathological Society; Entomological Section, Academy of Natural Sciences. Friday, February 24th, South Branch, Philadelphia County Medical Society; Northern Medical Association.

The Nathan Lewis Hatfield Prize for Original Research in Medicine, Awarded by the College of Physicians of Philadelphia.—Five hundred dollars will be awarded to the author of the best essay submitted in competition on or before March 1, 1906, on the subject of The Clinical and Pathological Diagnosis of Sarcoma. Essays must be typewritten, designated by a motto or device, and accompanied by a sealed envelope bearing the same motto or device and containing the name and address of the author. They must embody original observations and researches. The com-

mittee reserve the right to make no award if none of the essays submitted is considered worthy of the prize. For further information address Francis R. Packard, M. D., chairman, College of Physicians, 219 South Thirteenth Street, Philadelphia, Pa.

Deaths.—Dr. Michael O'Hara died at his home, 227 South Twentieth Street, on January 31st, aged 72 years. Dr. O'Hara graduated from the medical department of the University of Pennsylvania in 1852, so that in 1902 he was able to celebrate the fiftieth anniversary of his entrance into the profession. Dr. O'Hara's preliminary education was obtained in the public schools of Philadelphia. During the Civil War he was assistant surgeon in the United States Navy and later surgeon of the One Hundred and Fiftieth Regiment of Pennsylvania Volunteers. Dr. O'Hara was visiting physician to St. Mary's Hospital and to the House of the Good Shepherd for many years; he was medical director of St. Agnes's Hospital from 1894 to 1898. Dr. O'Hara was a member of the Medical Society of the State of Pennsylvania, of the Philadelphia County Medical Society, and of numerous other scientific bodies.

Changes of Address.—Dr. B. T. R. Clark, to Bala, Pa.; Dr. J. Coles Brick, to 1210 Spruce Street; Dr. S. W. Latta, to 223 South Fourth Street; Dr. E. L. Graf, to 5214 Spruce Street; Dr. J. Howe Adams, to Paoli, Pa.; Dr. E. E. Keiser, to 6933 Tulip Street; Dr. Joseph M. Asher, to 1355 North Broad Street; Dr. Clifford B. Farr, to 326 South Seventeenth Street; Dr. J. Eugene Fahy, to 804 South Forty-ninth Street; Dr. T. Ridgway Barker, to 1703 Spruce Street; Dr. Rebecca Fleisher, to northwest corner Broad and Locust Streets; Dr. Charles S. Barnes, to 41 South Nineteenth Street; Dr. F. I. Hurlock, to 2831 Diamond Street; Dr. H. Brooker Mills, to 114 South Eighteenth Street; Dr. George D. Morton, to 139 South Fourth Street, room 202; Dr. Samuel McClary, 3d, to 308 South Fifty-second Street; Dr. Mazyck P. Ravenel, to 908 Pine Street; Dr. Harry W. Weyant, to 911 North Forty-first Street; Dr. F. H. Miliken, to 3708 Walnut Street; Dr. William A. Steel, to 2528 North Fifth Street; Dr. Charles C. Royce, to Ardmore, Pa.

For a Better Milk Supply.—The milk exchange adopted the following rules in January for the guidance of its members engaged in producing and distributing milk: First. Cows shall be healthy and free from any disease. Second. Milk from any cow suspected of being ill shall be discarded from the herd milk. Third. The dairyman and his household must be free from any contagious disease. Fourth. Milk pails used in milking should have a covered top, with a small opening, protected by wire sieve and cloth strainer. Fifth. All cans and dairy utensils shall be scrupulously clean before using. Sixth. No milk to be kept or sold from living rooms or any room connected with the stable. Seventh. Absolute cleanliness of bottles and bottling apparatus. Eighth. Clean room for filling bottles. Ninth. Clean boxes for storage of bottles or cans, with

drains connected to avoid sewer gas. Tenth. Delivery wagons to be thoroughly clean, both inside and outside. Dr. A. C. Abbott has suggested the following measures, which he hopes the milk exchange will adopt: First. That all milk cans be thoroughly washed before being returned to the farms or dairies. Second. That dairymen and milk dealers generally effectively screen all rooms in which milk is handled, so as to exclude flies.

The Health of the City.—During the week ending February 4th, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Malarial fever.....	1	0
Typhoid fever.....	76	7
Scarlet fever.....	56	3
Chickenpox.....	52	0
Diphtheria.....	56	9
Cerebrospinal meningitis.....	4	0
Measles.....	10	0
Whooping cough.....	3	3
Tuberculosis of the lungs.....	56	56
Pneumonia.....	84	82
Erysipelas.....	15	3
Anthrax.....	1	0

The total deaths for the week was 538, in an estimated population of 1,438,318, corresponding to an annual death rate of 19.45 per 1,000 population. The total infant mortality was 94; 75 under one year and 19 between one and two years. There were 45 still births; 28 males and 17 females. The following deaths from other transmissible diseases were reported: Tuberculosis other than tuberculosis of the lungs, 10; puerperal fever, 2; dysentery, 3; diarrhoea and enteritis under two years, 17. The temperatures were low, ranging from a minimum of 7° on the second to a maximum of 27° on the first. There were two snow flurries.

Medical Society Programmes.—The following was the programme of the Society of Normal and Pathological Physiology, University of Pennsylvania, at the meeting held February 6th: The Experimental Production of Monsters, by Professor E. G. Conklin; On the Action of Copper and Copper Salts Upon Bacteria in Water, by Dr. N. Gildersleeve; Studies on Cell Granula, by Professor Leo Loeb.

The meeting of the Philadelphia County Medical Society, held February 8th, was devoted to a "symposium" on Gastric Ulcer. The following papers were read: Dr. Joseph McFarland, *Ætiology and Pathology*; Dr. A. P. Francine, *Incidence in Philadelphia*; Dr. Campbell P. Howard, of Johns Hopkins Hospital, by invitation, *Symptomatology and Diagnosis*; Dr. Frederick P. Henry, *Medical Treatment*; Dr. W. L. Rodman, *Surgical Treatment*.

The following programme was offered at the meeting of the Pathological Society of Philadelphia, held February 9th: Dr. W. M. L. Coplin, *Specimens from a Case of Hæmorrhagic Pancreatitis*; Dr. A. O. J. Kelly, *Specimens from a Case of Hæmorrhagic Pancreatitis*; Dr. J. H. Musser (a), *Cancer of the Pancreas*; (b), *Duodenal Ulcer and Cirrhosis of the Liver*; (c), *Ulcerative Endocarditis*; (d), *Cancer of the Stomach and Peritonitis*; Dr. J. Funke and Dr. S. S. Cohen, *Syphilis of the Liver—Sclerogummatous*

Type; Dr. H. R. M. Landis, *Tuberculosis of the Liver*; Dr. D. J. McCarthy, *two card specimens*.

The following was the programme of the Northern Medical Association at its meeting, February 10th: *Ætiology and Pathology of Dilatation of the Stomach*, by Dr. E. B. Sharp, of Camden, N. J., by invitation; *Diagnosis and Prognosis of Dilatation of the Stomach*, by Dr. John H. Musser, by invitation; *Medical Treatment of Dilatation of the Stomach*, by Dr. Albert Bernheim; *Surgical Treatment of Dilatation of the Stomach*, by Dr. John B. Deaver. The discussion was opened by Dr. J. P. Strittmatter and Dr. Judson Daland, by invitation.

The following was the programme of the section in general medicine, College of Physicians, at its meeting, held February 13th: Dr. A. O. J. Kelly exhibited a patient recovered from Pyopneumothorax after Spontaneous Evacuation through a Bronchus and Subsequent Resection of a Rib; Dr. A. A. Eshner, *Universal Congenital Atichia*; Dr. Sailer, Dr. Geisler, and Dr. Welty, *Polycythæmia and Cyanosis*, with a Report of Two Cases; Dr. J. Norman Henry, *Paratyphoid Fever*, with a Report of Six Cases; Dr. T. L. Coley, *Diet in Typhoid Fever*.

The following was the programme of the Philadelphia Pediatric Society at its meeting, held February 14th: Dr. Robert S. McCombs exhibited an Infant with Nodding Spasm; Dr. William J. Taylor, *Case of Pseudomuscular Hypertrophy*; Dr. J. P. Crozer Griffith, *Case of Chronic Cerebrospinal Fever, slowly recovering*; Dr. George W. Norris, *Child with Multiple Exostoses*; Dr. J. P. Crozer Griffith, *Fatal Case of Chorea*.

GENERAL.

La Grippe in Springfield, O.—There are said to be over 2,500 cases of la grippe in Springfield, O.

Scarlet Fever in Syracuse, N. Y.—Eighty-three cases of scarlet fever are reported from Syracuse in private houses only.

Accident to a Hudson, N. Y., Physician.—Dr. H. N. Brown, of Hudson, was severely injured by a fall on the railroad track near Stockport Centre, on February 8th.

Ramsey County, Minn., Medical Society.—The Ramsey County Medical Association held their annual meeting and election of officers on January 30th. The following physicians were elected officers: President, Dr. A. W. Dunning; vice-president, Dr. Burnside Foster; secretary, Dr. E. S. Geer; treasurer, Dr. Frederick Leavitt; and necrologist, Dr. A. F. Whitman.

City Hospital, Louisville, Ky.—Dr. Clyde Brady, of Greenup, Ky., has been appointed by the faculty of the Kentucky School of Medicine as an interne at the City Hospital, to fill the unexpired term of Dr. William Fullbright, who resigned recently to accept a position as physician at the Texas Insane Asylum.

The Orange County, N. Y., Medical Society has elected officers as follows: President, Dr. E. D. Woodhull, of Monroe; first vice-president, Dr. F. W. Dennis, of Unionville; second vice-presi-

dent, Dr. John T. Howell, of Newburgh; secretary and Treasurer, Dr. L. G. Distler, of West-town.

The Columbia County, N. Y., Medical Society has elected the following officers: President, Dr. O. Howard Bradley; vice-president, Dr. Eloise Walker; secretary and treasurer, Dr. Hortense V. Bruce; fellow to State association meeting, Dr. T. Floyd Woodworth, of Kinderhook; alternate fellow, Dr. H. W. Johnson.

German Hospital, Newark.—During the past year nearly \$40,000 was spent on the German Hospital in Newark, N. J., in improvements. To assist in raising funds for the institution, singers from the Metropolitan Opera House, New York, will present the operas *Faust* and *Il Trovatore*, in Newark on March 6th and 7th.

Dinner to Dr. Rodman.—Dr. William L. Rodman, the Philadelphia surgeon and professor, as guest of honor, was entertained by Dr. Joseph Dudley Irwin with a theatre party in Louisville on January 26th, and a dinner at the Pendennis Club afterward. With him, as Dr. Irwin's guests, were some of the physicians of Louisville.

Franklin County, N. Y., Medical Society.—At the fiftieth annual meeting of this society, held on January 10th, the following officers were elected: President, Dr. C. C. Tremblay, of Saranac Lake; vice-president, Dr. W. A. Wardner, of St. Regis Falls; secretary and treasurer, Dr. George M. Abbott, of Saranac Lake; censor, Dr. George E. McClellan.

Teller County, Colo., Medical Society.—The following officers have been elected to serve during the coming six months: President, Dr. V. R. Pennock, of Cripple Creek; vice-presidents, Dr. T. M. Latimer, of Victor; Dr. B. F. Jones, of Goldfield, and Dr. J. A. McIntyre, of Florissant; treasurer, Dr. J. A. Dunwoody, of Cripple Creek; and secretary, Dr. H. G. Thomas, of Victor.

Cook County, Ill., Hospital.—A new medical ward, with 100 beds, will be opened at the Cook County Hospital as a result of action by the public service committee on January 20th. This committee concurred in the desire of the hospital committee that the old ward for contagious diseases at the county hospital be changed into a medical ward. The contagious disease patients are now taken to the new hospital for contagious diseases. The alterations will cost about \$4,000.

Nurses Graduated from the Denver County Hospital.—The following young women graduated from this institution on January 12th: Ida May Mercer, Elizabeth S. Belcher, Vida Matthews, Cynthia P. Dozier, Edna McHenry, Minnie J. McCrossen, Catherine E. Wilkin, Marie M. Farner, R. Virginia Bainard, Jessie B. Leckliter, Edith V. Orman, Clara A. Stevens, Margaret A. Wheatley, Carrie M. Richardson, Catherine B. Crockford, Margaret Fitzgerald, Mary C. Trafford, Christine A. Hammon, and Flora V. Plumley.

Cleveland City Hospital.—Dr. D. T. Hanson was elected president of the staff of physicians

of the Cleveland City Hospital at the annual meeting of the staff on January 17th. Dr. J. N. Lenker was elected vice-president, and Dr. C. C. Stewart was elected secretary. An elaborate medical library is being planned for the hospital. There is no large library of medical literature at the hospital at this time and the members of the staff have been quietly taking the matter up during the past year.

Samuel Merritt Hospital, Oakland, Cal.—Permission has been granted to the trustees of the Samuel Merritt Hospital fund to begin work on the big enterprise provided for by the will of the late Catherine Garcelon, who bequeathed property worth \$750,000 for the erection of a free hospital for incurables. Owing to complications and the fact that much of the property left by the deceased is real estate not readily disposed of, the project for which the means were left has been delayed since 1891.

Nurses Graduate at St. Luke's Hospital, St. Paul.—The annual commencement of the St. Luke's Hospital training school was held on January 17th, when eight nurses were graduated. The exercises were held in the guild hall of Christ Church, and the following received diplomas: Margaret Crowl, of Currie; Florence Grady, of Chippewa Falls; Etta Francis, of St. Paul; Beatrice Locke, of West Duluth; Della Sweeney, of Anoka; Cora Quinn, of Spring Valley; Frances Fawcett, of St. Paul; Margaret McGregor, of Hawley.

Chautauqua County, N. Y., Medical Association.—The election of officers of this association, held on January 24th, resulted as follows: President, Dr. V. D. Bozovsky, of Dunkirk; first vice-president, Dr. B. S. Swetland, of Brocton; second vice-president, Dr. Morris N. Bemus, of Jamestown; secretary and treasurer, Dr. H. A. Eastman, of Jamestown (reelected); trustees, Dr. H. F. Hunt, of Dewittville (reelected); fellows to the meeting of New York State Medical Association at New York in October, Dr. William M. Bemus, of Jamestown; Dr. George F. Smith, of Sinclairville; and Dr. J. A. Weidman, of Dunkirk.

Dr. Charles H. Herty, a graduate of the University of Georgia, has been elected professor of chemistry in the University of North Carolina. For the past year Dr. Herty has been in the service of the government in the forestry department. This position of professor of chemistry in the University of North Carolina was offered him a year since, but he was not in position to accept the place. The University of North Carolina was anxious to secure his services, however, and held the position open for a full year in order to get a favorable reply from Dr. Herty. Dr. Herty will take charge of his new work July 1st.

Civil Service Examinations for the State and County Service.—The State Civil Service Commission announces general examinations to be held March 11, 1905, including the following positions: Matron, State hospitals for the insane; orderly (male nurse), Erie County Hospital; stew-

ard (woman), institutions for women; veal inspector; woman physician. State hospitals and institutions. Applications for these examinations must be made on or before March 7th. Full particulars of the examination and blank applications may be obtained by addressing the Chief Examiner of the Commission at Albany.

Dr. Leonard J. Gordon, of Jersey City, died on January 18th, after a long illness, aged 62 years. He was a lieutenant during the Civil War and for ten years after its close was a Wall Street broker. He then studied medicine at Bellevue and practised for a time in Jersey City, later becoming chemist at Lorillard's tobacco plant, a position he retained until five years ago, when he resigned to become director of the Jersey City Public Library. Dr. Gordon was one of the best known and most public spirited citizens of Jersey City, and his benefactions were multitudinous. The city officials are preparing a great memorial service in memory of Dr. Gordon, and his bust will be placed in the Public Library.

Illinois State Board of Health.—The Illinois State Board of Health held its annual meeting on January 31st, in Springfield. The old officers were elected as follows: President, Dr. George W. Webster, of Chicago; secretary, Dr. J. A. Egan, of Springfield; treasurer, Dr. P. S. Wessel, of Moline. Plans for the board's crusade against tuberculosis were mapped out, and a bill recently introduced in the legislature providing for the establishment of a State hospital for consumptives was approved. In the report of William G. Laub, chief lodging house inspector in Chicago, it is stated that basement lodging houses and those formerly having "double deck" and "triple deck" beds, with small air space and poor ventilation, are no longer to be found in that city.

LeFlore County, Miss., Medical Society.—The LeFlore County Medical Society held its regular monthly meeting in Masonic Hall, Greenwood, on February 6th, Dr. Dickens presiding. President-elect Dr. S. A. Eggleston was installed as president; Dr. J. H. Lucas, vice-president; Dr. D. S. Humphreys, secretary and treasurer; and Dr. S. L. Brister, censor, were also installed. Dr. Eggleston's presidential address on The Prophylaxis of Consumption was read and discussed. Dr. S. L. Brister submitted his paper on Dysentery. Dr. J. M. Anderson was unavoidably detained from attending, so the society was denied the pleasure of hearing him. An attractive programme for the March meeting was arranged as follows: Hematuria, by Dr. J. W. Armistead, of Sidon; discussion, led by Dr. W. B. Dickens, of Greenwood; Pneumonia, by Dr. W. T. Matthews, of Greenwood; discussion, led by Dr. C. N. D. Campbell, of Greenwood. After some further routine business the society adjourned for luncheon.

Statement of Mortality in Chicago for the Week Ending February 11, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Feb. 11, 1905	Feb. 4, 1905	Feb. 13, 1904
Total deaths, all causes.....	554	530	961
Annual death rate per 1,000.....	14.50	13.88	17.88
By sexes—			
Males.....	310	297	379
Females.....	235	233	282
By ages—			
Under 1 year.....	123	114	118
Between 1 and 5 years.....	82	70	83
Over 60 years.....	105	104	144
Principal causes of death.....			
Acute intestinal diseases.....	20	23	14
Apoplexy.....	19	16	14
Bright's disease.....	32	36	40
Bronchitis.....	40	28	30
Consumption.....	68	67	71
Cancer.....	29	20	25
Convulsions.....	14	11	20
Diphtheria.....	11	13	11
Heart disease.....	37	33	36
Influenza.....	12	6	7
Measles.....	5	5	0
Nervous diseases.....	21	23	31
Pneumonia.....	118	115	175
Scarlet fever.....	1	1	5
Smallpox.....	2	6	0
Suicide.....	8	5	6
Typhoid fever.....	4	3	4
Violence other than suicide.....	20	31	33
Whooping cough.....	10	7	0
All other causes.....	84	85	139

Continued deficiency of sunshine is the probable cause of the increased mortality rate of the week—probable, because the increase is exclusively among the young, those under five years of age. It is this age period which is the most susceptible to climatic influences, and the increase of most of the contagious diseases of childhood may be fairly attributed to the lack of bactericidal action of sunshine during the past few weeks.

Advice to Patients With Venereal Disease.

The following instructions are printed by the Ohio State Board of Health and sent in circular form to practitioners for distribution among their patients suffering from venereal disease:

Circular of Information Adopted by the Conference of State and Provincial Boards of Health of North America.

Issued by the State Board of Health of Ohio.

We hand you this leaflet believing that you would not willingly communicate your disease to some innocent person.

Many fail to comprehend the exceedingly disastrous results that often follow these diseases. Many cases of blindness, complete disability, and not infrequently death result from them. Gonorrhea is one of the most frequent causes of diseases peculiar to women. So serious a menace have these diseases become to the public health that the medical profession and sanitarians in all countries have become alarmed, and are advocating measures for their prevention.

Syphilis (or pox) is especially a disease from which innocent persons may suffer, as it usually produces sores in the mouth or on the lips, hence may be conveyed by kissing, drinking from the same cup, or using anything which has been put to the lips or into the mouth of one affected by the disease.

These diseases are often communicated when the patient thinks he has recovered. Hence marriages contracted at this time of the disease result in much unhappiness, and often in the death of the wife. To protect yourself and others, we earnestly advise the following in the interest of prevention of your disease:

Follow strictly the advice of your doctor, and use no other treatment.

Remember that it takes a long time to recover entirely.

Carefully wash your hands with soap and hot water whenever you handle the private parts.

Do not have intercourse and avoid all sexual excitement until your physician says you are completely cured. Be especially careful not to rub your eyes with your fingers.

Do not allow any person to use any cup, glass, spoon, fork, or anything that you have put in your mouth.

Do not kiss any one or wipe the face of a child with a handkerchief you have used. Always use a separate towel. Burn all cloths or cotton soiled by discharges.

Pith of Current Literature

PRESSE MEDICALE.

January 11, 1905.

1. Traumatic Rupture of the Spleen and Resection of the Cartilaginous Border of the Thorax,

By MAURICE AUVRAY.

2. The Abdominal Cutaneous Reflex in Typhoid Fever and in Appendicitis in Children,

By J. A. SICARD.

1. **Traumatic Rupture of the Spleen.**—AUVRAY considers the location of the abdominal incision to be of great importance in the operation for removal of a ruptured spleen. In order to reach the injured viscus through an incision made in the location of his choice he finds it necessary to resect the cartilaginous ends of the ribs, beginning with the ninth.

2. **Abdominal Cutaneous Reflex.**—SICARD observed this reflex in 26 cases of typhoid in children, and in 22 found it either absent or greatly diminished on each side. In 2 cases the change was very transient, and in 2 cases no change whatever was observed. In appendicitis he found the reflex absent on the right side, normal on the left.

January 14, 1905.

1. Phagetic Ulcers of Hot Countries and Their Treatment,

By M. FONTOYNONT and E. JOURDRAN.

2. Non-Specific Serums in the Treatment of Tumors,

By TH. TUFFIER.

1. **Ulcers of Hot Countries.**—Fontoynont and Jourdan describe the ulcers of the foot and leg met with in Madagascar, called by them "l'ulcère malgache." The treatment employed was to paint the ulcerated surfaces each morning with a watery solution of eserine, 5 to 100, and expose them all day to the rays of the sun. During the night a protective dressing, either moist or dry, was applied.

2. **Serums and Tumors.**—Tuffier believes that the same effects are to be obtained from the injection of non-specific serums into tumors as from the injection of Loeffler's serum.

January 18, 1905.

Convulsions and Sleep,

By R. CRUCHET.

Convulsions and Sleep.—Cruchet reports two cases of convulsions of functional origin which occurred or persisted during sleep.

SEMAINE MEDICALE.

January 4, 1905.

How to Apply Dressings in Pott's Disease, By Dr. CALOT.

How to Apply Dressings in Pott's Disease.—Calot describes at length and with ample illustrations the method of making extension and of applying a plaster jacket in disease of the vertebrae.

January 11, 1905.

1. Nephritis from Sublimite Poisoning,

By M. A. CHAUFFARD.

2. The Mortality of General Anæsthesia with Scopolamine-Morphine.

1. **Nephritis from Sublimite Poisoning.**—Chauffard describes a severe attack of nephritis

caused by the ingestion of a solution of corrosive sublimate, in which there was complete suppression of urine for five days.

2. **General Anæsthesia With Scopolamine-Morphine.**—In an unsigned article it is stated that this method of general anæsthesia, which was introduced by Schneiderlein in 1900, has a mortality of about 1 per cent. In 1897 the mortality from chloroform anæsthesia was given as 1 in 2,075, that from ether 1 in 5,112.

January 18, 1905.

Operative Intervention in Chronic Arthritis Deformans,
By F. LEJARS.

Operative Intervention in Arthritis Deformans.—Lejars discusses the various operations which have been undertaken for the relief of this condition, and they vary from simple arthrotomy to resection of the hip joint, and finally concludes that operative intervention has not been of great service in this disease.

LYON MEDICAL.

January 15, 1905.

1. Paraplegia with Muscular Flaccidity, Exaggeration of the Patellar Reflex and Epileptoid Trepidation,

By M. LANNOIS and A. POROT.

2. A Case of Embolism of the Superior Mesenteric Artery,

By F. LECLERC and CH. BEUTTER.

1. **Paraplegia.**—Lannois and Porot describe a case of paraplegia with complete relaxation and atony of the muscles, epileptoid paroxysms of violent tremulous movements of the feet, complete anæsthesia, and retention of urine and fæces. On autopsy the seventh cervical, the first, second, and third dorsal vertebrae were found to be carious. The subjacent spinal cord was removed for histological examination, which revealed the presence of an intense, diffuse, transverse myelitis with ascending and descending degeneration of the cord.

2. **Embolism of the Superior Mesenteric Artery.**—Leclerc and Beutter report a case in which a tentative diagnosis of embolism of a mesenteric artery was confirmed at autopsy.

BERLINER KLINISCHE WOCHENSCHRIFT.

January 2, 1905.

1. Emphysema of the Lungs,

By J. ORTH.

2. The Function of the Labyrinth (*To be concluded*),

By PASSOW.

3. On Urticaria,

By J. BAUM.

4. Objective, Demonstrable Cardiac Changes, Especially in Pericarditis After Attacks of Angina Pectoris,

By W. KERNIG.

5. The Therapeutic Value of Griserin,

By SCHOMBURG.

6. Scurvy Among Nurslings in Berlin,

By H. NEUMANN.

7. Adrenalin in Surgical Practice,

By HILDEBRANDT.

3. **Urticaria.**—Baum has observed that a wheal can be produced upon the skin by slight traumatism induced by ethylene glycol. He has examined microscopically the lesions thus produced. There is no exudation of white or red cells and the veins show no circulatory disturbance. Before the wheal arises, there is a dilatation of the capillaries.

4. Objective Changes in the Heart.—Kernig says that after severe attacks of angina pectoris, a rise of temperature is often seen which can be attributed to changes in the myocardium. In other cases objective changes in the heart may be observed in which there is a dilatation of one of the chambers of the heart. The author reports a case in which the left auricle became dilated. Another group of cases shows the evidence of a pericarditis with or without the formation of a transudate. The practical deduction is to keep patients after an attack of angina pectoris in bed for weeks or months to prevent sudden death. Kernig believes that the essential element of anginal attacks lies in the closure of the coronary arteries or their branches with the resultant symptoms.

5. Griserin.—Schomburg has tried this drug on twelve cases of tuberculosis. He says it exerts no influence upon the disease or upon the appetite and not infrequently causes irritation of the gastrointestinal tract.

6. Scurvy Among Nurslings.—Neumann says scurvy can follow the ingestion of raw milk heated no higher than 70° C., although a tendency of the children affected seems to exist. The author has seen fifty-nine cases since 1897, mostly among children who received milk from a certain dairy. It is important for parents to know whether or not the milk received has been previously warmed.

January 9, 1905.

1. Observations on the Cholera Epidemic in Southern Russia and Russian Middle Asia, By H. HAHN.
2. Nervous and Mental Diseases After Electrical Injuries (*To be concluded*), By A. EULENBURG.
3. Examination of Children in Connection with Behring's Theory of Tuberculosis Infection, By H. BEITZKE.
4. Aplastic, Lymphatic Leucæmia and Remissions in Leucæmia, By A. WOLFF.
5. The Function of the Labyrinth of the Ear (*Concluded*), By PASSOW.

4. Aplastic Leucæmia.—Wolff maintains that the leucocyte count in leucæmia is not as important a diagnostic factor as formerly. He says that the prognosis of a small leucocyte count is had when it is a sign of aplasia of the hæmatopoietic system. He claims that aplastic lymphatic leucæmia, a new clinical picture, is recognizable in life. In leucæmias, there are pseudoremissions characterized by lytic processes in the especially sensitive atypical young forms of leucocytes. Wolff reports a case of lymphatic leucæmia without an increase in leucocytes with an actual remission at present six weeks in duration.

5. Labyrinthine Functions.—Passow says that many of the symptoms accompanying labyrinthine disease are difficult to determine. Among these are the absence of the physiological nystagmus in turning movements, the absence of vertigo and the diminution of muscular tone. In the past year the author has seen a number of cases of middle ear disease with labyrinthine fistule, in eight of which he could demonstrate unilateral necrosis of the labyrinth.

6. Internal Treatment of Bladder Catarrh.—Posner says that in acute gonorrhœal inflammation of the bladder, local treatment is not indicated, and that the balsams are most helpful. Urotropin is most useful in catarrhs of non-tuberculous and non-gonorrhœal character, and the drugs proposed as substitutes for it, have no especial advantages. Turpentine often acts well in chronic cases.

ZENTRALBLATT FUER GYNAEKOLOGIE.

December 31, 1904.

1. A New Cystoscope Stand, By O. POLANO.
2. Total Inversion of the Uterus, By R. WANNER.
3. Histology and Pathogenesis of Chorioepithelioma Malignum, By T. BURDZINSKY.
4. A New Theory of Pelvimetry, By S. VON GASZYRSKI.

1. New Cystoscope Stand.—Polano describes a stand for the use of the cystoscope which has proved useful in the Würzburg clinic. The vesical picture can be fixed so that the observer has an opportunity of seeing it for as long a period of time as he desires.

2. Inversion of the Uterus.—Wanner reports two cases of total inversion of the uterus which were cured by extirpation. The first case developed while straining at stool fifteen days post partum. There was also a complete tear of the perinæum. In the second instance, an elderly woman sustained a prolapse while lifting a heavy load, the cause of the prolapse being a large sized pedunculated myoma.

3. Chorioepithelioma.—Burdzinsky has examined six cases of chorioepithelioma. His conclusions, much condensed, are that the neoplasm arises from the epithelial elements of the coverings of the chorionic villi and that the growth therefore always contains representatives of the two typical elements thereof. He found many mitoses in transition forms, in syncytial masses and in polynuclear protoplasmic masses, and concludes therefrom that the syncytium in chorioepithelioma is capable of dividing itself directly and indirectly. From other observations, he is convinced that the cells of Langhans arise from the syncytium, representing a later stage of development. The author also propounds a theory for the formation of metastases which is too lengthy to permit of abstraction.

January 14, 1905.

1. A Case of Primary Sarcoma of the Pelvic Cellular Tissue, By D. PULVERMACHER.
2. The Suboccipitofrontal Head Measurement, By J. KOCKS.
3. Stypticin in Uterine Hæmorrhages, By M. FREUND.
4. Anæmia and Local Anæsthesia, By B. MÜLLER.

1. Primary Sarcoma of Pelvic Cellular Tissue.—Pulvermacher reports the case of a woman with a tumor of the pelvis which proved, on laparotomy, to be a primary sarcoma of the pelvic cellular tissue. The patient succumbed, five months later, to a recurrence. The growth appeared to have started in the right broad ligament and was of the large, spindle celled variety. There were many metastases.

3. **Stypticin.**—Freund, who is responsible for the introduction of stypticin as a therapeutic measure, finds no advantage for the recently presented and similar preparation, styptol.

ZENTRALBLATT FUER INNERE MEDIZIN.

January 7, 1905.

1. Action of Subcutaneous Infusions of Sodium Chloride in Nephritis and a Consideration of the Newer Theories as to the Value of This Salt in Renal Diseases,

By LUIGI FERRANNINI.

1. **Sodium Chloride in Renal Diseases.**—Ferrannini concludes that the subcutaneous injection of sodium chloride in cases of nephritis, causes a temporary increase in albuminuria and in the renal elements found in the sediment. This increase is at once followed by a diminution with a limited, but certain, improvement in the general condition and the renal function. Even during a uræmic attack, copious subcutaneous and rectal injections of salt solution are not harmful, but are even beneficial, since they may aid the kidneys in their functions. On account, however, of their limited use and of the dangers of constant injections, salt solutions cannot be advised as a therapeutic measure. The injections may be of service, however, in emergency, as they have always been used.

ZENTRALBLATT FUER CHIRURGIE.

December 10, 1904.

1. Treatment of Tuberculous Ascites, By SCHOEMANN.
2. The Ambulant Treatment of Fractures of the Thigh, By S. KOFMANN.

1. **Tuberculous Ascites.**—Schoemann has used for some years the following treatment: He aspirates the abdomen with a trochar and a cannula of moderate size, allowing all the fluid possible to escape. He then injects into the abdominal cavity a sterilized emulsion of iodoform of a strength varying from 1 to 5 to 100 of glycerin. He begins with from 1 to 2 centigrammes of the one per cent. emulsion, and in from four to eight days he increases the strength. He found 3 or 4 injections sufficient to effect a cure. In 7 adults, a cure was brought about in from three to ten weeks, and in the cases of 2 children, the transudate ceased to form after the second injection. The author advises this method especially with patients in poor condition upon whom a laparotomy cannot be performed, and it can also be carried out on ambulant patients.

2. **Fractures of the Thigh.**—Kofmann advises the same method of treatment as Lorenz advocates after his method of reduction of congenital dislocation of the hip. Lorenz's pelvic support and a number of iron supports are necessary. The fracture is reduced under anaesthesia, a tricot covering is placed over the leg, and the whole extremity is abducted and rotated outwards. The crests of the ilium, the tuberosities of the ischium, and the patella are inclosed in plaster of Paris, the iron support for walking being included. Walking is allowed the next day and the author states that there are constant good results. To prevent injury to the soft parts at the site of the fracture, a window is left in the bandage.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

December 11, 1904.

1. A Case of Abdominal Aortitis, By ERCOLE GALVAGNI.
2. Amyloid Degeneration of the Kidneys and Spleen in a Case of Pharyngeal Diphtheria, By F. BELLINATO.
3. On the Origin of Cytoses, By C. MOLON.
4. Injections of Liquid Phenol in Anthrax, By DOMENICO SASSI.

By TITO DI GIUSEPPE.

4. **Treatment of Anthrax.**—The ordinary treatment of anthrax pustules which Sassi uses, is to make a crucial incision and to apply the thermocautery. This method has the approval of a great many surgeons. In some cases, however, the pustule does not yield to this treatment, and in such instances the method of Maffucci is usually tried—the injection of a two per cent. solution of carbolic acid into the carbuncle. Aside from being painful this method requires time and patience, and frequent repetition. Thus, one author reports that he made 108 injections within three days in a single case of anthrax. The author, therefore, prefers to use pure liquid carbolic acid which is always accessible, unlike the specific serum made by Selavo, which cannot be had everywhere when it is needed in a hurry. Injections of a strong solution of mercuric chloride have been used, but as yet their value has not been sufficiently well proved, and the pure carbolic acid is more convenient. The only possible drawback to the use of pure carbolic acid is the occasional occurrence of phenol poisoning. It is fortunate, however, that the organism which is infected with anthrax seems to offer a special resisting power against the toxic effects of carbolic acid, and therefore cases of phenol poisoning in such patients are very rare. The method employed by the author consists simply in the injection of five drops of carbolic acid into three parts of the carbuncles—i. e., fifteen drops in all, at one dose. This dose may be repeated again during the same day. In the case reported these two injections sufficed to lower the temperature and to bring about recovery within a short time.

December 18, 1904.

1. Contribution to the Study of Myoclonus, By NAPOLEONE SOMA.
2. A Case of Cyst of the Cervix Uteri, By CARMELO FERLITO.
3. Some Considerations on the Radical Cure of Inguinal Hernia, By TESEO CALDESI VALERI.
4. Contribution to the Surgical Treatment of Retrodisplacements of the Uterus, By FRANCESCO ORTA.
5. Herniae of the Falloppian Tubes, By CARLO CLERICI.

4. **Operative Treatment for Uterine Retrodisplacements.**—Orta reports successes with Foschi's operation of uterofixation. The technics employed is as follows: The patient being placed in the Trendelenburg position, a median incision is made suprapubically. The edges of the peritoneum are sutured to the skin on either side by a single stitch, the intestines are protected by means of pads, and the fundus is seized with two Museaux forceps. Buttonholes are next made in each rectus muscle about three quarters of a cm. away from the median line. These buttonholes pass through the entire thickness of the abdom-

inal wall, except the skin, and loops from the round ligaments are passed into them. These loops are held in place by means of forceps, while the peritonæum and the muscular layers of the abdomen are closed. The round ligaments having next been sufficiently drawn upon to secure the uterus in place, the loops are sutured into the buttonholes in the recti, the suture on each side passing through both edges of the buttonhole and through the two bends of the loop. The portions of the loop which then remain above the aponeurosis of the muscles are then freshened by scraping, and sutured directly upon the aponeurosis. The skin wound is finally closed. The buttonholes are best made by blunt dissection with the end of an artery forceps.

ROUSSKY VRATCH.

December 25, 1904.

- i. The Investigation of Illumination in Schools and the Use of Wingen's Photometer, By M. I. REICH.

1. **Illumination of Classrooms.**—Reich calls attention to the frequent deficiency in illumination which is still found in classrooms in the best schools of the large Russian cities. Accurate measurements of the illumination of these rooms and of the amount of light which falls on each pupil's desk are imperative, in order to satisfy the requirements of hygiene. The best instrument for this purpose which has thus far been devised is the photometer of Wingen, which recently received the approval of the Prussian Governments as a means of measuring the illumination of classrooms in that country. This instrument is simple in its method of employment, and is inexpensive, the price being only \$8.00, so that every school can afford one. The author describes in detail the method of using this new photometer. The standard illumination for a classroom should be fifty metrocandles, or "lucres." Anything below ten lucres, cannot be tolerated, but an illumination of from 30 to 40 lucres is still good. Direct daylight at a window measures a much larger amount, and even on cloudy days the photometer records 1,200 lucres sometimes. The amount of light in any part of a room diminishes very rapidly indeed with the distance from the windows.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

February 11, 1905.

1. Symptomatology, Pathology, and Treatment of Choreiform Movements, By WILLIAM G. SPILLER.
2. Convulsive Tic, By HUGH T. PATRICK.
3. Hysterical Movements, By HOWELL T. PERSHING.
4. The Radical Operation for Empyema of the Frontal Sinus, By W. FREUDENTHAL.
5. The Present Status of Antituberculosis Work in the United States. Suggestions for a More Effectual Cooperation of Authorities, Philanthropists, Physicians, and Laymen, By S. A. KNOPF.
6. The Association of Optic Neuritis and Facial Paralysis, By EDWARD A. SHUMWAY.
7. A Bacteriological Study of the Blank Cartridge, By DAVID H. DOLLEY.
8. The Present Status of Surgical Intervention in Retro-deviations of the Uterus, By LUCY WAITE.

9. Bloodless Perineal Prostatectomy Under Local Anæsthesia, By MARTIN B. TINKER.
10. Immunity. Chapters III and IV.

1, 2, and 3.—See this *Journal*, Vol. LXXIX, page 1256.

4. **Chronic Frontal Sinus Disease.**—Freudenthal devotes his paper almost exclusively to the consideration of chronic frontal sinus disease. By far the greatest number of patients suffering from this affection improve under intranasal treatment. A certain number of patients, however, are best treated by radical surgical methods. It is to this type of cases that the author devotes most of his space. The paper ends with the following general conclusions: "(1) Regarding the conservative treatment of these cases, the remarks made by A. Kuttner, of Berlin, are much to the point. Every one of us ought to try to live up to this conservatism as much as feasible. (2) In those cases in which we have to operate, Killian's method seems at present to give the best results. (3) The first opening into the frontal sinus must always be made below the outlined bridge, and only after exploring the sinus should another above it be made. (4) In the latter case we leave a bony bridge which helps toward improving the cosmetic effect. (5) Closing of the external wound immediately after the operation is by far preferable for such cosmetic effect."

5. **Tuberculosis.**—Knopf gives a bird's eye view of the work that has been done in the past two years for the control of tuberculosis in the United States and Canada. The paper contains a large amount of information that will prove valuable for reference. There are lists of societies and committees for the prevention of tuberculosis, of State commissions, of sanatoria, of special hospitals, and camps for the treatment of pulmonary tuberculosis and of dispensaries and clinics for the special treatment of this disease. The information is classified according to States. The paper closes with a strong plea for a more effectual cooperation between the existing institutions and for the formation of a United States Board of Health.

6. **Optic Neuritis.**—Shumway concludes: (1) Optic neuritis is occasionally associated with facial paralysis, either alone or as part of a multiple neuritis; the ætiological factor may be rheumatism, but at times appears to be an infection, the nature of which is as yet undetermined. The optic neuritis is usually of the retrobulbar type, but a decided papillitis may be present, and be followed by more or less marked atrophy. In cases of multiple neuritis, of the cranial nerves, the eyegrounds should be examined for possible optic nerve complication. (2) In facial paralysis, flattening of the face and enophthalmus may appear, and are to be considered as due to a neuritis of the fifth nerve, and not to involvement of possible sensory fibres in the facial nerve.

7. **The Bacteriology of Blank Cartridges.**—Dolley has studied blank cartridges of a number of the principal manufacturers to determine the

kind of bacteria they may contain. His conclusions follow: "(1) *aerogenes capsulatus* (Welch) was present in a large proportion of the wads of the three makes of cartridges examined. (2) The wads of the Peters Company, inoculated in rats, guinea pigs, and rabbits, produced characteristic symptoms of tetanus. (3) The powder of the three varieties of cartridges examined was negative for *B. tetani* and *B. aerogenes capsulatus*. (4) My efforts at isolation of *B. tetani* from the wads have so far been unsuccessful. (5) There is abundant evidence, from clinical observations and animal experiments, that the wads of certain blank cartridges contain *B. tetani*. Dr. Welch told me that he considered it diagnostic to see an animal in convulsions."

8. Surgical Intervention in Retrodeviations of the Uterus.—Waite condemns without reservation any and all operations for retrodisplacement of the uterus. The author states that such operations are unnecessary, unsafe, and have not had successful results sufficiently often to warrant their continued use.

9. Perineal Prostatectomy.—Tinker reports one case of perineal prostatectomy performed under local anesthesia. The patient recovered and suffered not at all. At one point of the operation he received a little ether. The author describes in detail his technics.

February 9, 1905.

1. A Case of Chylous Cyst of the Abdomen,
By MAURICE H. RICHARDSON.
2. The Active Treatment of Gonorrhœa in Its Early Stages,
By FREDERIC J. COTTON.
3. Glycosuria in Pregnancy,
By JAMES MARSH JACKSON and JAMES R. TORBERT.
4. I. K. I. Method of Sterilizing Catgut,
By F. W. JOHNSON.

1. Chylous Cyst.—Richardson's case simulated clinically tuberculous peritonitis. At operation a retroperitoneal chylous cyst was found, and it was removed without much difficulty. An anatomical explanation for the occurrence of the cyst could not be determined. The case is interesting from two points of view: (1) On account of the rarity of the condition; (2) on account of the original mistaken diagnosis. The author emphasizes the fact that human judgment is fallible and that while it is true that exploratory operation for the sake of diagnosis should not be resorted to, yet it is not safe to condemn a patient on the strength of a simple opinion that his condition is necessarily fatal.

2. Gonorrhœa.—Cotton believes that all cases of early acute gonorrhœa except in the presence of some contraindication (such as phimosis or acute folliculitis) do better under active irrigation which in itself much reduces the severity of the disease, and that the "organic" silver preparations in combination with profuse bland irrigations accomplish definite results by germicidal action. By following out a routine based on this, varied to suit varying cases, we can effect a very

rapid cure in a certain proportion of cases, a very considerable diminution of time of treatment required in the other cases, a very comfortable condition as to symptoms during the course of treatment and, by no means least, the most efficient limitation as yet possible of the area involved as well as of the duration, and hence the best chance for avoidance of complications and chronic processes.

3. Glycosuria in Pregnancy.—Jackson and Torbert, through the courtesy of colleagues, are able to report three cases of glycosuria which occurred during pregnancy. Two of the patients were sugar free after delivery. One died a few hours after her child was born. Temporary glycosuria is not infrequent during the last months of pregnancy. The specific gravity of the urine is not necessarily high under such conditions. If the glycosuric pregnant woman shows other signs of diabetes the uterus should be promptly emptied. However, on account of the liability of sudden collapse, the use of anesthetics should be avoided as far as possible.

4. Claudius Catgut.—Johnson has used iodine catgut for the past year, and is enthusiastic as to its good qualities. It should not be used in the vagina, as it is too irritating for mucous membranes. The author reports a number of laboratory tests which go to show that when catgut is properly prepared by this method it is not only aseptic, but markedly antiseptic.

MEDICAL RECORD.

February 11, 1905.

1. The Attractive Features of Graduated Tenotomies Upon the Eye Muscles,
By AMBROSE L. RANNEY.
2. On Some Relations of Medicine and Surgery to Jurisprudence,
By CARL BECK.
3. Choice of a General Anæsthetic and Selection of Method of Administration,
By VICTOR C. PEDERSEN.
4. Cryoscopy of Cerebrospinal Fluid in Epidemic Cerebrospinal Meningitis,
By JOHN H. BAILEY.
5. Foreign Body in the Bronchus; Removal with the Aid of the Bronchoscope; Recovery,
By SIDNEY YANKAUER.
6. A Spindle Cell Sarcoma of the Bowels Operated on Successfully,
By J. B. BOUCHER.

1. Graduated Tenotomies.—Ranney asserts that the clinical histories of the twenty selected cases which he now reports demonstrate beyond cavil or dispute that rapid and permanent cures of many forms of nervous derangements which had no apparent connection with eye strain and which had proven to be incurable by drugs have been effected through the surgical relief of eye strain. A list of the cases cured by the author by means of graduated tenotomies follows: Asthenopia; epiphora; extreme deformity from wry neck; insanity; chorea, followed by paralysis; progressive atrophy of muscles in both hands with partial loss of the use of the right hand and diabetes of some years' standing; complete loss of intellectual faculties; uncontrollable attacks of vomiting, loss of power and sensation in both arms, and suspected tuberculosis; of each one case; nervous prostration, two cases; sleepless-

ness and nervous prostration, two cases; uncontrollable neuralgia, three cases; epilepsy, five cases. The paper ends with twenty-one formal conclusions.

4. **Cryoscopy.**—Bailey's study of the cerebrospinal fluid in meningitis by the aid of cryoscopy has not been productive of any results available at present for positive practical purposes. The data he has accumulated are published, on account of their possible future value.

5. **Bronchoscopy.**—Yankauer reports this case: Child, ten months old, suffering from an orange pit lodged in right bronchus. Low tracheotomy and bronchoscopy through the opening, and removal of the pit by long forceps. Recovery.

6. **Sarcoma of the Bowel.**—Boucher reports this case: Woman, aged thirty-eight years. Sarcoma of cæcal end of small bowel and of ascending colon. Resection of six inches of small intestine, of all the ascending colon and of half of the transverse. Lateral anastomosis. Recovery. Patient living one year after operation with apparently no recurrence of the sarcoma.

MEDICAL NEWS.

February 11, 1905.

1. Report of a Sporadic Outbreak of Typhoid Fever at Lawrence, N. Y., Due to Oysters,
By GEORGE A. SOPER.
2. Hæmaturia as a Symptom of Hydronephrosis. Nephrectomy. Cure,
By L. BOLTON BANGS.
3. Two Cases of Tracheal Stenosis from New Growth,
By GEORGE EMERSON BREWER.
4. The Management of Acute General Peritonitis,
By J. GARLAND SHERRILL.
5. The Clinical Manifestations of Uterine Fibroids as Indications for Early Operative Intervention,
By ARNOLD STURMDORF.

1. **Typhoid Due to Oysters.**—Soper's paper is the formal report he presented to the Board of Health of the village of Lawrence, N. Y., after his investigation of an outbreak of typhoid which occurred during the past summer and fall. In all, thirty-one patients acquired typhoid. Of these cases twenty-five are, according to the author, directly traceable either to infected oysters and clams, to contact with typhoid patients or to bathing in the water near the oyster floats. Six cases acquired the disease in some unknown way. The author notes that the special importance of his observations is due to the fact that it has been denied, on reputable authority, that oysters are capable of transmitting typhoid fever.

2. **Hæmaturia in Hydronephrosis.**—Bangs reports in great detail a case of hydronephrosis which presented hæmaturia as one of its symptoms. An exhaustive search of recent medical literature shows that the occurrence is rare. Thirteen similar cases have been reported, nine of them by Israel.

3. **Tracheal Stenosis.**—Brewer reports in detail the two following cases: (1) Papilloma of the trachea following tracheotomy for the relief of

papillomatous degeneration of the laryngeal mucous membrane. (2) Adenocarcinoma of an accessory thyreoid gland causing marked tracheal stenosis.

4. **Acute General Peritonitis.**—Sherrill divides acute general peritonitis into (1) acute septic and (2) acute suppurative. The former is generally fatal whatever treatment is employed. Yet a certain number of cases recover. At times medicinal treatment will give the best results, at times surgical intervention is advisable. Each case must be treated on its merits and general rules cannot be laid down. The bulk of the paper is devoted to the treatment of acute suppurative peritonitis. If the patient refuses surgical intervention or if the patient's condition does not warrant an operation, three methods of treatment may be adopted: (a) The opium treatment as advocated by Alonzo Clark; (b) the treatment by salines (Tait); (3) the rest treatment (Ochsner). It is an open question which of these methods is the best. If operation is resorted to the special measures to be taken will depend on the nature of the disease giving rise to the suppuration. So far as the general peritoneal cavity is concerned there are three plans of treatment: (a) Simple drainage; (b) wiping the cavity as clean as possible; (c) irrigation. The author adopts the last plan.

5. **Uterine Fibroids.**—Sturmdorf reviews the clinical history of uterine fibroids, and concludes that excision is the only rational mode of treatment.

AMERICAN MEDICINE.

February 11, 1905.

1. Some Forms of Insanity Due to Alcohol, Especially in Their Medicolegal Relations, By CHARLES K. MILLS.
2. The History and Development of Surgery During the Past Century (*To be concluded*),
By FREDERIC S. DENNIS.
3. A Short Note on Subcutaneous Alimentation,
By ARTHUR E. BARKER.
4. Bezold's Variety of Mastoid Disease, Complicating Diabetes Mellitus,
By S. MACCUEEN SMITH.
5. Pneumonia and Pregnancy. By ROBERT C. RAMSDALL.
6. Typhoid Coxitis, with Report of a Case,
By JOHN L. PORTER.

3. **Subcutaneous Alimentation.**—Barker has used subcutaneous alimentation for a number of years and, in suitable cases, has found it of considerable service. His experience has been chiefly with surgical cases. At present this method of administering nourishment is still in its infancy. His experience has been chiefly with isotonic salt and sugar solutions and with olive oil. With the latter substance his experience has been very limited. (1) Normal salt solution. This is used mostly for furnishing fluid to the tissues. A nine tenths of one per cent. solution is advised. It may be given either subcutaneously or intravenously. (2) Isotonic sugar solution. This is given for its food value. A five per cent. solution is isotonic to the blood. It should be given subcutaneously, best, at the inner side of the arm near the axilla. The total quantity to be used

at each injection is not given. (3) Sterile olive oil, while theoretically of high potential food value, is probably not very efficacious, as it is absorbed very slowly.

4. **Mastoid Disease.**—Smith summarizes his conclusions thus: "(1) Aural complications of diabetes mellitus may originate primarily in the mastoid cells. (2) The process may be manifested by the classic mastoid symptoms without involving the tympanic cavity. (3) This condition is peculiar to diabetes mellitus. (4) The term 'diabetic ear' should be limited to those cases in which the disease begins as a primary osteitis of the mastoid, or in which primary tympanic involvement and rapid mastoid complications seem simultaneous. (5) It is advisable to reduce the amount of sugar when possible before operating in those cases showing an excessive glycosuria, unless the urgency of the local symptoms demand immediate operation."

5. **Pneumonia and Pregnancy.**—Ramsdell summarizes his observations as to the influence of pregnancy on pneumonia thus: (1) The death rate is appreciably higher in the pregnant woman than in the ordinary patient. (2) Abortion takes place in more than half the patients. (3) The mortality is much higher when abortion takes place than when the uterus does not empty itself. (4) The mortality is higher in the last three months of pregnancy. (5) The causes of death can be attributed to: (a) Diminution in hemoglobin; (b) degenerative changes in heart muscle; (c) overloading of the right heart and pulmonary circulation after birth. (6) The high percentage of abortions is due to accumulation of carbonic acid in the blood.

6. **Typhoid Coxitis.**—Porter reports a case of double coxitis due to typhoid. The symptomatology of the condition is briefly reviewed and the tendency to spontaneous dislocation noted. In the case reported spontaneous evacuation of the joint occurred on one side. This side did not become dislocated, and when recovery finally occurred there was little impairment of motion. The opposite joint suffered considerable destruction, and ultimate deformity was so great that operation had to be resorted to to straighten the leg. Very limited motion now exists in this joint. The moral would seem to be that incision and drainage are the proper treatment for typhoid coxitis.

7. Chronic Suppurative Otitis Media: the Necessity for Early, Systematic, and Energetic Treatment, By H. SMURTEWAITE.
8. The Treatment of Postnasal Adenoids, By J. W. COUSINS.

1. **Dysphagia.**—Collier reports a case of oesophageal stricture with dysphagia and discusses the condition. Diagnosis. Dysphagia is not always due to stricture of the oesophagus, and before passing a bougie the following conditions should be sought for and eliminated: 1. Morbid conditions of the mouth or pharynx. (a) Bad teeth. (b) Tumors, abscess, or other affections of the tonsils. (c) Tumors or cysts of the urula, pharynx, or postnasal spaces. (d) Postdiphtherial paralysis of palate or pharynx. (e) Glosso-labiopharyngeal palsy. 2. Morbid conditions of the larynx. Tuberculous or malignant disease of the larynx, or oedema of the glottis, may produce marked and profound dysphagia. 3. Tumors in the neck outside the oesophagus. A cyst or tumor of the thyroid gland may cause dysphagia by pressure. 4. Aneurysm may give rise to dysphagia by pressing on the oesophagus. The accompanying dyspnoea may arise from direct pressure on the trachea, pressure on the bronchus, the lung, the recurrent laryngeal nerve, or the pulmonary vein. 5. Intrathoracic tumors, such as enlarged tuberculous glands, cancerous and other tumors, or abscesses in the posterior mediastinum, may compress the oesophagus: the same is true of local empyemata. 6. Dislocation of the sternal end of the clavicle backwards may be a cause of dysphagia. 7. Impaction of a foreign body in the gullet. When these conditions have been excluded the bougie may be passed. An anæsthetic is often desirable in these cases. If there be a stricture, if syphilis, traumatism, and corrosive poisons can be excluded, and if there has been wasting, the diagnosis of malignant disease is justified. The best operation in these cases is Albert's modification of gastrostomy, by which a conical diverticulum of the stomach is made to open above the front and on the level of the costal cartilages. Around the base of the diverticulum are sutured the parietal peritoneum and the posterior layer of the sheath of the rectus. As a result the diverticulum is drawn upwards; its base is gripped by the muscular fibres of the rectus, while a short upward directed subcutaneous oesophagus is also formed. All escape of fluid is thus prevented, and the patient can be safely fed at once.

3, 4, 5. **Nasal Disease.**—Moritz discusses the diseases of the nasal accessory ("adnasal") cavities, and their relation to general diseases. Syphilis is a frequent cause of such diseases, while tuberculosis is rare. Acute coryza and influenza, due to infectious organisms, are the most frequent causes, the infection being carried directly from the mucous membrane of the nose. Croupous pneumonia, and the exanthemata also give rise to diseases of the adnasal cavities. In cerebrospinal

meningitis the meningococcus is present in the adnasal cavities in every case. The adnasal cavities may also be invaded by tumors, or inflamed as a result of traumatism. The most frequent symptom is headache: this may be neuralgic, diffuse, or hemicranic in character, and is usually relieved by phenacetin. An irregular fever occurs, due to absorption or retention of pus. Neurasthenic symptoms, such as flushing, lassitude, etc., are not at all rare. The author does not think that there is any very intimate connection between adnasal disease and asthma. Gastric symptoms, due to swallowing of pus, are common. The diagnosis can only be established by a thorough rhinoscopic examination, including anterior and posterior rhinoscopy, and if necessary, the use of the probe, aspiratory trocar, transillumination, Röntgen ray examination, etc. The eye symptoms most frequently connected with adnasal diseases are obstruction of the lacrymal duct with epiphora, conjunctivitis, and œdema or inflammatory swelling of the eyelids. Empyemata of the frontal and ethmoid sinus occasionally perforate towards the orbit. Sudden loss of vision through compression of the optic nerve in the foramen opticum or by perineuritis, or exophthalmos through serous or purulent infiltration. The exophthalmos comes and goes and is usually combined with some paralysis of the eyeball muscles. Meningitis, cerebral abscess, and sinus thrombosis are happily rare.

Bronner's subject is the same as that of Moritz. He is strongly opposed to indiscriminate removal of sœptum spurs and deviations. But he does think that the nares should be most carefully examined, and if necessary treated, in all cases of asthma, hay fever, laryngitis, bronchitis, deafness, headache, gastritis, nasal obstruction, or nasal discharge.

Whitehead considers the subject of headache in connection with nasal disease. His conclusions are: 1. Nasal disease is undoubtedly the cause of headaches in a certain number of cases; but only where there is discharge or abnormal nasal respiration. 2. In all cases of persistent headache examination of the nose should be a routine practice. 3. Suppuration in the accessory sinuses and marked nasal obstruction should be thoroughly treated. 4. Small spurs and deviations should be left alone. 5. If the middle turbinates are enlarged and pressing upon the sœptum, especially upon the tubercle, and if all other possible causes of headache have been eliminated, partial removal of the hypertrophied bone should be advised, since in many such cases complete relief is given.

6. Rhinitis Caseosa.—Edmunds reports a case of this interesting condition, in which the material removed was a putty-like material with a very offensive faecal smell. It was yellowish in color, but contained practically no fat. The microscope showed it to consist of crystals of calcium phosphate imbedded in a granular mass of detritus. The author suggests that its formation is similar to that of the calculi containing calcium compounds and cholesterol found in chronic catarrh of the gall bladder.

8. A Case of Septate Uterus and Vagina; Pregnancy in the Right Half; Delivery, By C. A. LANE.
9. Army Medical Organization in Bavaria, By F. HOWARD.

1. Richter's Hernia.—Low reports four cases of Richter's hernia, which consists in a strangulation of part only of the circumference of the gut wall, the area involved varying from a quarter, or even less, up to two thirds or three quarters of the circumference. Where the larger portion of the wall is involved the remainder of the lumen is usually occluded by the kinking of the coil of intestine. It is almost invariably the small intestine which is involved, generally the ileum, and the area of gut wall strangulated is that opposite the mesenteric border. It occurs more frequently in women and in femoral herniæ; it only occurs in adults and is more common on the right side. All of the four cases here reported were women with right sided femoral herniæ. The symptoms are at first milder than in ordinary strangulated hernia, the vomiting being less severe and rarely faecal, and the bowels may be open throughout, diarrhoea being sometimes present. The hernial protrusion may escape notice, and gangrene of the strangulated area is common. Cases of spontaneous cure occasionally occur with the formation of a faecal fistula which later closes of itself. Of the author's four patients all were operated upon, two dying. Early and correct diagnosis is imperative. The protrusion is frequently mistaken for an inflamed gland. The operation is merely that for any other strangulated hernia. In the event of perforation or gangrene the intestine falls back into the abdominal cavity and general peritonitis ensues.

2. Myelopathic Albumosuria.—Moffatt reports a case of this rare affection, and gives a general account of the disease. It is characterized by the presence in the urine of a peculiar proteid body associated with pathological changes in the bone marrow. So far thirty-nine cases have been reported, Bence Jones being the first to do so. Naturally it has been asked whether this disease and multiple myeloma are causally related: the author holds that multiple myeloma occurs without even intermittent Bence Jones albumosuria, but that the albumosuria is always associated

with disease of the bone marrow. The appearance of albumose in the urine is always of fatal import. The symptoms of myelopathic albumosuria are general pains, increasing weakness, and anæmia, and progression to a fatal end. Spontaneous fractures of the ribs, and bony tumors and deformities are often noted. Nothing is known as to its ætiology. Most of the cases prove fatal within a year, death being due to exhaustion, pneumonia, etc. There is no treatment. The pathological changes are practically confined to the skeleton, the ribs, sternum, and vertebral bodies being always affected. The new growth is gelatinous, soft, and vascular, and is composed chiefly of round cells with little intercellular substance, being apparently closely allied to sarcoma. *Urine.* The only constant peculiarity is the presence of albumose. This proteid coagulates at 58° C., much lower than serum albumin. On further heating to boiling the precipitate dissolves, to reappear on cooling. If albumose is abundant a dense precipitate is obtained with strong hydrochloric acid: the "ring" method may be used where the quantity is small. Albumose is also precipitated by strong nitric acid and by ferrocyanide of potassium and acetic acid. In conclusion, the author gives a careful report of his own case.

4. **Parasite of Carcinoma.**—Robertson and Wade have investigated the validity of the hypothesis that carcinoma is dependent upon the growth of a parasite of the same class as the plasmiodiophora brassicæ which is known to cause tumor growths in various members of the crucifera, as well as in other plants. They claim to have succeeded in demonstrating the presence in carcinomatous tumors of bodies corresponding in form and reaction to a special method to fourteen phases in the developmental cycle of the plasmiodiophora brassicæ, and also in growing from such tumors an organism which accurately represents several successive phases of a parasite of this class. The staining process used is the ammoniosilver method: the tissues after being hardened in formalin are impregnated with silver, and the sections are toned with gold, platinum, and palladium. The technics of cultivating the organism consists in placing pieces of the fresh tissue upon the dry surface of an agar medium; the surface must be quite dry, and the tissue fresh and unchilled.

5. **Paraffin Injection.**—Wallis reports two cases illustrating the possible aftereffects of paraffin injection. In one case the injection had been made into the broad ligament two years previously for prolapse of the uterus. At the operation an abscess was found to have formed and forty ounces of inodorous pus, together with lumps and masses of paraffin removed. In the second case injection had been performed for prolapse of the rectum: six weeks later a sudden discharge of paraffin occurred, and a sinus set up.

6. **Cerebral Hæmorrhage.**—Russell has studied the relation between various atmospheric conditions and the occurrence of cerebral hæmorrhage. He concludes that there seems to be a

slight tendency towards the occurrence of cerebral hæmorrhage on days of high atmospheric pressure and also on days of rising pressure, the former being probably the important factor. There is a very marked tendency on days of low wind pressure and the combination of a low wind pressure with a high barometric pressure is the condition under which the largest number of cases took place. Apart from season, temperature in itself has not been shown to exert any influence, though a small excess of cases has been noted on days with a rising thermometer and also with a combined rise of atmospheric pressure and temperature.

New Inventions.

DR. JANEWAY'S PORTABLE SPHYGMOMANOMETER.

The value of an accurate knowledge of the blood pressure of the patient can hardly be overestimated in studying the various forms of heart disease, pneumonia, Bright's disease, tuberculosis, emphysema, typhoid fever, diabetes, etc. By use of the apparatus invented by Dr. Theodore C. Janeway it is possible for the physician to determine readily both the systolic and diastolic pressure.

This form of sphygmomanometer, which is illustrated herewith, is of special value on account

Dr. Janeway's sphygmomanometer.

of its portability, the ease with which it is applied, and the accuracy with which observations may be made by its use.

Dr. Janeway states¹ that he was driven to the construction of this apparatus by the fact that he could not obtain a sphygmomanometer which combined all the features of the instrument as perfected by him in a portable form. It is highly essential that the calibre of the tubing be large enough to allow satisfactory transmission of the pulse wave and the estimation of diastolic pressure.

The accompanying illustration gives a fair idea of the device as made under the direction of Dr. Janeway, by Charles E. Dressler & Brother, 143 East Twenty-third Street, New York, to whom he acknowledges his indebtedness in overcoming the mechanical difficulties presented in the manu-

¹ *Medical News*, August 27, 1904.

facture of the apparatus. The instrument is not only ingenious in design, but is well made and very durable, and its applications are made perfectly clear by means of explanatory circulars furnished with the apparatus.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from February 3 to February 11, 1905:

Smallpox—United States.

Place.	Date.	Cases.	Deaths.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending February 8, 1905:

BELL, J. M., Pharmacist. Upon being relieved from duty at St. Louis, Mo., by Pharmacist G. A. Morris, to proceed to Fort Stanton, N. M., and report to the Medical Officer in Command for duty and assignment to quarters. February 4, 1905.

DUFFY, F., Acting Assistant Surgeon. Granted leave of absence for seven days from February 8th.

FRANCIS, EDWARD, Assistant Surgeon. Granted leave of absence for seven days from February 2, 1905, under paragraph 191 of the regulations. Granted extension of leave of absence for twenty-three days from February 9th.

GASSAWAY, J. M., Surgeon. Granted leave of absence for ten days from February 9th.

HARGIS, J. W., Acting Assistant Surgeon. Granted leave of absence for twenty days from February 8th.

LINLEY, W. J., Acting Assistant Surgeon. Granted leave of absence for thirty days from February 13th.

MCCONNELL, E. F., Acting Assistant Surgeon. Granted leave of absence for thirty days from February 1st.

MORRIS, G. A., Pharmacist. Relieved from duty at Fort Stanton, N. M., and directed to proceed to St. Louis, Mo., and report to the Medical Officer in Command for duty and assignment to quarters, relieving Pharmacist J. M. Bell. February 4, 1905.

RICHARDSON, T. F., Passed Assistant Surgeon. To proceed to Savannah Quarantine and assume temporary charge of the service during the absence, on leave, of Acting Assistant Surgeon W. J. Linley. February 2, 1905.

WILSON, R. L., Passed Assistant Surgeon. Granted leave of absence for one month from March 1st.

Board Convened.

Board convened to meet at the Marine Hospital, Baltimore, Md., February 3, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon C. W. WILLE, chairman. Acting Assistant Surgeon G. H. STEUART, recorder.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending February 11, 1905:

BAKER, DAVID, First Lieutenant and Assistant Surgeon. Ordered to accompany the Sixth Infantry from Fort Leavenworth, Kan., to San Francisco, Cal.

BANISTER, WILLIAM B., Major and Surgeon. Ordered to accompany the Second Squadron, Eighth Cavalry, from Jefferson Barracks, Mo., to San Francisco, Cal., and then return to proper station.

BUCK, CARROLL D., First Lieutenant and Assistant Surgeon. Ordered to accompany the Sixth Infantry from Fort Leavenworth, Kan., to San Francisco, Cal.

JEAN, GEORGE W., First Lieutenant and Assistant Surgeon. Granted two months' leave of absence.

LITTLE, WILLIAM L., First Lieutenant and Assistant Surgeon. Ordered to proceed from Fort Oglethorpe, Ga., to Jackson Barracks, La., for duty.

MATHEWS, GEORGE W., First Lieutenant and Assistant Surgeon. Retired as captain, to date from February 2, 1905.

SMART, ROBERT, First Lieutenant and Assistant Surgeon. Ordered to proceed from Fort Du Pont, Del., to Fort Myer, Va., for duty.

THOMASON, HENRY D., First Lieutenant and Assistant Surgeon. Ordered to report to Lieutenant Colonel George H. Torney, Deputy Surgeon General, General Hospital, Presidio of San Francisco, Cal., for examination for promotion, not later than March 3, 1905.

THORNBURGH, R. M., First Lieutenant and Assistant Surgeon. Granted ten days' leave of absence, to date from February 7, 1905.

TORNEY, GEORGE H., Lieutenant Colonel and Deputy Surgeon General. Reports in temporary charge of the Chief Surgeon's Office, Department of California.

WILSON, JAMES S., Captain and Assistant Surgeon. Ordered to proceed from Fort Myer, Va., to Fort Oglethorpe, Ga., for duty.

WINN, ROBERT N., First Lieutenant and Assistant Surgeon. Ordered to report to Lieutenant Colonel George H. Torney, Deputy Surgeon General, General Hospital, Presidio of San Francisco, Cal., for examination for promotion, not later than March 3, 1905.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 11, 1905:

BARBER, G. H., Surgeon. Detached from the Naval Training Station, Newport, R. I., and ordered to the *Ohio* on February 25, 1905.

BISHOP, L. W., Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to continue duties at the Navy Yard, New York, N. Y.

BLUE, J. H., Assistant Surgeon. Appointed an assistant surgeon, with the rank of lieutenant, junior grade, from January 16, 1905.

DE VALIN, C. M., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from January 31, 1905.

DRAKE, N. H., Medical Inspector. Commissioned a medical inspector, with the rank of captain, from January 1, 1905.

ELMORE, B., Acting Assistant Surgeon. Ordered to the Navy Yard, Washington, D. C., for duty at the Naval Hospital.

FOSTER, T. G., Assistant Surgeon. Appointed an assistant surgeon, with the rank of lieutenant, junior grade, from January 16, 1905.

GRUNWELL, A. G., Surgeon. When discharged from treatment at the Naval Hospital, New York, N. Y., ordered to duty at that hospital.

GUEST, M. S., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from January 20, 1905.

HARMON, G. E. H., Medical Director. Commissioned a medical director, with the rank of captain, from December 15, 1904.

HIBBETT, C. H., Medical Inspector. Commissioned a medical inspector, with the rank of commander, from December 15, 1904.

HIGH, W. E. G., Assistant Surgeon. Detached from duty with the Marine Detachment, Midway Island, and ordered to the Naval Training Station, San Francisco, Cal.

ODELL, H. E., Passed Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the *Galveston*.

PLUMMER, R. W., Passed Assistant Surgeon. Ordered to the Navy Yard, Charleston, S. C.

STIEPP, J., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, with the rank of lieutenant, from June 7, 1904.

TYREE, F. W., Acting Assistant Surgeon. Detached from the Navy Yard, Charleston, S. C., and ordered to duty with the Marine Detachment on Midway Island.

VON WEDEKIND, L. L., Surgeon. Ordered to the Naval Training Station, Newport, R. I., with additional duty on board the *Constellation*.

WELLS, H., Medical Director. Commissioned a medical director, with the rank of captain, from January 1, 1905.

Births, Marriages and Deaths.

Married.

COLLINS—DAVIS.—In London, England, on Wednesday, February 8th, Dr. Joseph Collins, of New York, and Miss Edith Davies, daughter of Dr. W. M. Davies.

HARVEY—GALLATIN.—In San Francisco, California, on Wednesday, February 1st, Dr. William P. Harvey and Miss Lita Gallatin.

KENNER—FEREBEE.—In Oxford, North Carolina, on Wednesday, February 1st, Dr. Beverley Randolph Kenner and Miss Ruth Alexander Ferebee, daughter of Dr. N. McP. Ferebee, United States Navy.

KORNDORFER—JONES.—In Philadelphia, on Wednesday, February 1st, Dr. Augustus Korndorfer and Miss Mary M. Jones.

PALMER—McCANN.—In Louisville, Kentucky, on Monday, February 6th, Dr. E. R. Palmer and Miss Mary McCann.

WENDELBOE—SCHRAM.—In Rome, N. Y., on Thursday, February 9th, Dr. L. Thomas Wendelboe and Miss Viola Ella Schram.

Died.

ASKEW.—In Harrellsville, North Carolina, on Wednesday, February 1st, Dr. A. H. Askew, in the sixty-second year of his age.

BARTLETT.—In Thomasville, Georgia, on Friday, February 3rd, Dr. Homer L. Bartlett, of Brooklyn, N. Y., in the seventy-fifth year of his age.

DONLAN.—In Fitchburg, Massachusetts, on Thursday, January 26th, Dr. John M. Donlan, in the thirtieth year of his age.

FAUGHT.—In Philadelphia, on Thursday, January 26th, Dr. George C. Faught, in the forty-third year of his age.

FREER.—In Washington, D. C., on Monday, February 6th, Dr. James A. Freer, in the forty-seventh year of his age.

HALL.—In Granville, N. Y., on Friday, January 13th, Dr. Storrs Hall, in the ninety-first year of his age.

HENDRIX.—In St. Louis, Missouri, on Saturday, January 28th, Dr. Henry F. Hendrix, in the sixty-third year of his age.

JEFFERSON.—In Goldenpond, Kentucky, on Thursday, January 26th, Dr. Thomas B. Jefferson.

JOHNSTON.—In St. Louis, Missouri, on Tuesday, January 31st, Dr. William Johnston, in the ninety-second year of his age.

JONES.—In Brooklyn, Michigan, on Monday, January 30th, Dr. L. M. Jones, in the eighty-third year of his age.

PRESTON.—In Buffalo, N. Y., on Saturday, February 4th, Dr. Joseph Beach Preston, in the sixty-first year of his age.

RISK.—In Summit, New Jersey, on Tuesday, February 7th, Dr. William H. Risk, in the sixty-third year of his age.

SHORE.—In St. Louis, Missouri, on Monday, January 30th, Dr. John Shore, in the eighty-sixth year of his age.

SMITH.—In St. Louis, Missouri on Friday, February 3rd, Dr. Augusta Smith, in the seventy-fourth year of her age.

SPOONER.—In Utica, N. Y., on Monday, January 30th, Dr. Fred Spooner, of Sherburne, in the thirty-ninth year of his age.

STIGLEMAN.—In Floyd, Virginia, on Tuesday, January 31st, Dr. C. M. Stigleman, in the seventy-fifth year of his age.

STRONG.—In Fishkill Landing, N. Y., on Thursday, January 26th, Dr. Walter Day Otis Kellogg Strong, in the eighty-second year of his age.

THAYER.—In Hamilton, Massachusetts, on Sunday, February 5th, Dr. Samuel E. Thayer, in the sixty-third year of his age.

WILSON.—In Glenarm, Maryland, on Thursday, February 2nd, Dr. William W. Wilson, in the seventy-ninth year of his age.

YOUNG.—In Buffalo, N. Y., on Monday, February 6th, Dr. Edson H. Young, in the forty-fifth year of his age.

Original Communications.

RESECTION OF TWENTY-THREE INCHES OF GANGRENOUS INTESTINE DUE TO A VOLVULUS FOLLOWING A SECOND ATTACK OF APPENDICITIS. REPORT OF THIRTY-THREE CASES OF INTESTINAL OBSTRUCTION CAUSED BY UNOPERATED APPENDICITIS.*

By CLARENCE A. McWILLIAMS, M. D.,
NEW YORK,

INSTRUCTOR IN SURGERY, COLUMBIA UNIVERSITY; SURGEON TO
TRINITY HOSPITAL; ASSISTANT SURGEON TO THE
PRESBYTERIAN HOSPITAL.

In the *Medical News* of September 3 and 10, 1904, I published a report of eighty-six cases of intestinal obstruction subsequent to operations for appendicitis. I wish now to supplement that article by reporting cases of obstruction which follow attacks of appendicitis which had not been operated upon, believing that this condition is not fully recognized as it should be by the general practitioner, who is the one to see these cases first, and upon whose right judgment the future well being and life of the patient absolutely depend. As the following cases will amply testify, in the majority the right diagnosis has not been made sufficiently early to offer to the patient the prospects of a successful outcome to an operative procedure, which in itself alone could bring recovery. The surgeon is thereby much handicapped and surgery is brought into disrepute.

The cases may be divided into acute and chronic, and these terms refer to the suddenness and rapidity with which the normal circulation is impeded. I shall use the terms intestinal obstruction, occlusion, and ileus as synonymous. Their symptoms are as follows:

1. Acute cases. There may be an antecedent history of one or more attacks of acute appendicitis, or "peritonitis," of greater or less severity, or there may have been mild attacks of simple dis-

comfort in the lower abdomen with intestinal disturbances, not sufficient to incapacitate, and not pronounced enough to be absolutely diagnosed as appendicitis, yet which may make us suspicious of chronic appendicitis, or there may have been a history of previous colitis, in which we know that the appendix has a great tendency to become involved, although it may not be recognized as such. Succeeding an attack, or attacks, of any of the above types, after an interval varying from months to many years, there suddenly develops, either without any known reason, or following some indigestible meal, or abdominal blow, or over-exercise, an attack which at first looks like simple intestinal colic. Unlike this, however, it does not yield to any treatment; pressure on the abdomen cannot be borne as is the case in simple colic. There is intractable vomiting, which is an early and constant symptom in all acute obstructions. This vomiting begins with eructations of gas and mucus, followed later by stomach contents mixed with bile, then pure bile, which is succeeded by a brownish, and finally a fecal vomitus. The higher the obstruction in the bowel, the more violent is the vomiting, and the earlier it makes its appearance. When the obstruction is in the jejunum, or upper part of the ileum, the vomitus is never really fecal. True fecal vomiting can come only from an obstruction to the lower ileum or colon. The vomiting is intensified by anything which increases peristalsis, such as food or cathartics, and yields to no treatment. A striking peculiarity is that when vomiting once begins it usually continues to the last. It is at first violent with exhausting retching, but later each act is marked by temporary relief.

Pain is a constant and early symptom, being at first paroxysmal, corresponding to the violent attempts of the intestine to force its contents by the obstruction. The pain soon becomes continuous, although there are periods of partial relief. The more absolute the obstruction, the less intermittency there is to the pain. Pressure on the abdomen increases it. The site of the pain,

* Read before the Medical Association of the Greater City of New York.

in the beginning, is usually at the umbilicus, since it is referred to the solar plexus, from which it is reflected to the umbilical region, hence the seat of pain in the beginning is no guide to the location of the obstruction. It is intensified by anything which increases peristalsis, such as food or purgatives. Later, as the obstructed intestine becomes distended with gas and decomposing fluids, and the peritonæum becomes inflamed and swollen, the pain is constant and severe, and is localized about the affected region. The supervention of gangrene in the obstructed bowel is marked by diminution in the pain, provided peritonitis has not already arisen. Obstruction in the large bowel excites but slight pain, due to the fact that peristalsis in the large intestine is normally much less active than in the small.

Constipation becomes more and more complete as the case progresses. Enemata at first may cause the escape per rectum of the gas and the feces which are in the intestines below the point of constriction, which fact may mislead, and cause precious time to be lost in vain attempts to open the bowel. Cathartics likewise tend greatly to exhaust the patient because of the increased violence of peristalsis caused thereby, with its consequent greater pain and expenditure of nervous energy.

Distention gradually increases in the intestines above the occluded point. In intestinal obstruction resulting from appendicitis, the site of obstruction is always in the small intestine, and most frequently in its lower region. Meteorism is most prominent in the mid part of the abdomen, and, in the acute cases, not usually so sufficiently localized as to be perceptible by palpation, or inspection, as confined to a definite loop. Distention in this variety of obstruction is rarely conspicuous until peritonitis supervenes, because the constant vomiting and eructations of gas serve to relieve the accumulation. Later on, distention, due to the peritonitis with its consequent paralysis of the intestines, even without perforation, may become very diffuse and general, and embarrass the heart and lungs by pressure. Perforation may occur, and give the signs of free air and fluid in the peritoneal cavity. The higher up the obstruction is situated, the less is the distention.

Abdominal rigidity and tenderness at first are very slight, and limited to the portion of the abdomen in front of the constricting point. There may be some general cutaneous hyperæsthesia. Later on, as the peritonæum becomes involved, the rigidity and tenderness both are marked, at first localized, then becoming more and more general as the peritonitis spreads. The intestine at

the constricted point may become so distended with fluid as to give rise to a localized area of dullness.

A mass is usually not palpable in the case of an obstruction by a simple band. A volvulus or hernia may give the sensation of an indefinite mass, but this is the exception.

The pulse at the outset may be rapid and feeble, from sudden shock to the abdominal sympathetic. In this it differs from simple intestinal colic, in which the pulse remains full and not rapid. As the shock is recovered from, the pulse approaches somewhat the normal, or may be even slower than normal. Later it becomes rapid and feeble as the peritonitis spreads, or the poisonous intestinal contents are absorbed.

The leucocyte count is usually of little help. In the first case to be reported, with 23 inches of gangrenous gut, it was a trifle above the normal. Harvey Cushing, in 1898, concluded that a leucocytosis of 18,000 to 20,000, in patients presenting symptoms of obstruction, was pathognomic, and sufficient to form a rational basis for operative interference. Bloodgood has recently expressed very similar conclusions, and affirms "that in the majority of instances the leucocyte count is from 15,000 to 20,000: higher counts, 25,000 to 35,000, are usually associated with gangrene or peritonitis." This question of the value of the leucocyte count in abdominal diseases is a much vexed one at the present time, and a satisfactory interpretation of the varying counts has not yet been arrived at. The earlier promises that this examination held out have not as yet been fulfilled, for many of us have learned by sad experience not to place a great deal of dependence upon it. It is only of value when considered in conjunction with all the other signs. A low count, with the other cardinal symptoms well developed, should be left out of consideration when debating the pros and cons of an operative procedure, since we have often found that there may be a normal leucocyte count with the abdomen full of pus. This low count simply means that the system is too overwhelmed and depressed to manufacture sufficient leucocytes to combat the sepsis. A high count would mean that some grave condition was present, such as gangrene or perforation, and it would simply strengthen our view that some operative interference was urgently required. It is also of interest to note that as soon as symptoms of general septicæmia are present, bacilli coli communes may be found both in the urine and blood (Gallazzi).

The condition of the urine in patients with ileus

has received much study. It is usually scanty in amount. Carter called attention to the presence of indican. According to the experiments of Taffen, Orthweiler, and Nothnagel, increased indigo secretion requires the presence of sufficient albuminoid material in the state of intense putridity, and the absorption of formed indol. The results of these experiments in occlusions of the small bowel showed that the formation of indican began after twenty-four hours, and reached its maximum on the third day. It is absent, or present in very small quantities, in occlusions of the large bowel. In diffuse peritonitis it is generally present in large quantities, as is also the case in typhoid fever, intestinal tuberculosis, empyema, putrid bronchitis, etc. "Diagnostically the appearance of abnormally large quantities of indican in the urine indicates merely that there is abnormal putrefaction of albumin somewhere in the body. Farther than this we can rarely go, and it is a precarious matter to make a special diagnosis on the basis of increased indicanuria, for we must never forget that simple coprostasis may lead to a great increase of the urinary indican" (*Ref. Handbook of the Med. Sciences*, Vol. VIII, page 45).

The patient with acute intestinal obstruction is early much prostrated, and the physiognomy is characteristic of grave nerve depression. The face becomes drawn and anxious, the eyes sunken, beads of perspiration stand out upon the forehead, the extremities are cold, and the respirations are shallow and hurried. There are great thirst and at first restlessness which later changes into apathy. The higher the lesion, the greater is the shock, owing to the more intimate association of the upper part of the bowel with the sympathetic nervous system. Shock and later collapse are due partly to nervous disturbance, partly to the absorption of toxic materials, and partly to the withdrawal of fluid from the body, as a result of the vomiting; the portal area is also much engorged, and this adds to the want of fluid in the systemic circulation.

The stethoscope, applied to the abdomen, will enable one to hear at first very violent peristaltic sounds, possibly heard with greatest intensity over some one portion of the abdomen, which later may be found to correspond with the anatomical position of the obstruction. It is of particular diagnostic worth if there is at the same time a local distention of the abdomen. Later, as the peritonitis advances and the intestines become paralyzed, peristaltic sounds are fainter and fainter.

There may be free fluid appreciable in the ab-

domen early in the disease. This is comparable in its genesis to the fluid found in the sac of a strangulated hernia, and occurs sometimes before meteorism becomes at all marked, which renders its detection easy: if the patient be examined frequently its increase hour by hour may often be noted.

It must be remembered that the early symptoms of acute intestinal obstruction are caused by strangulation of the blood current, and not by mere obstruction to the faecal stream. The latter (obstruction to the faecal current) when present alone, as in cancer of the bowel wall, causes very slow and chronic symptoms.

Rectal and vaginal examinations should never be omitted, and the external hernial openings should be palpated for a possible strangulated hernia.

The pathology of the condition may be stated in a few words: as a result of peritoneal inflammation, two loops of intestine become adherent by their peritoneal coats, or a loop may become adherent to the parietal peritonæum. Subsequently, as the respective loop, or loops, drag on this point of adherence, the peritonæum becomes drawn out into a band of greater or less thickness and length. The inflammatory products in this band become organized into connective tissue and we have a permanent fibrous structure remaining, which has a great tendency to contract. The appendix itself may act precisely as a band, becoming adherent by its tip to the parietal peritonæum, to the mesentery, to the intestine, to the uterine annexæ, etc. In these 33 reported cases, the appendix was the obstructing band in eleven cases. In any case the band predisposes to a dangerous condition, for it may lead to any one of several occurrences. A band, attached to an intestinal loop, by its contraction may draw the intestine out into a spur, whose free peristaltic movements are lessened by the adhesion, both causes consequently placing an obstacle in the way of the circulation of faeces. As the stasis increases, the kink increases, until finally the obstruction is complete. Or, again, a band may become attached by its two extremities to a loop of intestine parallel to its long axis. Contraction of this band may produce either a kink or a torsion of the intermediate portion of bowel. Or a band may be formed in front of a piece of intestine which it compresses. An attack of acute indigestion may distend the intestine above the loop, and the increased distention and peristalsis may cause it to kink so as to obstruct its lumen, and cut off the circulation at this point; or a complete kink may be caused by some sudden blow

or exertion. A loop of intestine may force itself beneath this band, and, by the same causes acting as above, a twisting, or volvulus, be produced beyond the band, cutting off the circulation of blood and feces. Again, a band may form the partial boundary of an opening through which a loop of intestine may force itself and become strangulated, and we then have an internal, strangulated hernia. A loop of ileum may become attached to the small intestine in immediate proximity to the inflamed appendix. These two loops may suddenly become twisted about their points of attachment, so as to produce complete obstruction. There may also be formed true knots of the intestine. Unless each of these conditions is speedily relieved, gangrene of varying lengths of the intestine, from cutting off of the vascular circulation, may supervene, resulting in perforation and fatal general peritonitis. A localized abscess is rarely formed, because perforation is so rapid as to occur before protecting adhesions have a chance to form, which would wall in the abscess and thus prevent infection of the general peritoneal cavity.

Obstruction is not so apt to occur during the first attack of appendicitis as some time afterwards, since, during the first attack, the adhesions are soft and yielding, not yet having had time to organize.

Kocher (*Mittheil. aus den Grenzgeb. de Med. und Chir.*, 1898, page 227, Vol. IV) lays down in part the following propositions: 1. The chief danger in each case of ileus rests upon the disturbances in circulation in the bowel wall, and its consequences, namely, venous hyperemia leading to hæmorrhages, and infarcts, oedematous infiltration, and the collection of decomposing fluids in the intestine, injury and exfoliation of the epithelium, and the consequent permeability of the bowel wall for the passage of ferments, toxic substances, and bacteria. 2. This permeability leads, on the one hand, to general intoxication and infection, and, on the other hand, to local inflammations of the bowel walls, necrosis of the same with ulcerations, perforations, and peritonitis. 3. The circulatory disturbances in the intestinal walls are caused by pressure, first, from without upon circumscribed portions of the wall, and also by pressure upon the mesenteric vessels, due to strangulation by bands, internal herniæ, volvuli, invaginations, etc. Secondly, the disturbances in the circulation in the intestinal walls are caused by pressure from within by the stagnation of the intestinal contents, increased transudation, and secretion above the obstruction, and the consequent overstretching of the bowel walls.

As a result of the previous inflammations, we may find that the appendix itself is simply a band of connective tissue, its lumen having become obliterated by the antecedent inflammations.

2. The chronic types of intestinal obstruction, resulting from inflammations in and about the appendix, are rarer. Following the original appendicitis, there may be a longer or shorter period of perfect health. The patient then begins to complain of digestive disturbances, particularly from the side of the bowel activity. Constipation becomes more and more marked, relieved with greater and greater difficulty by cathartics and enemata. This constipation may alternate with occasional watery diarrhoea, due to catarrhal enteritis, caused by the irritation of retained, decomposing feces above the constricting point. There may be attacks of intestinal colics with nausea and vomiting, relieved by thorough evacuation of the bowels. These attacks recur at irregular intervals, and are due to temporary obstruction, above the constricting point, of a mass of undigested, impacted food or feces. A diagnosis may be made at this time, and that, too, much to the patient's advantage, for abdominal massage and electricity may so stretch the adhesions as to prevent their contraction, and thus ward off complete obstruction. Careful watching of a patient with a history of appendicitis, or one which makes us suspicious of a chronic appendicitis, and who has the above symptoms, will enable the right diagnosis to be made. Oftener, however, that of intestinal indigestion is made and the patient is plied with drugs, and placed upon a more and more rigid diet when the symptoms do not yield, with the result of causing loss of flesh and strength, at times of extreme degree. Chronic obstruction is caused by the gradual contraction of adhesions between two loops of bowel, or about a loop, or by the gradual or periodic forcing of a coil beneath a band, etc., resulting in the progressive diminution in the calibre of the bowel. Persistence of these symptoms urgently requires operative interference. Sudden complete obstruction may come on at any time without obvious cause, or determined by an overhearty meal (acute intestinal indigestion), violent exertion, or injury. The symptoms then of complete acute obstruction are in full evidence, requiring active operative treatment. The severest forms of ileus begin slowly. This fact I wish particularly to emphasize.

Diagnosis.—The all important point to determine is whether a true mechanical obstruction is present or not, irrespective of its ætiology. I shall not go into the various and numerous causes of

mechanical occlusion, many of which cannot be determined until the abdomen is opened. To delay because the exact cause is not apparent and in order to determine this cause, is a fatal mistake. In not a few cases we must ask with Weir, "not what the cause is, nor where the obstruction lies, but is there an obstruction?" The typical cases are usually plain enough as to diagnosis, it is the atypical ones which puzzle us, those which lie on the borderland between true mechanical obstruction and adynamic obstruction, in which symptoms of transient ileus lead us astray. The diagnosis of either of these conditions generally presents difficulties only in the beginning stages, but it is just at this time that in a correct diagnosis and proper treatment lies the patient's future welfare.

The investigation of a patient with a possible intestinal obstruction should proceed somewhat as follows:

1. The history of the patient for years previous should be carefully gone into, to find any trace of inflammation of the peritonæum, due to sepsis in the appendix, gall bladder, tubes, or resulting from leakage of an old perforating gastric or duodenal ulcer, causing adhesions. We may be able frequently from such data to make a provisionally correct diagnosis.

2. The history of the present attack should then be investigated, noting particularly the manner of onset, whether acute or gradual, the duration of the symptoms, and whether there have ever been previous subacute attacks. Careful inquiry should then be made as to the occurrence of vomiting and the character of the vomitus, onset, location, and severity of the pain, passage per rectum of flatus and fæces, character of the stools, if there have been any, the amount and position of the abdominal tenderness as noticed by the patient, and also the extent of the prostration.

3. A most careful, methodical, and painstaking examination of the patient should then be made. The physiognomy and the general condition, as well as the absence or not of signs of prostration, should be noted. The general attitude should be observed, whether the patient lies with knees drawn up, his ability to turn on the side, the amount of restlessness, the type of respiration, whether abdominal or thoracic, etc., etc.

4. Inspection should determine the amount of the general abdominal movements during respiration, whether there be any inequality in the amount of the movement in the various segments of the abdomen, also the presence of any prominence such as would be caused by an underlying tumor. The existence of visible peristalsis or en-

larged coils of intestine should be looked for; such are rarely seen in the acute types, but may be evident in the chronic ones. The amount and character of the distention are studied, and whether or not it is located in the centre of the abdomen, as when small intestines are involved, or in the flanks, as occurs when the obstruction is in the rectum or sigmoid.

5. Palpation should elicit a point or points of tenderness and their general and relative intensity, general or localized muscular rigidity, presence or absence of a tumor, and, if present, its size, shape, character, etc., presence of rigidity of one costal arch more than the other (Eliot), etc. All the normal and abnormal hernial openings are investigated, as are also the rectum and vagina. The heart and lungs are carefully gone over.

6. Percussion will reveal the presence or absence of free or encapsulated fluid, or free gas in the abdominal cavity. Local dullness may signify a loop of intestine distended with fluid.

7. Auscultation will enable us to determine by the peristaltic sounds the presence and amount of local or general intestinal paralysis, as well as any point of increased peristaltic movements, such as we find just above the constricting point in the early stages.

8. Changes in the temperature and the pulse are carefully and frequently noted, and interpreted accordingly. The urine is examined as usual and, in addition, the amount of the indican is determined. The blood is counted for the number of leucocytes, and the result interpreted in conjunction with the rest of the symptoms.

Some difficulty may be met with in distinguishing a true mechanical obstruction from the obstructive symptoms associated with localized enteritis, or peritonitis, such as occur in appendicitis when the intestinal walls are paralyzed. This pseudoileus is at times so pronounced as to lead to fæcal vomiting, but careful attention to the history, general symptoms, and condition of the patient will enable a correct diagnosis to be made. The following table (Rose and Carless) gives the chief diagnostic points:

	ACUTE INTERNAL STRANGULAR OBSTRUCTION.	ACUTE APPENDICITIS WITH PERITONITIS.
Onset.....	Abrupt.....	May be preceded by local pain.
Rigor.....	Absent.....	Often present.
Temperature..	Subnormal at first; rising at onset of peritonitis.....	High at first, falling later from exhaustion or toxæmia.
Pain.....	Severe; referred to the umbilicus.....	Severe, primarily referred to the right iliac fossa.
Tenderness....	Absent till peritonitis comes on.....	Present over cæcum even in early stages, and gradually spreading.
Vomiting.....	Early, marked, and soon fæcal.....	Less urgent and seldom fæcal, except as a late symptom.
Abdominal wall	Flaccid till peritonitis is present.....	Tense and rigid from the first.

Jennings (*Lancet*, March, 1904, page 793) says, "excluding external herniæ, internal strangulations are far the most important variety of obstruction to diagnosticate early, for 1, they are frequently of such a nature that the surgeon can completely relieve them; 2, unless relieved they will quickly kill; 3, they usually come in previously healthy adults in the prime of life; and, 4, there is usually no concomitant disease likely to kill the patient."

Treatment.—Prophylaxis consists in careful regulation of the diet of a patient who has had an attack of appendicitis, for from four to six weeks after such an attack, in order to avoid acute indigestion. Constipation should be guarded against, and attacks of gaseous indigestion with colicky pains should be carefully watched, and treated promptly and vigorously. It has occurred to me that it would be rational to employ gentle abdominal massage, either with the hand or the cannon ball, beginning four or five weeks after every acute appendicular inflammation, in order to stretch and loosen the adhesions.

Ileus occurring within four or five weeks after the original appendicitis, is more likely to yield to palliative treatment than that occurring after a greater lapse of time, for in the former case the adhesions are softer and more yielding. At the onset of the attack, while the diagnosis is as yet uncertain, an initial cathartic with repeated high enemata, gastric lavage, gentle abdominal massage with frequent changes in the position of the patient, together with electricity to the abdomen, are all in order. An initial dose of morphine is permissible, but none further should then be given, for the symptoms are thereby masked, and the diagnosis is obscured. The diagnosis should be made within the first twenty-four hours of the onset, when further palliative attempts to overcome the obstruction should be desisted from, since these simply exhaust the already prostrated patient. Fæcal vomiting should never be waited for! The treatment now is expressed in the one word, laparotomy, and that, too, at the earliest possible moment, for statistics show that the mortality of the operation rises appallingly with each hour of delay.

It is not my purpose at this time to go into the details of the operative technique to any great extent: suffice it to say, that there are two main objects to be accomplished: 1, to empty the distended bowel, since the patient is being slowly poisoned by the absorption of the septic contents; 2, to remove the cause of the obstruction. A general anæsthetic is to be preferred, except in most desperate cases, where cocaine may be used lo-

cally. To prevent the patient drowning himself with fæcal vomitus, it is advisable to wash out the stomach prior to the operation, and to have the head lower than the body during the operation. An incision in the median line below the umbilicus is made and search at once instituted for the cause of the obstruction. This may be difficult on account of the distended condition of the intestine. This latter may be partially overcome by aspirating the bowel, or better by opening it in one or more places, care being taken to prevent soiling of the peritonæum, the openings being subsequently closed by two rows of Lembert silk sutures. If the case be *in extremis*, an artificial anus may be at once established, leaving the obstructing cause to be removed later. Usually it will be possible to institute a methodical search for the cause of the obstruction. If this is not evident at once, a distended loop should be drawn into the wound, and followed along in the direction of increasing distention and tension until the occluded point is reached, which should then be treated as the individual conditions require; kinks, adhesions, herniæ, twistings, etc., are all freed, and the intestinal contents above the obstructing point massaged into the collapsed portion below. If the gut wall is so damaged as to threaten perforation, or if it is already gangrenous, we may proceed in two ways: 1, by resection of the damaged area with end to end anastomosis; or, 2, by the formation of an artificial anus. The former gives better results in the majority of cases, and is much to be preferred. Search should always be made for a second point of obstruction, since sufficient cases are already on record to show that surgeons have been satisfied to remove one obstruction without searching for a second, which autopsies have revealed to be present and fatal. Before leaving the table, the stomach should again be washed out.
